NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

*"To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

THURSDAY, NOVEMBER 2, 1905.

TWO TEXT-BOOKS ON MECHANICS.

An Introduction to the Design of Beams, Girders, and Columns in Machines and Structures, with Examples in Graphic Statics. By W. H. Atherton. Pp. xiv+236. (London: Charles Griffin and Co., Ltd., 1905.) Price 6s. net.

Mechanics for Engineers, a Text-book of Intermediate Standard. By Arthur Morley. Pp. xi+282. (London: Longmans, Green and Co., 1905.) Price 4s. net.

MR. ATHERTON'S book is for engineering students whose mathematical knowledge does not include the calculus. and such readers will find it a very useful source of information.

The style is very unconventional—a trait which is rather helpful than otherwise—but occasionally the disregard of grammatical niceties and the ordinary rules of composition is carried too far.

The author does not trouble himself in the least about discussions as to absolute and gravitation units of force and the so-called "engineer's unit of mass" (which is about 32·2 pounds). He is a practical engineer, as is sufficiently obvious from the words, "There are only two units of force that will be of much use to us—namely a *pound* for light work and a *ton* for heavy work"; but there is a suggestion of an ancient conundrum about his statement, "So far as we are concerned, force is measured in terms of some unit of weight, as that of a ton of iron." Chapter vi. contains a good exposition of the theory of the bending of beams, together with some useful cautions and explanations of certain discrepancies between theory and practice. The moments of resistance of beams of various cross-sections are all calculated by elementary non-calculus methods. The calculation of moment of inertia (the absurdity of which term the author very properly emphasises) is made in the same manner. It would be a great help to students—even to those who can use the calculus—to give the *particle rule* for calculating all moments of inertia with reference to a triangular (and thence any polygonal) area; the moment of inertia of a triangular area about any axis whatever can be calculated by replacing the triangle by three equal particles at the middle points of the sides, their masses being represented by $\frac{1}{3}\Delta$, where Δ=area of triangle.

While the whole of the book will be found useful, the chapter on the comparative strengths of tubes of various forms may be specially mentioned.

Mr. Morley's work differs from that above noticed in excluding all technical knowledge and terms, so that it is suitable to all students of dynamics, whether engineers or not. It does not employ a knowledge of calculus, its range being covered by algebra and elementary trigonometry, and its scope being that of the London intermediate engineering examination and that for the A.M.I.C.E. The work adopts the plan of founding the science of force on Newton's axiom ii., so that kinetical principles precede the treatment of equilibrium (statics). The great importance of the direct application of the principles of momentum and energy is recognised at the outset by supplying a large number of excellent examples of these principles, so that the work is thoroughly modern in conception and method. There is a large and commendable use of squared paper diagrams for calculating velocities, forces, work, &c., in cases in which these are variable according to other than the most simple laws.

The poundal is, happily, not employed, but the "engineer's unit of mass" is adopted in order to save the definition of force, viz. "force is the rate of change of momentum." It is doubtful if many students are helped by this device, or if they really understand what they are doing when they say that the mass of a body is W/g. We must confine ourselves to a few brief observations on a work which we commend very highly. Is not a "knot" a speed—a geographical mile per hour? The newspapers sometimes speak of "20 knots an hour," so does the author (p. 20). It is a pity that he speaks of "accelerating forces" (p. 43, &c.), because it is

essential to teach a student that *acceleration* is the inevitable property of *every* force. The motion in Atwood's machine is calculated first by the strictly valid method of introducing the tension, and then by the old method of "mass moved $= W_1 + W_2$; accelerating force $= W_1 - W_2$, &c.," which latter should either be unmentioned, or, if mentioned, justified (if possible). The formal statement "when a force acts upon a body and causes motion, it is said to do work" (p. 48) is very dangerous doctrine. The tension of an inextensible pendulum cord certainly does no work, though it exists in the motion. Are we to suppose that safety is contained in the word "causes"? If so, the metaphysician must be heard. On the important and almost universal fallacy concerning "centrifugal force" the author is a clear and safe guide.

A large collection of the ordinary statical problems is followed by a discussion of centres of gravity, moments of inertia and rotatory motions of rigid bodies, and a chapter on graphic statics, the whole being illustrated by a large collection of very well chosen examples. M.

INDUCED RADIO-ACTIVITY.

Radium and Other Radio-active Substances; their Application especially to Medicine. By Dr. Charles Baskerville. Pp. 164. (Philadelphia: Williams, Brown, and Earle, n.d.)

PROF. BASKERVILLE'S book is disappointing. On opening a work on a scientific subject by an original worker in the field of which it treats one expects to find the original materials thoroughly digested and worked up, and the relative merits of rival theories and conflicting experimental data carefully weighed; one hopes, too, to find novel suggestions for the interpretation of existing data, and hints to guide experimental research in the future.

In the present work these things are not to be found. It may be said, broadly, that the book is no more than a collection of abstracts of original papers, put together, indeed, in some approach to a consecutive order, as regards subject-matter, but without the attempt to weld them into a homogeneous whole. We constantly find, for instance, that views which have no serious claims to attention, either from the authority of their authors or from the arguments they put forward, are treated with quite as much respect as the opposite conclusions of leading workers in the subject, which are supported by strong experimental evidence.

In some cases the author even goes so far as apparently to endorse conclusions which are opposed to his own. On p. 88 we have a picture, underneath which the following explanation is given:—

"This is a radiograph of a gold fish which had been placed in water rendered radio-active by having suspended in it for 24 hours a *closed tube* (our italics) containing ten milligrams of radium of high activity. By this process the water was rendered radio-active, and the fish was then placed in the water, and, although the radium had been entirely removed, the fish itself was rendered radio-active, and, when placed on a photographic plate, photographed itself by its own radio-activity."

As Prof. Baskerville, contrary to his usual custom, mentions no name in connection with this experiment, we assume that it is his own. None the less, we read, on pp. 92–93:—

"Piffard calls attention to the fact that no authoritative statement has been given as to the rendering of water or other substances radio-active by the presence of a closed tube of radium. He further detected defects in tubes, air bubbles, &c., and regards the statements concerning induced activity by means of closed tubes as based upon the use of defective tubes. As Curie and Rutherford have shown, induced activity requires a naked exposure to radio-active bodies."

For our own part, we have no belief in radio-activity having been produced in the fish under the conditions described. The photographic effects may have been due to imperfect closing of the tube of radium, or they may have been produced by some direct chemical effect of the fish's skin on the film. But however that may be, the author's attitude in emphasising equally two opposite statements is not intelligible. Prof. Baskerville has shown great industry in bringing together the results of different experimenters, but we cannot think that he has presented his collection judiciously.

GARDEN CITIES.

Garden Cities in Theory and Practice. By A. R. Sennett. Vol. i., pp. xix + 557. Vol. ii., pp. xii + 558. (London: Bemrose and Sons, Ltd., 1904.) Price 21s. net.

THESE two handsome volumes represent the amplification of a paper on "The Possibilities of Applied Science in a Garden City" which was read by Mr. A. R. Sennett before Section F of the British Association in 1903.

The author first deals very fully with the engineering problem involved in the laying out of garden cities. A comparison of the various plans on which the great cities of the world have been built is given in a most lucid and interesting manner, after which the author shows with many clear and convincing arguments that the best type is that known as the rectilinear configuration, which is the one he adopts —the worst of all being the curvilinear type, not only from an æsthetic, but also from a practical point of view.

An interesting account of the rebuilding of London after the great fire is given in chapter ii. The various plans, especially those of Sir Christopher Wren and Sir John Evelyn, are fully discussed. The plan of the former was more or less adopted, although all his proposals were unfortunately not adhered to, with the result that many fine architectural effects are lost to the metropolis. We cannot do better than recommend those who are interested in this important subject to read the author's own account, which should excite interest even in the apathetic. In regard to the spacing out of the area for his proposed garden city, the author has carefully considered every

detail. The proportion of the area to be occupied by the public thoroughfares, promenades, avenues, and private gardens is fully discussed. By a most ingenious and original plan of allotment, each house in the city stands in its own ground without being unduly overlooked or interfered with by neighbouring dwellings, but at the same time fitting harmoniously into the whole. Instead of the usual oblong or rectangular arrangement, the author subdivides the ground into polygonal or, more precisely, hexagonal plots. This he shows preserves a uniform frontage length, and at the same time admits of great elasticity as regards the size of the allotments which different inhabitants may desire.

The city proposed by the author would consist of three separate areas, viz. the city proper, the village with its industrial zone, and the agricultural fringe. Each department is so arranged and laid out that the maximum amount of comfort and utility is combined with the minimum amount of expense. The city as a whole is so designed that it shall be self-supporting. All needless expense and extravagance are scrupulously avoided. The artisan's dwelling is made for the artisan, and the same applies to the housing of every grade and class of society. All are suitably provided for. Public buildings and offices, railway stations, &c., are grouped together within easy access of each other in the centre of the city.

The sanitary and hygienic conditions of every kind are treated in an able and scientific manner. Every health-promoting device that ingenuity can suggest is brought forward in its proper place. It is beyond the scope of a review to mention these in detail. Suffice it to say that nothing is suggested which cannot be easily put into practice; and, further, many of the author's valuable and common-sense suggestions might with great advantage be adopted in our present cities.

The sociological aspect of garden cities is treated in a rational and scientific manner. The doctrine of "equality" which was urged by some when the site of the first garden city was acquired is relegated to its proper place by the author, who reminds his readers that the outcry for equality has proved the curse of industrial England, and points out the absurdity of ranking the "loungers- the quasi-inert and industrially passive atoms—as of equal national value to the active workers or energy-imparting unit." The decentralisation of industry is one of the great objects of garden cities—hence the authorities can deal with nothing below the industrial unit.

Under the heading "Charity" the problem of dealing with the poor and infirm is discussed. The various pitfalls and dangers attendant upon indiscriminate charity are shown by actual examples. The problem is a serious one; but in this, as in other cases, the author finds a way of overcoming the difficulty, especially as regards garden cities which are untrammelled by established practice or tradition, and where methods such as the Elberfeld system, so successfully adopted in the town of that name and in Leipzig, and which the test of time—half a century - has proved to be sound in principle, might quite easily be put into practice.

The work contains a wonderful amount of valuable information written in a readable style, while the illustrations are numerous, well chosen, and admirably reproduced.

OUR BOOK SHELF.

Elementary Experimental Chemistry. By A. E. Dunstan. Pp. viii + 173. (London: Methuen and Co., 1905.) Price 2s.

So many books on elementary chemistry have been published within the last few years that it is rather difficult to imagine why any more should be written, unless there is something strikingly novel in the style or matter of the book. For anything novel we search in vain in the little book before us.

After being introduced to the metric system, in chapter ii. the student is supposed to find out the difference between chemical and physical changes by having to note the effect of heat upon sulphur, lead, magnesium, and sugar, and at the end of each experiment he has to state whether the change is physical or chemical. Chapter iii. deals with air, chapter iv. with active air. In chapter x. we come to solution, which to our mind would have been better treated earlier.

Formulæ are not mentioned until p. 130, and on p. 131 the union of atoms to form molecules is shown in a diagrammatic manner which we venture to think will leave the student very little wiser than before. Almost all through the book the equations are written in words and not expressed in symbols, as, for example, zinc + sulphuric acid = zinc sulphate + hydrogen. This is not necessarily objectionable in an elementary book, but to formulate all the equations which occur in the course of the book in an appendix is simply wasting type, because the student will never look at them. Furthermore, will the student understand the action of nitric acid upon copper by writing the equation in this manner?

$$2HNO_3 \left\{ \begin{matrix} 2\,N\,O \\ H_2O + 3Cu = \\ 3\;\;O \end{matrix} \right\} 2NO + H_2O + 3CuO.$$

It is then explained that the copper oxide is acted upon by a further quantity of nitric acid, &c.

Some of the experiments which the student is supposed to carry out are more for the lecture table than for the laboratory. For instance, on p. 121 the student has "to find the proportions in which oxygen and hydrogen combine to form water." Dry hydrogen and oxygen have to be collected in a eudiometer *over mercury* and then sparked. On p. 122 a similar experiment has to be carried out, but in this case to show the volume of steam formed. These are not experiments for elementary students, and we doubt whether the author himself allows his students to carry them out.

The book is very fully illustrated, and some of the exercises are undoubtedly good, but for the book to be really useful to the student will require a considerable amount of discrimination on the part of the teacher as to what experiments the student can himself be trusted to work out.

Wayside and Woodland Blossoms. By Edward Step; with coloured pictures by Mabel Step. First series, pp. xiii + 176 + 127 plates. Second series, pp. xv + 171 + 127 plates. (London: Frederick Warne and Co., 1905.) Price, each volume, 6s. net.

ABOUT ten years ago Mr. Step prepared two handy little volumes which many country ramblers have

found of service in identifying British wild flowers and discovering something about their affinities and the significance of their structure. These volumes have now been completely re-arranged, and the plates have all been newly drawn, so that the revised edition is substantially a new work. In the original books, plants were roughly arranged in the order of the seasons in which their flowers appear, but in the present volumes a more natural grouping is followed, series i. containing representatives of the plant families from the Buttercups to the Composites inclusive, and series ii. from the Composites to the Grasses and Ferns. This arrangement is much more instructive than the former one; and in connection with the descriptions of family characters given at the end of each volume it should facilitate the further study of plants in more elaborate works.

The coloured plates in the two volumes are, with few exceptions, very fine, and will enable the country rambler easily to identify the flowering plants he meets. In almost every case the pictures are truer to nature than those in the original volumes, though these left little cause for complaint. The picture, for instance, of Lady's Smock is much superior to that in the old edition; so is that of Germander Speedwell. The Chicory flower, however, is better represented in the old volume than in the new; and in neither is the illustration of Tamarisk satisfactory. The ideal way to depict flowers for purposes of identification would be to take tri-colour photographs of the flowers and reproduce them by the three-colour process of printing. This method, which has been successfully adopted in the illustration of a few natural history objects, might have been profitably used by Mr. Step instead of lithography. No doubt there are difficulties to be overcome, but they are not very great, and success should attend the work in which the advantages of colour photography are brought into requisition. But while we await these faithful photographic reproductions, it is good to possess Mr. Step's two pocket guides with their clear descriptions and plates, and we are glad that such attractive books exist to awaken interest in plant life.

Quiet Hours with Nature. By Mrs. Brightwen. Pp. xvi+271. (London: Fisher Unwin, 1904.) Price 2s.

MRS. BRIGHTWEN'S books no longer need to be recommended to beginners in natural history. A fresh collection of her simple and sympathetic accounts of animal and vegetable life as studied and enjoyed in her own garden and park is sure to be welcome to all boys and girls who have once begun to take an intelligent interest in natural objects. All we need say about this volume is that, besides some pleasant papers about her tamed wild animals, including squirrels, field-voles, a rook, and even a stag-beetle, which followed his benefactor across the lawn, it contains others on the trees in her garden and some of the plants in her conservatory, all well calculated to arouse just such an interest in common things as may carry the young reader on to more exact and elaborate studies of nature. The book is charmingly illustrated by photographs and drawings.

One word of criticism may be allowed. It is surely as well, in introducing young folks to the study of nature, not to lead them to think that there is an essential difference between the "professional" entomologist or ornithologist and the ordinary observant field-naturalist; or if there be a real difference, it may be as well not to emphasise it. On p. 191 Mrs. Brightwen quotes a scientific description of the head of *Eristalis tenax*, with the comment:—"Now this may be very interesting to a professional entomologist, but it does not convey much information to an ordinary reader, and yet this is the scientific description of my drone-flies, interesting creatures which I kept through a whole winter until they were coaxed into the circle of my winged friends." It is true that the description conveys but little to an "ordinary reader," but a very little trouble will make it convey a great deal, and this small amount of trouble, or of instruction if it can be had, is exactly what our young "nature-lovers" should be encouraged to face. As it happens, the example of Eristalis is a good one; for the history of its confusion with the bees is a most interesting one, showing how much delusion may arise, and not only delusion, but myth, merely from the want of a little knowledge of structure.

Sammlung Schubert, XLII. Theorie der Electrizität und des Magnetismus. Vol. ii. By Prof. Dr. J. Classen. Pp. ix+251; with 53 figures. (Leipzig: G. J. Göschen'sche Verlagshandlung, 1904.) Price 7 marks.

THIS forms the second part of an introductory text-book of electricity and magnetism in which chief stress is laid on the mathematical side. In this volume the Faraday-Maxwell conception of electrical phenomena still forms the central idea; but, since the representation of simple magnetic phenomena in terms of a distribution of energy in a medium presents considerable difficulty from the mathematical standpoint, the classical conception based on action at a distance is retained, but regarded merely as a mathematical device and not as a physical conception. In the section on electromagnetism the author adopts the special form of equations developed by Hertz in his paper on the fundamental equations of electromagnetism for bodies at rest, and expresses his strong opinion in favour of generally adopting these in all treatises of mathematical physics.

Only one part of Maxwell's characteristic treatment of the subject finds no place here, and that is his demonstration of the connection between the fundamental equations of electricity and the general Lagrangian equations of mechanics.

Vegetationsbilder. By Drs. G. Karsten and H. Schenck. Third series. Parts i.–iii., containing plates i.–xviii. (Jena: Gustav Fischer, 1905.)

BOTANISTS who possess the first two series of the "Vegetationsbilder," or who have had the opportunity of admiring these magnificent series of photographic reproductions, will be glad to see that the third series is rapidly taking shape. The subject of epiphytic flower-gardens arising out of ants' nests, which formed part of a previous number, by Mr. E. Ule, is more fully treated in the first part of this series by the same authority. The ant-gardeners are species of Azteca, most often *Azteca Traili* and *Camponotus femoratus*. The plates represent different stages in the formation of the gardens; the plants which develop from seed brought in by the ants are chiefly aroids, bromeliads, and species of Gesneraceæ. In the second part Mr. E. A. Bessey presents a study of the sand-dunes, shifting and stationary, of Russian Turkestan with a vegetation of Calligonum, Salsola, Tamarix, and other xerophytes; the arboreous Salsola is particularly interesting. The photographs of Java, forming the third part, have been supplied by Prof. M. Büsgen, Mr. H. Jensen, and Dr. W. Busse. The subjects chosen include the teak forests, an expanse of the lotus, *Nelumbium speciosum*, a sand-dune bound by the creeping *Spinifex squarrosus*, and a bamboo forest.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Remarkable Coelenterata from the West Coast of Ireland.

I have been allowed to examine a small collection of Alcyonaria and Antipatharia that has been obtained by the fisheries branch of the Department of Agriculture for Ireland from deep water off the west coast of Ireland, and as this reveals some features of special interest I should be glad of an opportunity to write a short preliminary note upon it pending the examination of the species in detail.

The most interesting feature, perhaps, is the Coralliid, *Pleurocorallium johnsoni*, from 382 fathoms, about sixty miles off Achill Island. The family of precious corals to which this species belongs has hitherto only been obtained in the Mediterranean Sea, the Japanese seas, off Madeira and the Cape Verde islands, and in the Banda Sea. The specimens obtained by the *Challenger* in the Banda Sea were "dead," but I have recently published a preliminary note on a new species of precious coral from deep water off the coast of Timor, which was captured "alive" by the naturalists of the *Siboga* Expedition.

The distinction between the genus Corallium, to which *C. nobile*, the precious coral of the Mediterranean, *C. japonicum*, and *C. reginae*, the new species from Timor, belong, and the genus Pleurocorallium is not a distinction of very great importance, and, as recently pointed out by Kishinouye, cannot, with convenience, be much longer maintained. If, however, for the present we retain the two generic names it must be noted that Corallium no longer maintains its monopoly of corals that are precious, as the species *Pleurocorallium elatius* yields some of the most valuable classes of coral obtained in the Japanese fishery. Both in Japanese waters and off the Cape Verde Islands the valuable and the commercially worthless Coralliidæ occur in the same fishing area, and consequently it would not be a matter for surprise if a renewed investigation of the locality from which the Irish Fishery Department obtained its specimen of *Pleurocorallium johnsoni* yielded some specimens of commercial value.

I should not like to suggest the prospect of a coral fishery off the coast of Ireland, as the sea is too stormy and the water too deep at the station from which the specimen came to render any such fishery commercially successful, but it would be a matter of considerable scientific interest to find that precious corals are growing within a few miles of our British coasts.

The second feature of interest is the occurrence in these waters of at least three species of Antipatharia. This group of Cœlenterata is one which I thought was entirely exotic. I can find no mention of any Antipatharians in any of the lists of the British marine fauna that I have examined, but perhaps some of your readers could inform me if I have overlooked any references to them. The species are, I believe, *Cirrhipathes spiralis*, *Antipathella gracilis*, and a species which I think must be new, but is allied to *Stichopathes lütkeni* in some respects.

Among the other interesting things in the collection are representatives of the alcyonarian genera Ceratoisis, Stachyodes, and Eunephthya, which I believe are new to the British fauna. The two pennatulid genera Kophobelemnon and Umbellula were obtained in deep water off the west coast of Scotland by the *Knight Errant* (Kophobelemnon only) in 1880, and by the *Triton* in 1882. These also have now been found off the west coast of Ireland. Although these genera may now be included in the British fauna as being found within the British area as defined by the British Association committee of 1888, they really represent the fauna that is common to the "mud line" of Murray of the eastern side of the North Atlantic Ocean.

Thus Pleurocorallium occurs off the Cape Verde Islands, Stachyodes off the Azores, *Ceratoisis grayii* off the coast of Portugal, *Antipathella gracilis* off the coast of Madeira, Kophobelemnon and Umbellula off the west coast of Scotland. These genera, with many others that live with them, constitute a fauna which is quite distinct from the ordinary shallow-water fauna of the British area.

Action of Radium on Gelatin Media.

Some misapprehension appears to exist in certain quarters as to the precise nature of the bodies I have called radiobes, as distinct from such aggregations as those which M. Dubois has obtained by the action of the salts of barium, radium, and manganese upon bouillon. M. Dubois describes his bodies as "*grosses vacuolides*," and their appearance is quite different from that of the bodies I have described, judging by the drawings which have been reproduced in the *Revue des Idées* during the last few months.

I have observed two distinct types of bodies, of an entirely different order of magnitude, one type, radiobes, extremely minute and only visible with the highest powers: the other visible with an ordinary magnifying glass. The latter are decidedly crystalline in their structure, and resemble the bodies obtained in various ways by the action of salts on gelatin. They are like the ones described by Schenck, and very like those obtained by Dubois and others.

The smaller type cannot be said to be large in any sense of the word, and are like the minutest visible diplococci or biscuit-shaped cocci. They do not exceed this size to any great extent.

It is therefore desirable that the two types should not be identified, as their appearance, order of magnitude, structure and behaviour seem to be quite different.

M. Dubois has not noticed these, and therefore it seems to me that his claim to priority is quite irrelevant.

Cambridge, October 21. John Butler Burke.

Border occasionally seen between Light and Dark Regions on Photographic Prints.

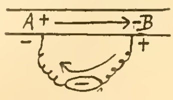
I have once or twice been asked why photographs are apt to show a line or band or edging along the boundary of a bright and dark region. My assistant, Mr. E. E. Robinson, has thought of the reason, and it may be convenient to publish it. In a developed film the exposed portion perceptibly differs in thickness from the unacted-on portion, and accordingly the linear boundary of two contrasted regions may sometimes act as a cylindrical lens, and during printing either concentrate or disperse the light on the positive immediately beneath it.

October 20. Oliver Lodge.

Terminology in Electro-physiology.

I would deem it a favour to be assigned the space of a letter in order to make a suggestion in connection with the above still vexed subject.

It cannot be said that even now all is peace in the realm of electrical terminology as applied to physiological phenomena, in spite of Dr. Waller's helpful efforts in this direction. Dr. Waller's term "zincative" admirably expresses that a given region (A) of excited tissue is "electromotive like the zinc of a voltaic couple,"[1] is, in fact, a source of current towards a region (B) of less excited or non-excited tissue (the current, of course, travelling in the tissue from the region A to the region B, and in the external circuit from the region B to the region A); but it leaves untouched the solution of the old muddle over the use of the signs + and −.



Confessedly, "zincative" avoids any reference to + and −, but every teacher of physiology knows that sooner or later the + and − must appear, and with them all the ambiguities of "negativity of action," &c., if the student is to make his notes "agree" with his text-book.

[1] "The Signs of Life from their Electrical Aspect," p. 17. (Murray, 1903

A large part of the difficulty arises from the different points of view taken by the electrician and the physiologist respectively, the electrician being concerned chiefly with the surfaces of conductors, the physiologist being interested chiefly in the interiors of living tissues.

Thus the above expression, "region A," is electrically ambiguous, for it may mean (1) either the *surface* of the region A, or (2) the *interior* of the same: certainly physiologically (and it may be also electrically) these are two very different things.

Are we speaking of surfaces or interiors when we talk of tissues and their electromotive states? This seems to me the gist of the initial obscurity.

In Dr. Waller's terminology A is "zincative" to B; but the electrically-minded student wishes to distribute his + and − somehow. The electrician says A is "negative" to B, because he is thinking of the surface at A to which current has been coming from B, as he finds by the galvanometer; but the physiologist, conceiving of what is going on *inside* the excited portion of tissue A, says, or should say, "A is electropositive to B," because he finds that current in the tissue must have come from A to B. The ambiguity is bound up with not distinguishing the surface from the interior.

All doubt, it seems to me, is removed when we say, the region A is, as to its interior, electropositive to B, but as to its surface electronegative to B; as to its *interior*, A is a "*positive plate*," as to its *surface* a "negative pole." Both these ideas are necessarily connoted by "zincative," only implicitly, however; for teaching purposes they must be made also explicit.

"Negativity of action" is then intelligible when it is distinctly laid down that it is only the *surface* of the active region that is being considered, for if the interior of the active tissue is thought of, then positivity of action must be the term descriptive of the electrical state.

If, then, the qualifying term "internally" or "externally," as the case requires, be added, no loophole for confusion is left; thus, A is internally electropositive to B, externally electronegative to B; B is internally electronegative to A, externally electropositive to A; for "externally," "galvanometrically" may be used.

Personally I think the use of the term "negativity of action" is, especially if used in teaching, objectionable, because misleading and mysterious; "internal positivity of action" certainly seems to describe a real state; as terms, the one is but the converse of the other. I have, however, no more sympathy with those people who persist in finding "negativity of action" entirely meaningless than I have with those who will not understand "negative pressure" or negative quantities of any kind.

DAVID FRASER HARRIS.

Physiological Department, University, St. Andrews, October 31.

The Engineer's Unit of Force.

IN a review of some recent works on mechanics in your issue of October 19, the reviewer calls to account two of the authors whose books are reviewed for "implying that the unit of force in the engineer's system is a variable quantity."

Perhaps there may be others than the authors referred to and myself who would welcome more explicit enlightenment on the subject of the constancy of the engineer's unit of force.

D. J. CARNEGIE.

October 23.

THE engineer's unit of force is equal to the earth's present attraction on the standard pound mass at a specified place, viz., for this country, *London*. Its magnitude is such that it produces unit acceleration when acting on a mass of 32·182 . . lb., the engineer's unit of mass, sometimes called a slugg (sluggish). The formula $M = W/g$, where M is the mass in sluggs, is true for any latitude, g being the acceleration of gravity there, and W the weight of the mass in pounds force, as would, for instance, be registered at the place by a massless spring balance which had been graduated in London. If the pound-poundal system of units is an absolute dynamical one, so also is the pound-slugg or engineer's system.

THE REVIEWER.

PROF. LANKESTER'S "EXTINCT ANIMALS."[1]

THOSE who, like the writer, had the good fortune to be present at the Royal Institution last Christmas and listened to Prof. Lankester's course of holiday lectures to young people will recall the fact that, although a goodly space was occupied by boys and girls from school, the theatre was elsewhere crammed with "grown-ups," who were quite as much interested and amused as the juvenile audience for whom these discourses were really designed.

It is, in fact, an open secret that quite elderly young people, as much as schoolboys and girls, enjoy their "ologies" when given to them in a form easy of digestion and with as few hard words as possible.

Before the memory of those pleasant afternoon discourses has faded from our minds comes a reprint of them in book form, with reproductions of more than 200 of the illustrations given in the text as we saw them on the screen.

Every boy and girl who heard those lectures will wish for a copy of this charming book, and those who did not will now read with delight the pictured story of extinct animals for themselves; nor will the "old boys" fail to take it up also.

Prof. Lankester explains that extinct animals are those which no longer exist in a living state. Animals, of course, die daily, and men too, but the lecturer tells us of extinct *kinds* of animals which no longer exist on the surface of the globe in a living state, although once they flourished and held their own.

He then informs his young friends of his own early experiences as a boy in visiting the British Museum and being fascinated by the huge head of an Ichthyosaurus from Lyme Regis with its large and bony-plated eyes, and its jaws, more than 3 feet in length, armed with powerful teeth.

Then the huge ground-sloth from South America attracted his wonder and admiration by its vast bulk, and he learnt that living upon the leaves of trees, but being too heavy to climb, it stood on the ground and pulled the trees down to it in order to feed on the young branches.

Their remains, often with the bones of the same individual lying in one spot, occur in the vast "pampas formation" and in the alluvial mud of the great rivers such as the La Plata. Here, too, one meets with the giant armadillo, and another strange creature, called the Toxodon, like a huge guinea-pig, nearly as big as a rhinoceros, with tremendous chisel-like teeth in front.

Prof. Lankester shows the thigh-bone of a giant reptile from North America more than 6 feet long (known as Atlantosaurus). What the size of the entire animal must have been we can best judge by paying a visit to the Cromwell Road Museum to see the skeleton of the Diplodocus lately set up there, which is 80 feet long and fully 14 feet high!

Passing rapidly over such forms as the ancient rhinoceros, the northern hippopotamus, the beaver, and great auk once common in Britain, but now extinct—the author tells how zebras, quaggas, antelopes, and giraffes are being fast killed off in Africa by our sportsmen, whilst the dodo and "Steller's sea-cow" were eaten up long ago, like the giant tortoises, by our early voyagers, who victualled their ships with these rare animals.

The author next explains the causes which have brought about the migration of some animals and the extinction of others, and how changes of climate and

[1] "Extinct Animals." By E. Ray Lankester, M.A., LL.D., F.R.S. Pp. xxiv+332; with 218 illustrations. (London: Archibald Constable and Co., Ltd., 1905.) Price 7s. 6d. net.

alterations of coast-lines have modified the existing lands so much that, as in our own islands, Great Britain and Ireland were, at no remote geological time, joined to France, and a continental, instead of an insular, climate prevailed here, with hotter summers and colder winters, suited to the mammoth and reindeer which roved quite freely from land to land.

FIG. 1.—A drawing showing the probable appearance in life of Arsinoitherium (original); from the Upper Eocene of the Fayûm, Egypt. From Lankester's "Extinct Animals."

He explains what "fossils" are, and how the sedimentary deposits, in which extinct organisms occur, have been gradually laid down on the sea-floor or along coast-lines. From minor changes he illustrates those greater ones which took place long since involving whole continents, so that where London now is was formerly the sea with marine shells and fishes, aptly reminding one of Lord Tennyson's lines:—

"Oh Earth! what changes hast thou seen—
There where the great street roars
Was once the stillness of the central sea."

The story of the living and extinct elephants is well told, and we get the latest evidence of the progenitors of these very ancient prehistoric beasts, the result of Dr. Andrews's explorations and discoveries in the Fayûm, Egypt, which has carried their ancestry back to the Eocene Palæomastodon and Meritherium. Near to the elephants comes the wonderful Arsinöitherium, also from the Fayûm, with a pair of prodigious horns on the front of its skull, a form of animal which may possibly have had a short proboscis like the tapir (Fig. 1).

The birds and reptiles come in for due share of attention, and from their striking forms they add largely to the attractiveness of the illustrations. The comparison of the wings of Pterodactyle, bird and bat is most instructive, showing that reptiles, as well as mammals and birds, enjoyed the power of flight, as some also equally possess the power of swimming. Dimetrodon was undoubtedly a swimming reptile (see Fig. 2).

Fishes, Mollusca, scorpions and Crustacea, also "sea-lilies," are dealt with in these lectures, and, as might naturally be expected, these simpler forms of life made their appearance far earlier in geological times than the more highly organised creatures now living on our earth.

More surprising still is it to find that the marine king-crabs (Limulus) and the scorpions (the latter at first aquatic, and afterwards terrestrial air-breathers) which are met with in the Upper Silurian rocks in America, Scotland, and Sweden have survived all the Old World changes of land and sea, the king-crabs being still found living in the China and Indian seas and on the east coast of North America, and the scorpions have spread over the *dry lands* of North and South America, Africa, and other countries, and are so little changed in appearance—whole generations of other animals having appeared and disappeared entirely—that we might almost imagine they would go on for ever!

Although it would be quite impossible for the author or anyone else to describe so vast a number of groups of living and extinct organisms in one series of lectures and afterwards to present them in book form with more than 200 illustrations in a single volume of 350 pages, at least Prof. Lankester knows how to give, in an attractive form, a vast amount of information agreeably, and to excite the interest of the merest tyro (whether young or old) and awaken a desire in him or her to learn more. Fortunately the author is also director of the Natural History Museum, where he has abundant opportunities to add still more to our personal knowledge of extinct animals.

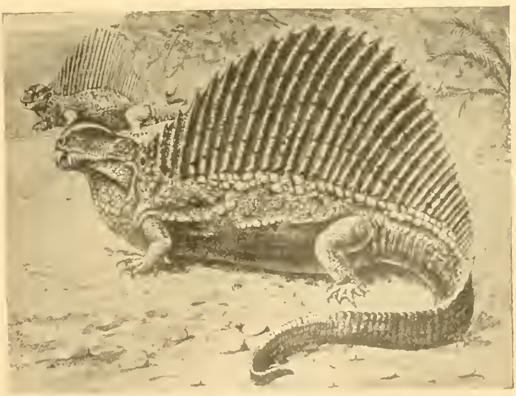


FIG. 2.—Probable appearance in life of the Theromorph Reptile, Dimetrodon, from the Permian of Texas. As big as a large dog. (It had a huge back-fin, evidently fitted for aquatic progression.) From Lankester's "Extinct Animals."

We give the book a hearty welcome, feeling sure that its perusal will draw many young recruits to the army of naturalists and many readers to its pages.

ASTRONOMY AND METEOROLOGY IN AUSTRALIA.

A VERY important paper has been issued recently by the Government printer of Adelaide, South Australia.[1] It is a report of an Inter-State Astronomical and Meteorological Conference, convened in May last, in view of the possible transfer of the observatory departments to the Federal Government as provided for in the Commonwealth Constitution Act. The official directors of the observatory departments of the several States were invited, and there were present Sir Charles Todd, K.C.M.G., F.R.S. (Government astronomer for South Australia), who was called to the chair, Mr. H. A. Lenehan (acting Government astronomer for New South Wales), Mr. W. E. Cooke (Government astronomer for Western Australia), Mr. P. Baracchi (Government astronomer for Victoria), Mr. A. A. Spowers (chief surveyor for Queensland), and Mr. H. C. Kingsmill (Government meteorologist for Tasmania).

The report represents briefly, in the first place, the present arrangements for public astronomical and meteorological work in the several colonies and the provision for weather telegrams. It then proceeds to give its proposals for the future in twenty-two resolutions. Six of them refer to work in astronomy, magnetism, or seismology; the remaining sixteen indicate a scheme of organisation of the meteorological service of the Commonwealth. The scheme is framed on the idea of the establishment of a central federal institution for theoretical and scientific meteorology, "where the observations for the whole of Australia should be collected, discussed and published, and where all the higher problems of meteorological science may be investigated; but such institution should have nothing to do with the daily weather service and issue of forecasts." Duties connected with the latter services, according to the scheme, are to be entrusted to an official in each State; and to the regulation of those services and their relation to the telegraph service the greater number of the twenty-two recommendations are devoted.

Appendices give the separate views of Mr. Baracchi, Mr. Cooke, and Mr. Kingsmill upon some of the recommendations.

The really important matter is the proposal for a separate establishment for the discussion of meteorological observations for the whole Commonwealth. The idea will be warmly welcomed by all those who desire to see the multitudes of meteorological observations brought into the most effective relation with practical life. That such an institution should have "nothing to do with the daily weather service and issue of forecasts" should probably be understood in an administrative sense. The ultimate effect of a scientific establishment upon forecasting would be a good deal more than nothing.

The calling together of the Inter-State Conference for the business-like discussion of the organisation of astronomical and meteorological work will also be warmly applauded in this country. It is one more expression of the fact that work in astronomy and meteorology is of more than local interest and importance. While doubtless real progress in either must still depend upon individual energy and individual genius, exchange of material has become a recognised necessity, and exchange of ideas an indispensable assistance.

It is therefore a pleasant duty to chronicle the appearance of this most promising scheme, which will put the Australian Commonwealth in a position to continue the excellent work of Russell and take its share in tracing out the mysteries of the meteorology of the Indian Ocean. When we remember the powerful appeal of Sir J. Eliot at Cambridge for the cooperation of the British dominions in working out meteorological problems of the widest application the solution of which is foreshadowed by the suggestions of relationship between meteorological phenomena in different parts of the world and of their connection with solar changes, we can only hope that this proposal for the federation of Australia for scientific prosecution of meteorological work is a step in the direction of a wider federation for a similar purpose.

On this planet, north and south and east and west are not so far apart that we in this country or our comrades in America or Africa can affect to regard the meteorological organisation of Australia as a question which does not concern us, and we shall watch the development of the scheme which is put forward, confident in its power of contributing in large measure to the pursuit of a common purpose in an organised manner.

W. N. S.

FERDINAND BARON VON RICHTHOFEN.

THE unlooked-for death of this distinguished man of science has sent a thrill of deep regret all over the world among those who take interest in the progress of geology and geography. Though he had passed the limit of three-score years and ten, he remained up to the last so active in mind and body, so full of an almost youthful interest in the advances of science, so keenly solicitous and enthusiastic over the welfare of the institutions with which he was connected, that all who knew him looked forward to still many years during which his inspiration and guidance would continue to be at the service of those departments of investigation which have long been so deeply indebted to him; but this augury proved vain. While sitting at his writing table, apparently in his ordinary health, a sudden seizure deprived him of speech. Yet, as he remained otherwise fully conscious, it was hoped that the symptoms might soon pass away. A little later, however, another seizure attacked him during a deep sleep, and after two days and a half he passed peacefully away on October 6, without illness or suffering of any kind.

Belonging to a noble family that possesses large estates in Silesia, Richthofen was born there on May 5, 1833. His early education was received at a seminary under the management of Roman Catholic ecclesiastics, from which he passed to the University of Breslau and then to that of Berlin, where he took his degree of Doctor in Philosophy in 1856. By this time a study of the writings of Leopold von Buch and Alexander von Humboldt had kindled in him a vivid appreciation of the attractions of geological and geographical research. Like the two great masters from whom he drew his inspiration, he appears to have begun his career as an author by publishing some of the results of his investigation of eruptive rocks. His earliest papers, which began in 1856, dealt with the intrusive melaphyres of Moravia and the trachytes of Hungary.

Repairing to Vienna, he made the acquaintance of the geologists of that capital, and notably of the eminent director of the Austrian Geological Survey, Ritter von Hauer, with whom he formed a lasting friendship. He was induced to become a volunteer in this survey and to assist in working out the complicated structure of parts of the eastern Alps. He spent two busy seasons among the Dolomite Mountains, which in after years he looked back upon as one of the happiest periods of his life. The results of these field-surveys were embodied by him in his

essay on the Dolomite region, which was a remarkable production for so young a man.

In the midst of his Alpine work he was offered a post as geologist on a Prussian expedition to Japan, China, Siam, and the adjacent regions. The opportunity of foreign travel and exploration was too tempting to be resisted. Quitting his Austrian labours he sailed for the East, and during the next two or three years, from 1860 onwards, contributed to the scientific journals various papers descriptive of some of the tracts which he visited. Owing to circumstances which prevented him at the time from undertaking exploration in the heart of Asia, he crossed the Pacific and spent several years in western North America, where he specially devoted himself to a detailed study of the igneous rocks of that marvellously volcanic region. It was there that he prepared his now classic memoir on the "Principles of the Natural System of Volcanic Rocks," which was published in English among the memoirs of the California Academy of Sciences. This sojourn in America enabled him, moreover, to obtain a mastery of the English language, such as few foreign men of science could equal.

The opportunity of returning to Asia came at last in the autumn of the year 1868, and he eagerly availed himself of it. He spent some years in travelling over most of the provinces of the vast empire of China, studying their physical features and geological structure, and forming an extensive collection of their rocks and fossils. So voluminous were the data which he gathered together that they filled a series of massive volumes, of which the first appeared in 1877, and the Atlas in 1885. This work placed him in the front rank of scientific pioneers. It not merely made known for the first time the physical geography and geology of a vast territory, but presented contributions of great value towards the elucidation of disputed problems in science.

Richthofen's reputation as a travelled and accomplished geographer had now spread so widely that in the year 1875 he was offered, and accepted, the chair of geography in the University of Bonn, where he spent eight happy and fruitful years, and where he married the accomplished lady to whom he had been long attached. From Bonn he was called to occupy a similar position at Leipzig, whence, after only three years, he was invited to become professor of geography in the University of Berlin. In the metropolis of the German Empire he found ample scope for his rare faculties of exposition and organisation. Besides the ordinary duties of his professorship, he instituted meetings of various kinds for promoting the cultivation of geographical and geological studies, and amassed a wonderful collection of books, maps, instruments, models, and other illustrations of the physical features of the earth's surface. His enthusiasm in these efforts was rewarded three years ago by his appointment as director of the new geographical institute in Berlin, where he had ample space to arrange and display the remarkable mass of material which he had gathered together with the view of bringing home to the mind and eye the characteristic aspects of land and sea and the history of exploration and discovery in oceanography.

Baron von Richthofen was a geographer of the highest type. To him the mere addition of so many hundred square miles of territory to what was already known of the earth's surface, and the opportunity of affixing the names of friends and benefactors to peaks and promontories and inlets, were matters of comparatively little moment. It was the grand features of land and sea that interested him, their origin, their history, their relations to each other, their influence on the progress and destiny of mankind. His early geological training eminently fitted him for investigating these problems on the ground, and kept him from making the mistakes which attention restricted to mere superficial features has so often produced. He possessed in rare measure the qualities which ensure the success of an explorer—health and strength, alike of body and mind, a wide range of natural knowledge, courage, patience, endurance, tact, and kindliness. It may have been the consciousness of the possession of these qualities, combined with a recollection of the pleasure which their exercise had given him in his varied wanderings in Europe, Asia, and America, that led him to write, in the midst of his university and other work, his admirable "Führer für Forschungsreisende," which was published in 1886. No one but a born and trained explorer, who had enjoyed ample experience by flood and fell, all over the globe, could have given to the world such a volume, so full of the ripest practical knowledge, so broad in its conception of what exploration should be, and so clear and emphatic in its statement of the accomplishments which are needed for the making of a successful traveller. Every department of observation is luminously presented in his chapters, which may be regarded as a contribution of the first importance to physical geography and geology. The volume is one which ought to be put into the hands of every man who proposes to undertake the examination of new or little known regions, and who is willing to learn beforehand what is expected of him by those most competent to judge.

With Berlin as his headquarters, and a home there which attracted men from all lands, the Baron and his gracious and devoted wife formed the centre of a large circle of friends; but he journeyed far to attend meetings and congresses, where his handsome presence and genial talk were always welcomed. Hence not many men of science of his day were more widely known personally than he. He received endless marks of appreciation from learned societies and academies, both in the Old and in the New World. Our own Royal Society honoured itself by including him in its list of foreign members. His death has left a blank in scientific society which no living man is competent to fill. For many a year he will be regretted by all who even only slightly knew him, and mourned by those who were privileged to enjoy his friendship.

A. G.

THE TREASURY AND MEN OF SCIENCE.

The subjoined letter from the Earl of Crawford appeared in Monday's *Times*. The parsimony of the Government in everything relating to the scientific work needed for the State service is well known; what is not yet known generally is how much the administration is weakened by the entire absence of science, and therefore of the scientific spirit, in the higher ranks of the Civil Service, and especially of the Treasury. The official action described by Lord Crawford is another indication of the inability of the official mind to understand that science has any place in the nation's activities.

To the Editor of the "Times."

Sir,—The death, noted by you to-day, of my dear friend and colleague Dr. Copeland, His Majesty's Astronomer for Scotland, creates a vacancy in the scientific staff of Great Britain.

Will you permit me, Sir, to offer a word of warning to any who may be asked to succeed him?

Students or masters of astronomy are not, in the

selfish sense, business men, nor are they as a general rule overburdened with this world's goods. It behoves them henceforth to take more care as to their future in case of illness or physical infirmity, and not to trust to the gratitude or generous impulse of the Treasury Department.

In old days it was the custom when a man distinguished in science was brought into a high position in the Civil Service that he was credited with a certain number of years' service ranking for pension. This practice has been done away with and a bargain system substituted. A short while ago the growing agonies of heart disease caused Dr. Copeland to feel that he was less able to carry on the duties of his post, and he determined to resign; but he learnt that under the scale, and in the absence of any special bargain, the pension he would receive would not suffice for the necessities of life. The only increase his friends were able to get from the Treasury was an offer to allow him about half-a-crown a week extra by way of a house.

Indignant and ashamed of my Government I persuaded Dr. Copeland to withdraw his resignation and to retain the official position which he has honoured till his death.

I trust, Sir, that this memorandum of mine may cause eminent men of science who are asked to enter the service of the State when already of middle age to take heed for their future welfare.

I am, Sir, your obedient servant,

CRAWFORD.

2 Cavendish Square, October 28.

The number of years *given by Act of Parliament* was twenty, because the ordinary civil servant joined at twenty to learn his work, and men of science joined at about forty because they had to learn it before they were of any use to a Government department.—[ED.]

THE BRITISH SCIENCE GUILD.

THE inaugural meeting of the British Science Guild, the organisation and objects of which were stated in NATURE of October 12 (vol. lxxii. p. 585), was held at the Mansion House on Monday, October 30. The Lord Mayor presided. Among those who had accepted the Lord Mayor's invitation to attend were the following:—

The Bishop of Ripon, Lord Strathcona, Mr. Haldane, K.C., M.P., Sir Norman Lockyer, Lady Lockyer, Sir Michael Foster, Sir William Ramsay, Lady Ramsay, Sir J. F. Maurice, Sir J. Wolfe-Barry, Sir W. Bousfield, Sir G. T. C. Bartley, Sir E. W. Brabrook, Sir C. Bridge, Sir Lauder Brunton, Sir A. Geikie, Sir W. Mather, Sir H. T. Wood, Dr. G. T. Beilby, Dr. Caird, Captain Creak, Dr. Ferrier, Dr. W. Garnett (represented by his son), Mr. Gifford, Dr. Glazebrook, Prof. Gowland, Mr. R. A. Hadfield, Prof. J. Larmor, Prof. Lealey, Dr. Lockyer, Mr. C. W. Macara, Prof. Meldola, Prof. Perry, Mr. J. H. Reynolds, Dr. Shaw, Mr. A. Siemens, Mr. Swinburne, Rev. T. R. Stebbing, Mr. Carmichael Thomas, Prof. S. P. Thompson.

The following are extracts from letters expressing regret at inability to attend the meeting.

Mr. Chamberlain:—

"I am very sorry to find that I cannot possibly be in London on Monday the 30th inst. . . . I very much regret that I cannot take an active part in the meeting on this occasion, but possibly some more convenient opportunity for showing my interest may occur at a later time."

Lord Roberts:

"I am very sorry to refuse the request contained in your letter of the 12th instant, but I have so much on hand at present that I could not manage to attend. . . . I recognise the value of the Guild and wish I could help it."

Lord Rayleigh:—

"I fear I shall not be able to come to the meeting . . . but I shall be very pleased to join in the movement and become a vice-president if desired."

The following report of the meeting is reproduced, in great part, from Tuesday's *Times*:—

The Lord Mayor in a few words welcomed those who had accepted invitations to be present, and called upon Sir Norman Lockyer to read the report of the organising committee.

Sir Norman Lockyer, having read the report, said that the organising committee was grateful for the consent the Lord Mayor so readily accorded to them to hold their first meeting at the Mansion House. He had every hope that under such auspices the guild might do for British national endeavour in the future what so many ancient guilds, each in its special line of action, were founded to do in the long past. When his own views as to the importance, nay the burning necessity, of such a movement as that throughout the land, among all classes, and in touch with all employments, were expressed some time ago, he suggested that it might be brought about by extending the functions of some existing organisation, such, for instance, as the British Association; but he was soon made to see that that was to take a too narrow view of the matter. It was not a question merely of science and scientific men; it was a question of conducting all our national activ'ties, State service, private service, and what not, under the best possible conditions with the greatest amount of brain-power. To show that it was not a question only for scientific men, he would just refer for a moment to the matter of education. He yielded to none in respect for those studies which embraced ancient civilisations and their literatures, but they alone were as incapable of forming the complete man as would be instruction in the mere facts of science apart from the actual use of the methods of observation and discovery. A complete education must be based upon things and thinking, as well as upon words and memory. We wanted one kind of education for everybody—the best. We wanted that education carried as far as possible in the case of each individual, whether the time for education was long or short. No one should be stopped, save by his own incapacity, from proceeding further down the fair stream of education which should make the complete man, both educationally and physically. We want that stream freed from the impediments with which it was at present dammed—they might spell the word as they liked. These impediments were many of them needlessly hurtful, and most of them unnecessary from a large point of view.

Indeed, they wanted to revert to the ideal of the ancient university, from the curriculum of which *natura rerum* was never absent, and in which the poor student was always cared for. The western world was wondering at the efficiency of both the navy and the army of Japan. There was really nothing to wonder at. Most of the reasons suggested for what had happened were, he held, entirely wrong. If the Japanese religion or the old Japanese civilisation had been in question, then China would have followed suit. What really had happened in Japan was that for the last thirty years everybody, from the Mikado to the smallest boy and girl, had been taught to think. They had been dealing with things as well as words in their schools, and they represented at the present moment the *maximum* of efficiency and brain-power as the result of that treatment. Mr. Chamberlain, Lord Rosebery, and others had referred to the great relative advance of the commerce and industry of Germany and the United States. He would again point out that these were examples of lands with complete and numerous State-aided universities. Surely it was more than a coincidence when we found in those lands the State service and all the national activities carried on in the full light of modern science by men who had received a complete training. If the guild helped us in any way to improve our national position in this respect it would not have been founded in vain, but there was certainly much for it to do along many lines.

The Bishop of Ripon moved the first resolution:—

"That the Right Hon. R. B. Haldane be elected president of the British Science Guild." He said they had met together to enforce as far as they could what had fallen from Sir Norman Lockyer's lips. He supposed that all of them who had reflected would realise that the time had come in which it was desirable that an organisation specifically directed to that end should take its place among the useful institutions and associations of this country. He was quite sure that those who had thought hitherto of the somewhat aimless way in which the benevolent had gone about their work and the somewhat haphazard way in which, indeed, some of the industrious had pursued theirs, must realise that those ways were not likely to conduce to the general welfare, or even to conduce to the very object which the benevolent and the industrious had in view. He knew there were some who still looked askance at the words science and scientific method, and they had a sort of dim idea that science and scientific methods had come to destroy some of the most beautiful instincts of our nature. They were inclined to say to people that the new fangled notions had come in to incommode them in their activities, to destroy their cherished notions, and to check their benevolent intentions. But that was to misunderstand, as he took it, the whole situation. No person, however devoted he might be to the cause of science and scientific method, believed for a moment that science would be able to create faith or to create charity. They might, however, do a great deal to give confidence to faith, and certainly might guide the feet of charity into the ways and methods of wisdom. The value of applying science and scientific methods to all forms of human endeavour lay in the simple fact that there was the educating power which charity and benevolent impulse so generally and so legitimately desired. Everyone desired to help the needy; but who did not know that the methods of indiscriminate charity had really ended in defeating the ends which the charitable had in view? But the scientific study of economic conditions was capable of putting into the hands of the charitable the proper method of dealing with the needy. He could only recall to their minds what an eminent Frenchman said in speaking of France after the war. He said, speaking of his fellow-countrymen and of the subject which had occupied Sir Norman Lockyer's mind that day—namely, the subject of general and specific education from a national standpoint—that they had been defeated, not by Bismarck and Moltke alone, but by Kant and Hegel, Goethe and Schiller and Humboldt, and other great minds which Germany had produced. They had been defeated, in fact, he said, by the brain—the educated brain and the scientific method of those who contended against them. It was not the victory of arms alone, but the victory of brain brought to bear upon the field of war. He could imagine two classes of men becoming strongly and earnestly interested in this endeavour. He could understand the benevolent saying, "Teach us how to do good," and he could understand those who were interested in the prosperity of the nation saying, "Teach us how best to procure it." The benevolent mind was constantly brought into anxiety and suspense by questions of solicitude concerning the safety and the health of our fellow creatures, but here was a simple method by which science might come and say to the benevolent, "We are helping you to prepare the way." Let him direct their attention to two great institutions which existed, one in Holland and the other in Germany. There were two museums, called Museums of Safety, the purpose of which was to show in working models every appliance which had been devised by the care and the study of scientific men and experts for the protection of life and limb, for the promotion of health, for preventing the accident in the mine, the accident in the mill, the danger to health arising from noxious vapours in some of our great places of employment, and the accumulated dust which gets into the lungs of the worker. These and other important matters affecting the safety and the welfare of the people were dealt with in these museums. People were taught the best method of feeding their children by showing them what might be called the various values, the health values, of foodstuffs. They were shown also in economical fashion how a house might be built. These museums existed, and, with their working models, were open five days in the week for the inspection and instruction of the public. What were those great Museums of Safety which they found in Charlottenburg and Amsterdam but living witnesses of how scientific methods might be brought to bear on the protection of the health and life of the people of the world? Our manufacturers, and perhaps our farmers, had been content to go on in what might be called jogtrot ways, not watching how far knowledge had advanced beyond them, and the mere rule of thumb and the traditional methods had prevailed sometimes to the detriment of industry, often to that of the consumer. Those things were precisely the way in which that Science Guild might come forward and do what had been done in Germany, so that there might be places where the manufacturer and farmer might go and get scientific advice of the best character. Those were things which meant the one thing for which the guild had come into existence—namely, the application of scientific methods to human endeavours throughout the world. Precisely because the pressure of the competition of the world had become so great it was for us to say that the old England that we loved and were proud of should hold her place among the nations of the world, and as she had the courageous heart and the enthusiastic spirit so also she should be given the clear-thinking brain and the well-studied handicraft and industry. The urgency of the thing was clear, and the only way in which it could be applied was clear also. He concluded by proposing Mr. Haldane as president, and spoke of him as one who knew what was necessary for the public good, and essential for its industrial prosperity, and who added to that the weight of his name and the strong position which he held in the legal and political world.

Lord Strathcona seconded the motion. In doing so he said that it must be a great relief and satisfaction to all of them to find that they had placed before them something which savoured in no sense of party politics—an object which was for the general good.

Sir W. Mather supported the motion. He said that in this country we had the foundations for the highest scientific industry the world possessed. We had in many of our industries the most brilliant scientific methods and processes. We had plenty of science in England; we knew what the Germans knew, and what the Americans knew. The trouble was that the people of England had not been trained to enable them to use largely the methods of science and the principles of science which the people of other countries—not the select men, not the men specially gifted, not the men of genius only, but the men who had the conduct, even in subordinate positions, of some of the departments of scientific manufacture—possessed. The association had for one of its objects the promotion of scientific education throughout the Empire by encouraging the universities and other institutions, where the bounds of science were extended, or new applications of science were devised. What men like himself looked for in adopting scientific methods generally throughout their workshops was the foreman class, the subordinate managers, the managers who could carry out the advance of science which emanated from the top. He had just returned to England after four months' absence in the United States, and he found, while in America, that the whole tendency and trend of American thought and feeling was to take masses of their young men and train them, so that they might take their part not as managers, employers, capitalists, and so on, but as workers in their industries. That society had before it its greatest work in looking to the education of the people of England. It should work upon the Government of the day, Liberal or Conservative, and take care that there should be sufficient expenditure and sufficient convenience provided throughout the length and breadth of the land to enable our young people to have some opportunities in their lives like those which were afforded to the young people of the United States.

The resolution was carried unanimously.

Mr. Haldane, who was received with cheers, said he gratefully acknowledged that resolution and the honour which they had conferred upon him in electing him president of that new organisation. He did not know

that he had other qualifications for it than this—that the matter was one which interested him intensely. Nearly ten years ago, when the political party to which he belonged went out of office, he looked about for something to do, and he thought he might as well turn his hand to the somewhat cobwebbed state of the higher education of this country. After a time he approached the Government, and he found them sympathetic, and they had remained throughout that period sympathetic. There were those who said that some time or other they would go out and another Government come in. He hoped in the same way to have a chance of approaching that Government and trying to persuade it to be sympathetic. Why was it that so many people had come together that day—people of different minds but converging upon the same idea—to call for an activity which should be unhasting and unresting, the organisation of the higher science in its application to the affairs of this country? He thought it was because almost every year in an increasing fashion brought us in this nation an awakening. We were not the only nation which had received an awakening. Japan wakened up the nations of the West from their dogmatic slumber not long since, and we had perhaps not even yet assimilated the lesson which that awakening had taught the world. He agreed with Sir Norman Lockyer that that organisation ought not to mean merely science. It ought not to mean merely instruction; it ought to mean the bringing of method, the bringing of thinking, into the modes of government which applied to our public affairs and which applied to our private industries alike. That was what we wanted, and without that we should fall behind, and that kind of organisation meant science, and it meant education. The Bishop of Ripon alluded to the question of the Poor Law. There was a very interesting pamphlet which was published the other day, and which he commended to all of them who had not read it—the report of the Birmingham brass-workers on what they found when they went to Berlin to compare the condition of the working men of their own trade with that of similar working men in the German capital. One thing which they discovered was that in Germany the unemployed question had been to a great extent solved. There were two ways in which they could deal with the unemployed question without solving it. One was to do nothing at all, but say that so-called economic laws must work their way. That view, he thought, opinion nowadays condemned. But there was another way which he hoped the nation would condemn just as severely, and that was to grant public money in response to any demand which was made by ignorant people without recognising the fact that steps of that kind merely meant that one got a body of honest but weak people who came to depend, not on their own exertions, but on what the State would do for them. The brass-workers found organisation. They found that science had been set to work to solve the problem of the unemployed. They found that the unemployed were sifted out by State, municipal, and private charitable organisations directed and employed by the State. They were sifted into classes. Those who wanted work and could not get it were provided for to almost a complete extent by the cooperation of the Government and the employers and the municipalities. Those who had not got work and did not want it were put into places which were not prisons, but where they were forced to work for a very moderate wage, which was saved up for them and given to them afterwards. The Birmingham brass-workers came back with the view that the provision for the German brass-worker was superior to anything even in Birmingham. They were too enthusiastic. He had lived in Germany, and he knew that the things they saw there would never be tolerated in this country. From the cradle to the grave the German was ruled. Paternal government was exercised over him, well aided by what he might, figuratively speaking, call the birch rod. At no point of his existence was he a free man, and the result was that in Germany to-day there was something like a revolt, and an aspiration for our British freedom. A pamphlet had been published on the Germans and their Fatherland, in which a plea was put forward for the study and imitation of English institutions. It had had an immense circulation in Germany, and ought to be translated into English. The writer advised his readers to go to see Eton and Harrow, where there might not be much learning, but where the boys ruled the school, set up public opinion among themselves, and as a result turned out governors of men and patriots, instead of men who, like the Germans, when they left their country felt in the recollection of their schools that they had left an almost prison life. That great German authority was under the same delusion as the Birmingham brass-workers. He was too enthusiastic. But in that pamphlet the German Emperor was quoted as making the observation that the real truth about the matter lay between the German and the British systems. We had to see how we could get the German faculty of organisation, train people to think more of it, and apply it to the various departments of our affairs. Our executive Government was about as disorganised an institution as anybody could conceive. Suppose they wanted to appoint a man of high scientific mind as an official. They were at once told that it would be against the rules of the department. In vain they would reply they were bringing in a man of science for public purposes; the answer would be that the Civil Service rules made it difficult to do anything of the kind. Some of them had been trying to impress upon the nation that the organisation of the highest education of the universities ought not to be left to haphazard. He was chairman of a committee which sat last year, and they made a report which had been more lucky than most reports. One of its recommendations related to the grants to the university colleges of this country, and was that a scientific advisory body should be created and put at the elbow of the Treasury to advise it in giving money to the universities. He was glad to say that a sympathetic Chancellor of the Exchequer had adopted that suggestion, and in the course of the winter they would learn who the advisory members were to be. Let them take another department —the Board of Trade. The Board of Trade ought to be a great ministry of commerce. We had a vast home trade as well as a vast foreign trade, and the statistics relating to them should be of the most authoritative kind. There was the same necessity for scientific methods in relation to the Home Office and the departments with which it dealt. For himself he believed that things would not be right until we had a scientific corps under a permanent committee, just as the Defence Committee was under the Prime Minister to-day. He meant a body that would not consist merely of officials of the ordinary kind, but should consist of the most eminent men of science, who would go there because they were honoured and put on the footing upon which they deserved to be placed, and were recognised as a body of men who would be at the elbow of the department, and could organise the scientific work of the State. He hoped that if they got to that, the example of a Government adopting science would be followed by the municipalities, as he believed it was going to be followed more and more by our manufacturers. There was great work for that association to do. We lived in a country where science was not so much appreciated as it should be. Our people liked to see cash over the counter, and they did not like to wait for deferred payment. But we were waking up, and we had this enormous advantage, that our very individualism had produced some of the finest scientific talent of the world. He did not like to mention men on that platform, though he could do so, whose names ranked with the highest of the world. We had produced, to speak of those who were absent, our Kelvins, our Rayleighs, our J. J. Thomsons, than whom the world had no greater, to say the least of it. He had no doubt that if the British nation were given a chance it could beat the world. But we wanted knowledge. This was a new century; we had a new Sovereign; we might have a new Parliament; we should have a new chance. Let us see to it that we used our opportunities. The midnight call had come, let us take heed that we were ready. Knowledge was power. That was the great lesson of to-day. Let us hold to it that knowledge was power, and that without knowledge there was no real power in these times of intense competition.

Mr. C. W. Macara (president of the Federation of Master Cotton Spinners' Associations) moved:—"That

those whose names are given in the provisional list as vice-presidents and officers of the British Science Guild be elected in those capacities and asked to serve."

This list is as follows:—

Vice-presidents: The Right Hon. the Lord Mayor of London, Sir Lawrence Alma-Tadema, O.M., R.A., the Right Hon. Lord Alverstone, G.C.M.G., F.R.S., Lord Balcarres, M.P., the Right Hon. the Earl of Berkeley, Admiral Sir Cyprian Bridge, G.C.B., Sir William Broadbent, Bart., K.C.V.O., F.R.S., Sir Walter Buller, K.C.M.G., F.R.S., Sir J. Burdon-Sanderson, Bart., F.R.S., Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., the Right Hon. Joseph Chamberlain, M.P., F.R.S., Sir William Church, Bart., K.C.B., Sir George Sydenham Clarke, K.C.M.G., F.R.S., Sir John Colomb, K.C.M.G., M.P., the Right Hon. the Earl of Donoughmore, the Right Hon. Earl Egerton of Tatton, Sir John Eliot, K.C.I.E., F.R.S., Sir Michael Foster, K.C.B., M.P., F.R.S., the Right Hon. Sir Edward Fry, F.R.S., Sir Archibald Geikie, F.R.S., Mr. F. Du Cane Godman, F.R.S., the Right Hon. Sir John Gorst, K.C., M.P., F.R.S., the Right Hon. Lord Haliburton, G.C.B., Sir Joseph Hooker, G.C.S.I., F.R.S., Sir Alfred Jones, K.C.M.G., the Right Hon. Viscount Knutsford, G.C.M.G., Prof. Ray Lankester, F.R.S., Dr. J. Larmor, F.R.S., Mr. C. W. Macara (president of Federation of Master Cotton Spinners' Associations), Sir Charles McLaren, Bart., K.C., M.P., the Right Hon. Sir Horace Plunkett, K.C.V.O., F.R.S., the Right Hon. Lord Rayleigh, O.M., F.R.S., Prof. Rhys, the Lord Bishop of Ripon, Mr. E. Robertson, K.C., M.P., the Right Hon. Lord Tennyson, P.C., G.C.M.G., Sir Philip Watts, K.C.B., F.R.S., His Grace the Duke of Wellington, K.G., G.C.V.O., Sir John Wolfe-Barry, K.C.B., F.R.S.; *chairman of committees:* Sir Norman Lockyer, K.C.B., F.R.S.; *vice-chairmen:* Sir William Abney, K.C.B., F.R.S., Sir Lauder Brunton, F.R.S., the Right Hon. Sir John Cockburn, K.C.M.G., Sir Gilbert Parker, M.P.; *trustees:* the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., Sir Henry Roscoe, F.R.S.; *hon. treasurer:* the Right Hon. Lord Avebury, F.R.S.; *hon. assist. treasurer:* Lady Lockyer, 16 Penywern Road, S.W.; *hon. secretary:* Mr. C. Cuthbertson, *pro tem.*

Admiral Sir Cyprian Bridge seconded the motion. In doing so he said that the officers of the Japanese navy had frequently mentioned to him the satisfaction it was to them, and the benefit it had been to them, to have been brought up by officers of the British Navy.

The resolution was agreed to.

Sir J. Wolfe Barry moved:—"That the president, vice-presidents, and officers and the other members of the Guild mentioned in the provisional list be elected members of the general committee of the Guild." He said that the movement must be looked upon as an educational movement, to educate the people at large and the Government and political parties not to undervalue the great resources of science in the development of the kingdom. Much had been done, and he had only to look back on the progress of the nineteenth century to see how leading a part science had taken in the development of the nation. But everybody must admit that we must not rest and be thankful for what had been done. An immense amount remained. This country must not stand still. It had the most vigorous competitors, who brought all the product of science into the contest which they waged against us in so many industrial and social ways. The business of that guild would be, he thought, to urge everybody to go forward in hope, and we must not suffer ourselves to be left behind by the development of other nations from whom we might learn much. At the same time, he firmly believed that this country had nothing to fear if only it were true to itself.

Major-General Sir J. F. Maurice seconded the resolution, which was passed.

Sir W. Ramsay moved a vote of thanks to the Lord Mayor. In doing so he said that in England we had a great deal of scientific ability. Much of it was organised, but its application to the affairs of the State, to the Army, to the Navy, to the service of the nation at large, could be very much better organised than it was. The object of that guild was to attempt to effect that organisation, which was so much required. If that was so he was sure they would all agree that to promote the object of that guild was one of the most important tasks which the nation could undertake. He hoped they would all unite to promote that object and gain adherents for the guild, with the result that before many years we should be less of a disorganised rabble and more of an organised army than we were now.

Dr. Robert Caird seconded the motion, which was heartily carried.

NOTES.

We regret to announce that Prof. Ralph Copeland, Astronomer-Royal for Scotland and professor of astronomy in the University of Edinburgh, died on October 27, at sixty-eight years of age.

Captain F. W. Hutton, F.R.S., curator of the Canterbury Museum, Christchurch, New Zealand, and president of the New Zealand Institute, died on October 27 while returning home by the R.M.S. *Rimutaka* at the conclusion of a visit to England. He was sixty-eight years of age, and was elected a Fellow of the Royal Society in 1892.

An interesting gathering of the old pupils of Mr. Francis Darwin, F.R.S., formerly reader in botany, was held in the botany school of the University of Cambridge on October 28, when his portrait, by Mr. W. Rothenstein, was presented to the botanical department by a body of subscribers, all formerly his pupils. To Mr. Darwin himself was presented a handsome book containing autographs of his pupils. Speeches were made by members of the staff and by other botanists regretting the severance, after twenty-one years, of Mr. Darwin's connection with the botanical department.

At a meeting of the general committee of the British Association held on Tuesday, Leicester was adopted as the place of meeting of the association in 1907 by the following resolution, which was passed unanimously:—"That having regard to the fact that no meeting of the Association has as yet been held in Leicester, the general committee decides to accept the cordial invitation from that town, and at the same time expresses its most hearty appreciation of the kind and courteous invitation from the city of Dublin, and ventures to express the hope that the invitation may be renewed at an early date."

On Monday, October 30, a strong earthquake shock, lasting four seconds, was recorded at Catanzaro in the afternoon; and two earthquake shocks, one rather marked and the other slight, were observed at Monteleone in the evening.

We have received a letter from Dr. Faulds in which he replies to the review of his book on October 19 (supplement, p. iv). The more important part of his letter lies in the assertion that he *had* devised a method of classifying finger-prints. Where can an exact description of his method be found? His book contains only generalities about it, and his present letter goes no further.

At the annual general meeting of the Royal Society of Edinburgh, held on October 23, the following officers and members of council were elected:—*President,* the Right Hon. Lord Kelvin, G.C.V.O., F.R.S.; *vice-presidents,* Hon. Lord M'Laren, Prof. Flint, Dr. R. Munro, Sir John Murray, K.C.B., F.R.S., Dr. R. H. Traquair, F.R.S., Prof. Crum Brown, F.R.S.; *general secretary,* Prof. George Chrystal; *secretaries to ordinary meetings,*

Prof. D. J. Cunningham, F.R.S., Dr. C. G. Knott; *treasurer*, Mr. P. R. D. Maclagan; *curator of library and museum*, Dr. Alex. Buchan, F.R.S.; *councillors*, Prof. Andrew Gray, F.R.S., Dr. R. Kidston, F.R.S., Dr. D. Noël Paton, Prof. John Chiene, C.B., Prof. J. Graham Kerr, Dr. W. Peddie, Dr. L. Dobbin, Prof. J. C. Ewart, F.R.S., Dr. B. N. Peach, F.R.S., Dr. J. J. Dobbie, F.R.S., Prof. G. A. Gibson, Prof. J. P. Kuenen.

AN International Fisheries Exhibition, to include everything connected with the sea—either oceanographical or sea fisheries business—will be held at Marseilles under official control from April to October, 1906. The oceanographical part of the exhibition will illustrate the work of the principal biological societies, marine zoological laboratories, and similar institutions. The investigations of the Prince of Monaco will occupy a large room, and France, Germany, Portugal, the Netherlands, Norway, Sweden, America, Japan, and England will have separate spaces allotted to them. The practical and industrial side of fisheries in many parts of the world, as well as the products of the sea, will be represented. Applications for space will be received up to January 15, 1906, by the agents, Exposition de Marseille, 5 rue des Mathurins, Paris, who will also supply any further information required.

MAJOR-GENERAL SIR CHARLES WILSON, K.C.B., F.R.S., died on October 25 at Tunbridge Wells in his seventieth year. Trained as a soldier, his aptitude for work outside the routine of regimental duty soon led to his appointment in directions in which his scientific attainments could be utilised. In 1858, when he was but twenty-two years of age, he was appointed secretary to the North American Boundary Commission. From 1864–6 he was engaged on surveys of Jerusalem and Palestine, and for two years after this with the Ordnance Survey of Scotland, when he again left home to undertake the survey of Mount Sinai. This piece of work was followed by seven years as the director of the topographical department of the War Office. From 1876 to 1878 he was engaged on the Ordnance Survey of Ireland, and from 1886 to 1894 Sir Charles Wilson was the director-general of the Ordnance Surveys at headquarters. He was elected a Fellow of the Royal Society in 1874, and was twice president of the geographical section of the British Association, in 1874 at Belfast and in 1888 at Bath. He served as a vice-president of the Royal Geographical Society from 1897–1902. He was the author of several works on those countries in the east where his surveying work was done, in addition to one or two well known guide-books. It is interesting, in view of the attention given in recent years to the claims of geography to be included in the subjects required of army officers, to remember that Sir Charles Wilson, in his British Association address in 1874, spoke of the influence which the physical features of the earth's crust have on the course of military operations, and of the consequent importance of the study of physical geography to all those who have to plan or take part in a campaign.

A MEMORIAL bust of the late Dr. Joule was unveiled on October 28 at Sale, near Manchester. The ceremony was performed by Sir William Bailey, president of the Manchester Literary and Philosophical Society, who delivered an address. In the course of his remarks, Sir William Bailey said that Joule was born in New Bailey Street, Salford, in the year 1818. He studied under Dalton, who advised Joule's father to send him, on the completion of his studies, to Sturgeon, the inventor of the soft iron magnet. Under his instruction Joule became a competent electrician, and the inventor of electric welding. Mr. Denny Lane was at the British Association meeting at Cork in 1843 when Joule read his first paper on the "Mechanical Equivalent," and he assisted Dr. Joule to drum up an unwilling audience of six people, of which he was one. Sir William Bailey compared, in one part of his address, the coal consumption from the year 1840 to the present day. In 1840 the *Britannia*, 740 horse-power, Cunarder, used more than $4\frac{3}{4}$ lb. of coal, in 1862 the *Scotia* used $3\frac{1}{4}$ lb., in 1881 a steamboat used 2 lb., and to-day the lowest consumption is 1 lb. per horse-power per hour; much of this economy may fairly be credited to knowledge of the mechanical equivalent. There are about 13·500 British thermal units in a pound of good coal, and if there is no loss in consuming it there would be a power equal to five horses obtained from it; but engineers know that the best engines under the most scientific conditions and skilful attention with boilers under the most skilled superintendence only give a duty of 1 horse-power for 1 lb. of coal. Joule invented electric welding in 1855. With a battery of six Daniel cells he succeeded in fusing steel wires and uniting steel, brass, and platinum to iron. Again, his experiments proved that it takes $\frac{3}{4}$ lb. of zinc to fuse 1 lb. of iron. Some portion of Joule's library and apparatus is at the Manchester Technical School.

THE sixth annual Huxley lecture of the Anthropological Institute was delivered on Tuesday, October 31, by Dr. John Beddoe, F.R.S., ex-president of the institute; the chair was taken by Prof. Gowland. The lecturer chose as his subject "Colour and Race," and dealt mainly with the problems of Central Europe and the British Isles. After asserting the right of pigmentation to a high place among somatological data, Dr. Beddoe traced the history of the colour question, maintaining the correctness of his own methods as against those of Virchow and others; he showed, incidentally, that the latter gave incorrect results in certain areas. After adverting to the influence of heat, humidity, and various kinds of disease in causing selection of brunettes in certain localities, he passed on to explain in detail pigmentation maps of Central Europe which he had prepared; fairness was shown to increase from south to north, both in Europe and the British Isles, but it was open to question whether in the latter case historical rather than climatic grounds were not mainly operative. On the map of Ireland the traces of invading races were strongly marked; but in England the Saxons had not exterminated the preceding races, as was sometimes imagined. In conclusion, the lecturer asserted the probability of a change in the direction of dark pigmentation in this country, due to the predominant influence of the proletariat. The Huxley memorial medal was then presented to the lecturer by the president, and suitably acknowledged by the recipient.

IN an interesting article in the *Times* (October 28), some of the current theories on the ætiology of the disease known as "beri-beri" are reviewed. That of Dr. Hose, which ascribes the disease to the consumption of mouldy rice, is considered to accord with the facts better than any other. It must, however, be admitted that in the opinion of those best qualified to judge, this dietetic theory cannot be maintained. At the same time, it would be well, in the present state of our knowledge, to examine critically all theories, and it is stated that experiments are being made at Cambridge, under Prof. Sims Woodhead's direction, to test the truth or otherwise of Dr. Hose's theory.

AT a largely attended meeting of the Brighton and Sussex Medico-Chirurgical Society held at Brighton on October 27, Sir Frederick Treves gave an address on the Army Medical Service. He pointed out that in the South African campaign the admissions to hospital were 746 per 1000 on account of disease, and only 34 per 1000 for wounds. Our present medical department is totally inadequate, and a sufficient reserve must be created. Sir Frederick concluded by pointing out what appeared to him to be needed to make the Army Medical Service as perfect as possible. The points were:—(1) The Director-General should be the head of his department and be responsible for its efficiency and economical administration; (2) he should have direct access to the Army Council and Secretary of State; (3) he should have control of the money voted for the medical service; (4) the service remaining, as at present, "under the supervision of the Advisory Board"; (5) an efficient Army Medical Reserve should be formed; (6) the combatant officer should have some knowledge of hygiene as applied to campaigning and barrack life, and a like knowledge, of a still more elementary character, should be possessed by the private soldier; (7) the Army medical officer should be vested with such authority and provided with such *personnel* as would enable him to carry out those sanitary arrangements in the field which experience had proved to be absolutely essential to secure the *minimum* loss of life from disease.

DR. J. HUBER, of Pará, has sent us a separate copy of his paper on the formation of colonies in the ant *Atta sexdens*, from the *Biol. Centralblatt*, to which brief reference has already been made in these columns.

THE annual report of the Geological Survey of New Jersey for 1904 includes an illustrated account by Mr. C. R. Eastman of the Triassic fish-fauna of New Jersey, prefaced by a general popular dissertation on fossil fishes. This Triassic fish-fauna is singularly limited but remarkably constant throughout the eastern United States, from Virginia northwards, comprising only half a dozen generic types, of which four are severally represented only by a single species.

WE have received five numbers of the *Proceedings of the U.S. Nat. Museum*, the contents of four of which are devoted to the invertebrate faunas of America and the Philippines. New generic types of South American moths are discussed by Mr. H. G. Dyar in No. 1419, while other new forms of the same are described by Mr. W. Warren in No. 1421. A revision of North American fleas, by Mr. C. F. Baker, forms the subject of No. 1417, in which the author directs attention to the circumstance that fleas infesting rats in the tropics are more near akin to those which attack man than is the case with the rat-fleas of cooler climates, and to the bearing of this fact on the propagation of plague. Hymenoptera from the Philippines form the subject of No. 1424; while in No. 1425 Mr. W. H. Dall discusses the "Universal Conchologist" of Thomas Martyn, published in 1784, and the value of the technical names employed therein.

MUCH interesting information with regard to scientific progress in India will be found in the report of the Madras Government Museum and Connemara Public Library for 1904–5, drawn up by Mr. E. Thurston, who recently returned to his charge after a period of furlough in this country. The scheme for a systematic ethnographical survey of India, recently sanctioned by the Government, enters largely into this report, Mr. Thurston pointing out the difficulties connected with making such a survey in a country of the size of India, and referring to the somewhat unsatisfactory nature of the replies received from some of those who have undertaken to fill up papers connected with the subject. The museum is fortunate in having acquired the valuable series of prehistoric objects collected by Mr. R. B. Foote, late of the Indian Geological Survey, during his long residence in Madras. It may interest numismatists to learn that certain ancient lead coins kept in a wooden cabinet enclosed in an iron safe were found to be reduced to powder, the metal having been converted into carbonate.

WE have received separate copies of two papers by Francis Baron Nopcsa, the one from the *Geological Magazine* for July, and the other from the *Annals and Magazine of Natural History* of the same date. In the former the author describes, with a restored figure, a large portion of the skeleton of a large carnivorous dinosaur from the Oxford Clay of Oxford in the collection of Mr. J. Parker of that city. In place of referring this splendid specimen to the well known genus Megalosaurus, Baron Nopcsa considers that it indicates a genus apart, and he identifies it with Streptospondylus, typified by a few vertebræ and limb-bones in the Paris Museum from the Kimeridgian of Havre. Among other peculiarities, the Oxford dinosaur is stated to differ from Megalosaurus in possessing four (in place of three) hind-toes. It may be mentioned in this connection that Phillips, in his description of the typical species of the last named genus, expressly stated that he was uncertain whether there might not have been a fourth hind-toe. In the second paper the author gives a new interpretation of the problematical fossil Kerunia, from the Egyptian Eocene, which has been referred by one authority to a cephalopod and by a second to a hydractinian polyp. According to the author, both these authorities were to a certain degree right, for he regards Kerunia as a hydractinian in which a cephalopod took up its residence (symbiosis). The union of the two organisms was apparently so intimate that while the encrusting zoophyte undertook the construction of the shell of the mollusc, the latter controlled to a certain extent the growth of the zoophyte.

A RETURN has been published, we learn from the *Pioneer Mail*, regarding the measures adopted for the extermination of wild animals and venomous snakes during the year 1904. The total mortality among human beings reported to have been caused by wild animals was 2157, against 2749 in 1903. The most noticeable decrease occurred in Madras and the United Provinces, namely, from 438 and 404 in 1903 to 237 and 193 in 1904 respectively. In the Central Provinces (including Berar), also, there was an appreciable decrease—from 470 to 351. The destruction of human life by tigers in 1904 was smaller than in the previous year, the number being 786 against 866. As usual, the greatest mortality occurred in Bengal. The year's returns show a marked decline in the number of deaths caused by wolves—from 463 in 1903 to 244 in 1904, the decrease occurring principally in the United Provinces, where the mortality from this cause fell from 278 to 90. It is pointed out that the number of wolves destroyed in the United Provinces has fallen from more than 1200 in each of the years 1902 and 1903 to 650 in 1904; and the belief is expressed that this points to a genuine decrease in their numbers. The mortality from snake-bite rose from 21,827 to 21,880. It is reported that in the Seoul district of the Central Provinces anti-venin was used with success in two cases, and the question of introducing more generally the treatment of snake-bite by potassium permanganate is under the consideration of the local Government. The total number of snakes killed was 65,378.

DR. L. COCKAYNE contributes a short article on the far north of New Zealand to the *Young Man's Magazine* (August 1). The narrow strip of land lying north of the thirty-fifth parallel is for the most part a barren waste traversed by a few diggers of kauri gum. A belt of mangroves lines the estuary in Rangaumu Bay, and about North Cape are found the purple-flowered composite, *Cassinia amoena,* the crimson-flowered *Veronica speciosa,* and the curious leafless parasite *Cassythia paniculata.* Especially interesting is the Reinga, a rocky mass jutting out into the sea, whence, according to Maori lore, the Maori spirits took their final leap into the unseen world.

IT is interesting to find, as noted in the *Agricultural News* (September 9), that the new Barbados varieties of sugar-cane, known as B208 and B147, have yielded good results in Queensland; the latter seems to be especially hardy and proof against fungoid attacks. A remedy is suggested in connection with an unsatisfactory shipment of mangoes that the decay which is caused by fungi or bacteria acting on the bruised surface of the fruit may be in some measure prevented by immersion in a weak solution of formalin; it is said that with due precaution the formalin does not spoil even such delicate fruit as strawberries.

AT the beginning of this year an improvement was effected in the general style of the *Indian Forester,* and now, owing to the departure of two members of the controlling committee, a more permanent arrangement for a board of management, presided over by the Inspector-General of Forests, has been established. Mr. E. P. Stebbing, who continues to act as editor, discusses in the August number the *pros* and *cons* of fire protection in teak forests, and concludes with the recommendation to consider how fires can be controlled so as to yield the maximum benefit with a minimum of damage. He also furnishes the life-history of a cecidomyid fly which produces galls or pseudo-cones on *Pinus longifolia.* Mr. E. M. Hodgson presents an interesting account of the arrangements for fire protection in the Mandui range, Surat district.

IN Bulletin No. 26, Bureau of Government Laboratories, Manila, Dr. Richard Strong gives an admirable survey of the clinical and pathological significance of the *Balantidium coli,* a protozoon parasitic in man and swine, and causing diarrhœa and pseudo-dysentery.

THE contents of the *Bulletin of the Johns Hopkins Hospital* for October (xvi., No. 175) are chiefly devoted to medical subjects, but include an interesting summary of our present conceptions as to the cause of the heart beat by Mr. E. G. Martin.

THE *Journal of Anatomy and Physiology* with the October number commences its fortieth volume, and Sir William Turner, F.R.S., who has been an associate editor since its foundation, contributes a preface. The size of the page has been much enlarged, which, it is hoped, will be more advantageous for the reproduction of drawings. The number contains ten important articles and several excellent plates.

THE papers in the October number of the *Journal of Hygiene* (v., No. 4) maintain a high standard. Among others, Dr. H. S. Willson writes on a new process for the isolation of the typhoid bacillus from water by means of precipitation with alum, Mr. Crofton on anti-bacterial sera, Mr. de Korté on a sarcosporidium of a monkey, Dr. Graham-Smith on a piroplasma parasite of the mole, Dr. Nuttall on the prevalence of anopheles, Dr. Harden on the chemical action on glucose of the lactose-fermenting organisms of fæces, and Dr. Haldane on the influence of high air temperatures.

ATTENTION is directed in the *Engineering and Mining Journal,* of New York, to the remarkable developments at Mount Morgan, Queensland, whereby the mine of that name is being converted from a great gold mine into a copper mine. Diamond-drill borings have revealed large bodies of copper gold ore below the previous openings in the gold ore sufficient to warrant the erection of smelting works capable of treating 10,000 tons of ore monthly.

AT the first meeting of the autumn session of the Institution of Mechanical Engineers, an interesting paper on the manufacture of cartridge-cases for quick-firing guns, by Colonel L. Cubillo and the late Mr. A. P. Head, was submitted. The object of the paper was to describe the new plant recently completed at the Royal Spanish Arsenal at Trubia, Spain, for the manufacture of brass cartridge-cases from 3 inches to 6 inches in diameter.

A STRIKING photograph is reproduced in *Engineering* of October 27 showing the extraordinary erosive effect of the discharge from the Assouan dam. The whole of the water of the Nile passes through sluices in the face of the dam. These sluices are at different heights, so that water is never discharged under a head of more than 29·5 feet, which limits the velocity of discharge to less than 35 feet per second. Even at this velocity, however, the water has proved capable of lifting a boulder, weighing more than 60 tons, out of its natural bed in apparently solid rock, and hurling it back against the dam.

THE following method, requiring only a scale and a pair of dividers, for the measurement of angles is given in the *Engineer.* Suppose the length of an arc of 90° to be 90 mm., the length of the radius of the corresponding arch will be $180/\pi = 57{\cdot}3$ mm. Every millimetre, therefore, measured as an arc struck with this radius corresponds to an angle of 1°. For example, if an angle of 33° is required, describe an arc of 57·3 mm. radius and mark off upon it with a pair of dividers 10 mm. three times, and finally 3 mm. for the odd 3°. The method is equally applicable to British measures if the standard radius is taken at 5·73 inches, when the degree corresponds to one-tenth of an inch.

THE October issue of the *Journal of the Franklin Institute,* of Philadelphia, contains an account of the invention and development of the telautograph. Electric transmission of handwriting has received attention ever since telegraphic transmission of printed characters was effected. Prof. Elisha Gray exhibited a telautograph at Chicago in 1893, but cost and difficulty of manufacture led to its abandonment. The instrument has been brought to its present state chiefly through the experimental work of Mr. G. S. Tiffany. It is a variable current instrument with several interesting features, including what may be termed a straight line D'Arsonval movement, which is used to work the receiver. A large number of private line telautographs are now in actual use in the United States.

IN a series of papers in the *Proceedings of the Royal Society of Victoria* (n.s., vol. xviii., part i., August) Messrs. Thiele, Chapman and Hall add to the knowledge of the Palæozoic rocks and fossils of Gippsland. A series of graptolites, including both some new forms and several

well known British species, mark the Ordovician age of certain black slates; a new species of Receptaculites comes from Silurian rocks, while some Devonian fossils are re-described.

THE frequent association of the acid igneous rock granophyre with the basic gabbro has attracted the attention of many geologists, and two explanations have been offered—(1) that the two rocks have been differentiated, during slow consolidation, out of a uniform magma of intermediate composition; and (2) that one of them represents the unaltered original magma, while the other has been formed by part of it absorbing and assimilating foreign material. Mr. R. A. Daly, of the International Boundary Commission, describes (*Amer. Journ. Sci.*, 4th ser., vol. xx., No. 117, September) cases he has observed in British Columbia and elsewhere which appear to him to prove conclusively the second theory to be correct. Gabbro-sills, intrusive in a quartzite, have been converted into an acid rock along the upper contact by absorption of silica from the quartzite, the other rock constituents retaining very nearly their original proportions.

WE have received the report on rainfall registration in Mysore for 1904 prepared by Mr. J. Cook, director of meteorology in that province; it contains valuable statistics relating to the seasonal and geographical distribution over that extensive area. The number of Government stations is now 201; but with regard to a few of the stations the director has to lament culpable inattention on the part of the officials concerned, who have allowed the gauges to lie for months without being suitably fixed. Among the heavy falls in twenty-four hours may be specially mentioned 20·67 inches in June, in the Shimoga district, and 13·70 inches in July, in the Kadur district. The geographical distribution is plainly exhibited by two maps, one for the year 1904, and another showing the average for thirty-five years, 1870–1904; the abnormality of the distribution owing to the failure of the north-east monsoon rains is strikingly represented. The thirty-five years' average for the whole province is 37·12 inches; the average for the Kadur district is 74·26 inches, and for the Chitaldrug district 21·46 inches.

PROF. STOUT's paper on "Things and Sensations," read to the British Academy in May, has been published by Mr. Henry Frowde. Prof. Stout maintains that the problem for philosophy is not, Is there an external world? but *What* is the external world, and how do we know it? He points out that in one aspect the thing and its sensible appearance are regarded as entirely one, and in another aspect as separate and independent. He rejects the solution that the sensible appearance is merely the thing itself appearing, examines hastily but suggestively the views of Locke and Kant, and comes to the conclusion that there is an actual existence other than sensation. This he calls the independent not-self, and he describes it as not unknowable and as not matter, but only one constituent of the complex unity which we call matter. In the concluding section of his admirable essay he argues that we must apprehend this independent not-self as another self, or as a partial aspect of another self more or less like our own.

THE fifth volume of the new series of the *Proceedings of the Aristotelian Society* has been published by Messrs. Williams and Norgate at 10*s.* 6*d.* net. The volume includes the papers read before the society during the session 1904–5, an abstract of minutes of the proceedings, and the report of the executive committee.

THE first two parts of a "Three Years' Course of Practical Chemistry," by Messrs. George H. Martin and Ellis Jones, science masters of the Bradford Grammar School, have been published by Messrs. Rivingtons at 1*s.* 6*d.* each. The second part, dealing with the work of the second year of the course, was originally published privately, and was reviewed in our issue for December 1, 1904 (vol. lxxi. p. 100). An introduction to each volume has been provided by Prof. J. B. Cohen.

AMONG the articles in the current number of the *Quarterly Review* is one dealing with the aborigines of Australia, written by Mr. Andrew Lang. This article reviews the work of the chief observers of the primitive peoples of Australia, examining exhaustively the researches of Mr. A. W. Howitt, Mr. F. J. Gillen, and Prof. Baldwin Spencer. Mr. Lang differs from all these on some points of theory, though he is profuse in his admiration of the matter and manner of their work, except as regards linguistic and philological research. The hypothesis put forward by Mr. Lang is the converse of that apparently entertained by Messrs. Spencer and Gillen. To quote the concluding paragraph of the article:—"they probably regard the Arunta lack of religion as primitive, just as they think the totemism of the Arunta most archaic. They do not indulge in the comparative method in either case; and it is the comparative method that leads us to our conclusions." The same number of the review contains an article on food supply in time of war.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER:—

Nov. 3. 13h. 35m. to 14h. 56m. Transit of Jupiter's Sat. III. (Ganymede).
,, 5. 10h. 59m. to 12h. 4m. Moon occults σ Aquarii (mag. 4·8).
,, 9. 15h. 52m. to 16h. 51m. Moon occults ν Piscium (mag. 4·7).
,, 13. 6h. 35m to 7h. 16m. Moon occults α Tauri (mag. 1·1).
,, 13. 9h. 7m. Minimum of Algol (β Persei).
,, 14–16. Epoch of Leonid shooting stars (Radiant $151° + 23°$).
,, 15. Venus. Illuminated portion of disc $= 0·930$. Of Mars $= 0·879$
,, 16. 5h. 56m. Minimum of Algol (β Persei).
,, 17–21. Epoch of Andromedid shooting stars, with probable maximum November 18 (Radiant $25° + 43°$)
,, 20. Saturn. Major axis of ring $= 39''·62$, Minor axis $= 7''·88$.
,, 23. 21h. Jupiter in opposition to the Sun.
,, 24. 18h. Venus in conjunction with the Moon. Venus 3° 42′ S.
,, 26. 17h. Mercury at greatest elongation, 21° 41′ E.
,, 27. 18h. Mercury in conjunction with the Moon. Mercury 6° 33′ S.

WAVE-LENGTHS OF SILICIUM LINES.—Because of their especial utility in radial-velocity determinations, Prof. Frost and Mr. J. A. Brown have re-measured the wave-lengths of the silicium lines at $\lambda\lambda$ 4553, 4568, and 4575, which were simultaneously identified by Sir Norman Lockyer and Mr. Lunt, and designated "group iii." by the former observer.

The three spectra measured in this new determination were obtained by passing a strong spark between poles containing metallic silicium and titanium, the sharp titanium lines providing useful standards of wave-length in the subsequent calculation. As a titanium line occurs near enough to the silicium line at λ 4553 to interfere with the measures of the latter, only those photographs were used on which the faintness of the other titanium lines showed that this possible source of error might be neglected.

As a result of this research the following values were obtained for the wave-lengths sought:—λ 4552·64,

λ 4567·90, and λ 4574·70. The values obtained by previous observers are given below for comparison:—

	λ	λ	λ
Gill (from stars)	4552·79	4567·90	4574·68
McClean (from stars)	4552·6	4567·5	4574·5
Lockyer (spark)	4552·8	4568·0	4574·9
Exner and Haschek (spark)..	4552·75	4567·95	4574·9

The importance of having the exact wave-lengths of these lines in stellar radial-velocity determinations is shown by the differences which would be introduced into Prof. Frost's recent work on the *Orion* stars by the change from Exner and Haschek's values, as given above and previously used by Prof. Frost, to the new wave-length values. They are as follow:—

λ	Correction (Frost and Brown—Exner and Haschek) In λ	In kilometres
4553	−0·114 tenth-metres	= −7·51
4568	−0·053 ,,	= −3·48
4575	−0·109 ,,	= −7·14

REPORT OF THE YERKES OBSERVATORY.—Prof. Hale's report of the work performed at the Yerkes Observatory during the year ended June 30, 1904, has just been received, and shows that, during that period, neither the results obtained nor the private pecuniary support accorded to the institution fell below the average of previous years.

The Carnegie Institution of Washington has renewed the grant of 4000 dollars made to the observatory for the previous year, and the money is to be employed in furthering the investigations of stellar parallaxes, the observations of variable stars, and the reduction of the solar photographs obtained with the spectroheliograph of the Kenwood Observatory during the years 1892–5.

The Snow telescope, which was destroyed by fire in December, 1902, has been rebuilt from a gift of 10,000 dollars made by Miss Snow, and has since been erected at the Mount Wilson Solar Observatory.

A gift of a further 10,000 dollars from the Carnegie Institution provided for an expedition, for solar research, to Mount Wilson, where an independent observatory has since been erected under the direction of Prof. Hale, who thus severs his more immediate connection with the Yerkes Observatory.

The Bruce telescope having an aperture of 10 inches and a focal length of 50 inches has now been completed, and, under the direction of Prof. Barnard, is yielding splendid results. This telescope gives sharp definition over a field about 9° in diameter.

The 40-inch refractor is used for the Rumford spectroheliograph, the Bruce spectrograph, and several other attached instruments, and continues to give increased satisfaction.

After describing the above, Prof. Hale gives a somewhat detailed account of the excellent work performed in each department, and thereby shows what an important place in the astronomical world is filled by the Williams Bay observers and observatory.

OBSERVATIONS OF JUPITER'S SIXTH SATELLITE.—The results of a series of photographic observations of Jupiter's sixth satellite, made at Greenwich with the 30-inch reflector of the Thompson equatorial during August, September, and October, are published in No. 4051 of the *Astronomische Nachrichten*. Thirteen photographs were obtained on eight nights, and the time and length of each exposure, and the position angle and distance determined therefrom, are given in the table published. So far as possible, the two latter quantities have been compared with those given by Dr. Ross's ephemeris which appeared in No. 4042 of the *Astronomische Nachrichten*, and the differences are appended.

In order to facilitate the measuring process, the over-exposed image of Jupiter, on each plate, was reduced with ferricyanide of potassium, leaving an easily measurable reversed image, but the present results are to be considered as only provisional.

THE SPECTRUM OF NOVA PERSEI NO. 2.—No. 3, vol. lvi., of the Harvard College Observatory Annals contains a detailed *résumé* of the spectroscopic results obtained at the observatory in connection with Nova Persei No. 2.

Particulars of the photographs obtained are first given, and then each plate is discussed in order, and a description of the spectral changes and of the principal lines in the spectrum given. Special remarks are made in reference to any peculiar appearance or changes in the spectrum, such as took place when the star was rising to its maximum brightness and subsequently when its magnitude was oscillating. In this connection an interesting comparison is drawn between the changes which take place in the spectrum of Mira Ceti during the light-variations of that star and those which were observed in the Nova spectrum. From this comparison it is deduced that both in the case of Novæ and variable stars of long period the hydrogen lines do not become bright until the star has attained a large portion of its light.

REDUCTION TABLES FOR EQUATORIAL OBSERVATIONS.—Appendix No. 3 to vol. iv. of the Publications of the U.S. Naval Observatory contains a series of tables for the reduction of equatorial observations.

These tables have been compiled by Mr. C. W. Frederick, who, in the introduction to them, develops the formulæ for the construction of the tables of differential refraction for micrometer observations made with an equatorial, describes a method of determining the instrumental constants, and explains the use of the six tables included in the work.

The first three tables show the corrections for differential refraction, for the latitude of the Washington Observatory, to be applied separately according to the method of observation pursued.

Tables iv., v., and vi. give the instrumental constants of the 26-inch equatorial, of the Naval Observatory, for use under analogous conditions.

PHOTOGRAPHIC STAR CATALOGUE.—From a communication made by M. Lœwy to the Paris Academy of Sciences, we learn that the first volume of the "Catalogue photographique du Ciel" has been published by the Bordeaux Observatory, relating to the region dec. +16° to +18°, which they undertook to observe. This volume contains the rectilinear coordinates of 49,772 stars, and completes the set of four similar publications undertaken by the French observatories (Algiers, Paris, Toulouse, and Bordeaux) as part of the international cooperative scheme (*Comptes rendus*, October 9).

GEOGRAPHY AT THE BRITISH ASSOCIATION.

IN arranging the programme of work for the South African meeting, the organising committee of Section E tried to secure papers summarising the geographical conditions of the "subcontinent," as it is locally called, or those dealing with general geographical problems. The number of papers by South Africans was smaller than might have been expected, the local committee discovering that geography was the subject for which it was most difficult to secure papers. South Africa is in the position of having many specialists interested in geographical aspects of their specialisms, but has as yet no geographers giving all their time and energy to the subject.

In spite of this, the programme of the section was a full one, and it would have been difficult to dispose of more business than was accomplished.

It will be most convenient to consider first those papers which deal with Africa.

Mr. H. C. Schunke Hollway, vice-president of the section, communicated a paper on the outlines of the physical geography of the Cape Colony. This was illustrated by a new orographical map specially prepared by the Surveyor-general, Mr. Cornish-Bowden, showing contour lines at 1500, 3000, 4000, 6000, and 8000 feet. Unfortunately, sufficient data for plotting the 500-feet contour line—one of the most interesting of all—do not exist; and even the lines shown on this map are only approximations. Here, at the outset, the lack of a good topographical map was bewailed, and throughout the wanderings of the members in South Africa this deficiency was felt at every

turn. Mr. Schunke Hollway traced the first efforts to obtain levels, and showed how the railway surveys had been the chief means of securing the knowledge we possess of relief. He then discussed the natural divisions of the Cape Colony, distinguishing (1) the coast, and (2) the Orange River basin. The coast, varying from 80 miles to 170 miles wide, he divided into (*a*) the eastern region, a narrow tract of land which rose in terraces from the sea, east of the south-east sweep of the Sneeuwbergen, Tandjesbergen, and Bankberg ranges, to where it dipped into the Fish River, and along that river to the sea; (*b*) the south-western region, which nearly coincided with the folded mountain belt, and stretched as a narrow zone of mountains not more than 85 miles wide from the Olifants River in the west to the Fish River in the east; (*c*) the lower Karroo region, a comparatively narrow strip of land between the southern mountain belt and the watershed, which extended from Uitenhage and Somerset East to the north end of the Bokkeveld Karroo, south of Calvinia; (*d*) the north-west coast region, which lay between the Olifants and the Orange rivers. The Orange River region consisted broadly of a hollow plain which sloped gently from east to west, with but few isolated ridges and hills scattered over its surface. It was 1000 miles long, rose to more than 3000 feet within 80 miles of the coast, and remained above this height for 250 miles in width. Seen from the tableland, the Roggeveld and other bordering mountains seemed insignificant, but seen from the Karroo the escarpment presented the appearance of a magnificent mountain range. This rose to the Drakensbergen or Kahlamba mountains in the east, 180 miles of which lay within the colony, with an average ridge level of 8000 feet. In the west, valleys containing settlements at more than 6000 feet were to be found. After a detailed examination of each region, its economic conditions were briefly discussed, and their relationship to rainfall pointed out.

The physical geography of the region further north was discussed in Mr. Tudor Trevor's paper on the physical features of the Transvaal. He divided the country into:—(1) the plateau country or High Veld; (2) the slopes of the plateau locally called Banken; and (3) the basement country locally called Low or Bush Veld. These were subdivided as follows:—

		Square miles	Per cent
High Veld	True High Veld	14,900	12·7
	Middle Veld	18,800	16·0
	Outliers (Zoutpansberg and Waterberg)	4,400	3·7
	Total	38,100	32·4
Slope Country	Main Slope	19,700	16·7
	Outliers (Zoutpansberg and Waterberg)	7,400	6·3
	Total	27,100	23·0
Low Veld		52,000	44·6
	Total	117,200	

He described the water systems and pointed out the absence of alluvial deposits, and directed attention to the steady diminution of the water in springs in recent historic times.

Mr. F. S. Watermeyer dealt with a wider area in his geographical notes on Africa south of the Limpopo. He gave a brief historical sketch of the cartography of South Africa, a summary of the history of its population, and an account of the physical features and climatic conditions, especially with regard to the influences on the development of pastoral and agricultural pursuits.

Mr. C. Stewart, Government meteorologist, communicated at Cape Town a paper on the climate of South Africa. The uniformity of mean annual temperature was pointed out—the Royal Observatory, Cradock, Bloemfontein, and Johannesburg being all about 62° F.—the higher altitude neutralising the lower latitude. The mean temperature curve was at a maximum in February; it fell rapidly until June, slightly to July, and rose with a peculiar flattening in September to the maximum. The minimum of the year occurred in a cold spell in July. The flattening in September was associated with an increase in the cloud curve coincident with the change in the prevailing winds from north-west in August to south in September. As to rainfall, there were three regions:—(1) the south-west winter rain region; (2) the small area in the south of constant rains; and (3) the east, with summer rains. Rain came with north-westerly winds in the west, with south-westerly winds in the south and east, and sometimes with north-easterly winds in the east.

Remarkable winds, locally called "Berg winds," blew from the plateau at right angles to the coast and raised the temperature. At Port Nolloth they blew when depressions were commonest in South Africa—from autumn through winter to spring—and made it warmer in winter. The storms of South Africa were associated with Λ depressions, and so were similar to those of southern Australia.

Mr. Hutchings read a paper on the indigenous forests of South Africa. He divided them into:—(1) the dense evergreen indigenous forests of which yellow-wood was the chief species, commonly called the yellow-wood forest; (2) the open timber forest, which generally occupied drier country than the yellow-wood forest, and was of inferior type, though it might contain trees of first importance, such as the cedar forest of Clanwilliam and the Rhodesian teak (*Afzelia cunanzensis*) forest of Wankie; (3) the scrub forests of the dry, hot coastlands and portions of the interior, where the rainfall was scanty and uncertain. There was no timber of large size in the scrub forests, and not much in the open timber forests. The yellow-wood forests were found in the rainy regions of the south coast, where they appeared as dense evergreen woods disposed in two storeys. The lower storey was formed by stinkwood, assegai, hard pear, ironwood, &c., and the upper storey by the large yellow-wood trees, which attained the stature and dimensions of the largest oak trees in Europe. For 1200 miles from Cape Town to the north-east Transvaal the species remained much the same, but in the Rhodesian forests most of the trees were deciduous and of different species to those of the yellow-wood forest.

Major Stevenson Hamilton, warden of the game preserves, gave an interesting account of the past and present distribution of game in the Transvaal, and of the attempts which were being made, with gratifying success, to prevent its extermination.

Two papers dealt with Africa as a whole. Mr. J. Bolton discussed the boundaries and areas more particularly of British colonies and protectorates. The boundary treaties and agreements which have resulted in boundary surveys were specially treated, as these surveys are almost the only pieces of scientific map-making in the continent.

Messrs. Herbertson and Waite showed a new map of the annual rainfall of Africa, based on all available data.

Two papers were communicated on surveying and mapping. The triangulation of the gold fields was described by Mr. van der Steer, who had helped Mr. Melville, vice-president of the section, to carry out the triangulation of the central and most important section. This paper will be published in full in the *Journal of the Institute of Land Surveyors of the Transvaal*.

Colonel Johnston, late director-general of the Ordnance Survey, gave a very clear account of the history and work of the survey, and described the various maps which it issues, illustrating his remarks by specimens and by lantern slides. He pointed out the various advantages to be derived from a topographical survey of South Africa, and showed that it need not be so expensive an operation as was commonly supposed.

There were very few papers dealing with geographical exploration. At Cape Town Mr. L. Bernacchi lectured on the results of the National Antarctic Expedition with the *Discovery*, in which he paid special attention to the magnetic and meteorological results. Mr. Ferrar, another member of the expedition, gave an evening lecture at Pietermaritzburg on the same subject. A paper on the volcanic Gough Island, by Mr. Rudmose Brown, of the

Scottish Antarctic Expedition, was read at Cape Town. Two new buntings, a rich marine fauna, and three new species of plants were obtained. The desirability of further exploration from South Africa was pointed out. In the course of the discussion it was suggested that a meteorological station on Gough Island might be of use to South African weather services. Mr. Yule Oldham gave a summary of the history of the discovery of the coasts of Africa, illustrated by an admirable selection of lantern slides of contemporary maps, showing the various stages in the progress of discovery. The proceedings at Johannesburg were opened by Mr. Douglas W. Freshfield, who described the Sikhim Himalayas, and the route followed by our troops towards Lhasa; this was the only other record of travel. Mr. Freshfield delivered one of the evening lectures at Durban, choosing for his subject "Mountains."

Some interesting discussions took place on questions of physical geography at a joint meeting with the geological section, an account of which will shortly be published. At Johannesburg, Prof. Davis, of Harvard, communicated a paper on the geographical cycle in arid areas—a deductive essay based on observed facts. Starting from suggestions in Prof. Passarge's great work on the Kalahari Desert, he traced the probable sequence of land forms in an elevated and arid region rarely subjected to water erosion, illustrating his remarks by admirable blackboard sketches. He pointed out that, starting with a rough, uneven land, the occasional water erosion would not be related to sea-level, and at an early stage the depressed areas would be slowly filled up, forming lakes of rock waste. In course of time, the slopes would be so worn down and adjacent basins so filled that one communicated with its neighbour. Ultimately a large "integrated" basin would be formed; wind action would increase with smoothness, and might even transport waste outside arid area. This would waste the whole surface and reduce it to a common level, and wearing away by wind might even lower the surface below sea-level. It was suggested that wind erosion might explain the pans of the Transvaal, the origin of which had occasioned considerable speculation.

Two papers were of special interest to teachers of geography. Captain Ettrick W. Creak, F.R.S., vice-president of the section, maintained that the use of globes was essential in teaching geography, and that systematic lessons should be given with globes.

Mr. J. Lomas showed how excursions could be used in teaching geography, and illustrated his points by views taken on some excursions which he had conducted.

The committee of the section asked for the re-appointment of the committees on researches in the Indian Ocean, and on the local names given to geological and topographical features in different parts of the British Isles. They, along with sections B, C, and E, asked for the appointment of a committee to report on the quantity and composition of rainfall and the discharge of lakes and rivers in different parts of the globe.

The whole journey from England to the Victoria Falls and back may be regarded as the longest, most interesting, and most profitable geographical excursion ever made by the section. This has been described in NATURE by another pen, and so need not be recapitulated here. In South Africa the most elaborate special excursions were those arranged by the geologists, and the long trek from Pretoria to Mafeking. These permitted members to see the country more intimately than was possible from the train. The thanks of those geographers who were allowed to take part in these must be recorded.

Since the above was written, the sad news has come that the president of the section, Admiral Sir William Wharton, died at Cape Town on Thursday, September 28, after a short illness. The value of the proceedings in this section was greatly increased by his intimate knowledge of many parts of the world, by his keen interest in all geographical problems, and by the genial way in which he induced those present to take part in the discussions. An account of his career was given in NATURE of October 12 (p. 586), but the writer may be permitted to say how very much the success of the meetings of the geographical section was due to the president, whose loss will be deeply deplored by all who were privileged to come in contact with him.

THE CHELSEA POWER STATION.[1]

THE development of electric traction as applied to railways in Great Britain is about to make one more step forward with the electrification of the underground railways in London, and as this scheme is almost complete, a short description of the power scheme may be of interest.

In most large power schemes that have been completed during the last few years, it has not always been convenient to place the main power station near the centre of the system of power distribution, owing to cost of ground, &c., but this difficulty is got over by employing a number of small distributing stations which are conveniently situated in the area of supply, and are supplied with power from a large main generating station.

The main generating station of the underground electric railway will supply the entire power necessary for the working of the Inner Circle, which it is working in conjunction with the Metropolitan Railway Company's station at Neasden, and for the whole of the District Railway. It will also furnish power to the Baker Street and Waterloo, and the Great Northern, Piccadilly, and Brompton tube railways on their completion.

Coal for the boilers' furnaces is lifted out of barges by two large cranes, each working a 27-cwt. grab bucket, which deposits it in a holder where it is automatically weighed. From the holders the coal is carried by means of automatic conveyors to the coal bunkers, which are situated in the top of the boiler house immediately over the boilers. The coal falls from these through chutes to automatic stokers as required, and as the ash accumulates beneath the boiler furnaces it is removed by means of an ash railway. Thus the handling of the coal is almost wholly automatic from the moment the coal leaves the barges until it is returned to the barges as ash.

The boiler house consists of a basement and two floors, and is 450 feet long by 100 feet wide. In the basement there are eight pumps for pumping the water into the boilers. The boilers are on two floors, each containing thirty-two boilers, with floor space available for eight more boilers on each floor should they be required. They are divided into groups of eight, and each group supplies steam direct to the steam turbine engine to which it is permanently connected. Each group is fitted with economisers for heating the water before it is pumped into the boilers.

The main engine-room is 75 feet wide by 450 feet long, and consists of a basement and one floor.

The eight horizontal steam turbine engines are each coupled direct to a three-phase alternating current generator, and it seems hardly conceivable that each one of these sets is capable of transforming the heat energy of the coal into electrical energy equivalent to 7500 horse-power, while the total output of the station is 76,000 horse-power. The electrical generators are of the fixed armature type, having a four-pole revolving field, and generate at a pressure of 11,000 volts. A system of forced lubrication is employed on the turbines, thus ensuring efficient lubrication.

In addition to the above, there are four high-speed engines of 175 horse-power connected to generators which supply the magnetising current for the revolving fields. The condensing system for condensing the steam after it has performed its useful functions in the engines is very ingenious, and is so arranged that the pumps for pumping the cooling water through the condensers have merely to overcome the friction of the pipes.

One of the most interesting features of the whole system is the switch-board and control system. The system employed aims at having the entire control of the generating in a small space, and at the same time having no dangerous voltages on any part of the control board.

The system is almost analogous to the nervous system of the human body, having the control board as the brain, which it virtually is. All the big high-voltage switches are operated by small electric motors, and it is these motors which are operated from the control board, and as a low-voltage current is used for this purpose

[1] Abstract of a paper read before the students' section of the Institutio of Electrical Engineers by Richard F. Chaffer.

there is little or no danger to the operator through faulty switch-gear.

The switch-board proper is carried by three galleries extending the whole length of the north side of the engine-room and continued along the east end. The control board is on the middle gallery and projects slightly, so that the operator has a clear view up and down the engine-room. From the switch-board the energy is distributed to the various substations situated at various points along the system, and it is there converted to low-voltage direct current at 550 volts, and thence distributed to the live rail. Throughout the whole station it is remarkable to find the extent to which labour-saving devices are employed.

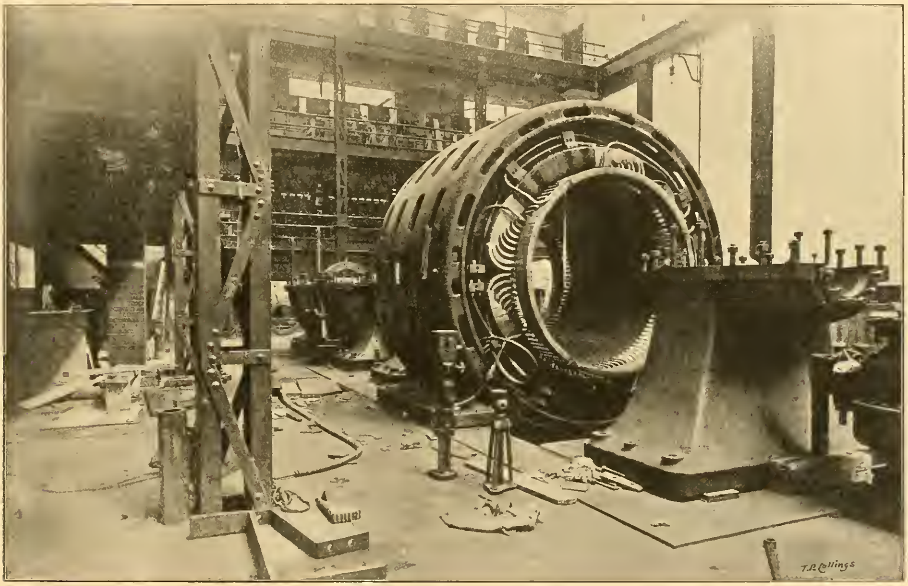

FIG. 1.—Armature of 5500 K.W. Generator.

Thanks are due to Mr. Chapman, general manager and chief engineer, for permission to view the station, and to the Institution of Electrical Engineers for the accompanying illustration of the armature of one of the generators.

REPLICAS OF DIFFRACTION GRATINGS.

FROM an article in No. 2, vol. xxii., of the *Astrophysical Journal*, we learn that Mr. R. J. Wallace, of the Yerkes Observatory, has attained great perfection in the production of replicas from plane diffraction gratings. After some amount of previous research, he decided on following Thorp's method in its essentials with several modifications which his experience suggested. Mr. Thorp first flooded his original grating with high-grade oil before pouring on the celluloid solution on which the replica was made. Mr. Wallace found it better to omit the oil. In the original method a solution of gun-cotton in amyl acetate with camphor added was employed as the material for the replica, but Mr. Wallace found that he could obtain much clearer and brighter copies by not adding the camphor. His successful solution is made by dissolving 38 grains of Anthony's pure snowy cotton in $2\frac{1}{4}$ ounces of pure amyl acetate, precipitating the resultant collodion in a large tray of pure water—constantly agitating the mixture—thoroughly drying the precipitate, and then re-dissolving it in the same quantity of pure amyl acetate. The collodion thus obtained is carefully filtered, and is then ready for use.

The grating to be copied is levelled in a roomy drying cabinet, which, in order to preclude dust particles, should be as free from draughts as possible, the surface dusted with a soft camel-hair brush, and the collodion flowed over it evenly. The author uses about twenty-five drops of the solution in copying a 2-inch grating. The grating is then replaced on the levelled support and left to dry for about eight to twelve hours; the longer the drying period the better is the resulting copy. After being thoroughly dried the grating is placed in pure distilled water at normal temperature together with the glass ("white optical crown") support, which has previously been evenly coated with the adhesive medium, plain hard gelatin. After a few minutes' soaking the edge of the film may be sprung from the grating, and the whole of it is then detached and *immediately* placed on the previously prepared gelatin surface and clamped there. Perfect contact is obtained by drawing a piece of the softest velvet rubber *very lightly* over the surface in the direction of the length of the lines.

The contraction suffered by the replica during the twenty-four hours' drying period slightly alters the number of lines per inch, but the effect is very small. In some of Mr. Wallace's copies this alteration produced 572 lines per mm. instead of the 568 lines that occupied the same space on the original. Two reproductions of the solar spectrum, one taken with the original grating, the other with the copy, show the resulting increase of dispersion caused by the contraction, and also show that everything which is resolved by the original grating is also resolved equally well under the same conditions by the copy.

The grating replicas, unmounted, transmit the more refrangible radiations up to λ 2013, practically without absorption, but the glass used as supports for the copies is opaque beyond λ 3400, therefore Prof. Wood has proposed that mica should be employed for the supports where "ultra-violet" work is to be prosecuted. Reproductions of some spectrograms obtained with and without the mica screens show the value of Prof. Wood's suggestion.

Mr. Wallace recommends the "copying" process as the most efficient method of cleaning a dirty grating, and he has also tried it for the production of replicas of concave gratings, but as yet without any notable success.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Mr. T. S. Moore has been elected to a fellowship at Magdalen College after an examination in chemistry. Mr. Moore was educated at the East London Technical College; he gained a postmastership in natural science at Merton in 1898, was placed in the first class in mathematical moderations in 1900, and in the natural science school in 1902. He was lately appointed lecturer in chemistry in the University of Birmingham.

St. John's College recently procured an important change in its statutes which will be of great assistance in the new forestry scheme. The college was bound by the statutes of 1877 to endow a chair of mechanics and civil engineering so soon as its revenue permitted; by the new statute this obligation is removed, and instead St. John's is to contribute in and after 1908 600*l.* a year to the Sibthorpian professorship of rural economy. It is understood that the main subject to be entrusted to the future professor is pathological botany, so that he will have an important share in the instruction of the forestry students. St. John's has also placed a considerable plot of land near Bagley Wood at the disposal of Prof. Schlich for the purpose of starting a "forest garden."

At the first meeting of the delegacy which is to superintend the instruction of the Indian forestry students Prof. Schlich was appointed secretary, and Mr. D. H. Nagel (Trinity College) assistant secretary.

Prof. Osler and Prof. Miers were among the new members of the hebdomadal council who were elected on October 26.

The examinations for natural science scholarships this term will take place at the following dates: December 5, Balliol, Christ Church, and Trinity; December 12, University, Lincoln, and Magdalen; December 19, Jesus College.

CAMBRIDGE.—A memorial has been presented to the council of the senate requesting the council to take steps by the nomination of a special syndicate or otherwise to ensure the consideration of the following questions:—(1) the advisability of imposing on all such candidates, as may not otherwise be qualified for exemption, the passing of the previous examination or of another examination, in lieu of the previous examination, as a condition precedent to matriculation in the university; (2) the possibility of obtaining the cooperation of the University of Oxford with the University of Cambridge in establishing a joint examination which should qualify for matriculation in either university. This memorial has been signed by some seventy influential members of the university. It has been referred by the council of the senate to the studies and examinations syndicate.

The electors to the Allen scholarship give notice that they are prepared to receive applications from candidates. Any graduate of the university is eligible for the scholarship provided that his age on the first day of the Lent Term 1906 does not exceed twenty-eight years. Next year the scholarship is open to candidates who propose to undertake research in medicine, mathematics, physics and chemistry, biology and geology, moral science. The scholarship is tenable for one year, during which period it will be the duty of the student to devote himself to research in Cambridge or elsewhere. The emolument of the student is 250*l.*, or such smaller sum as the fund, after payment of all expenses, shall be capable of providing. Every candidate must send to the Vice-Chancellor, Trinity Hall Lodge, on or before February 1, 1906, his name and a definite statement of the course of research which he proposes to undertake, together with such evidence of his qualifications as he thinks proper, and with the names of not more than three referees to whom the electors may apply for information. The election will be made towards the end of the Lent term, 1906.

In its report upon its reserve fund, the museums and lecture rooms syndicate enumerate a number of varying sums spent upon the museums. It has granted 100*l.* toward the expenses of housing Prof. Bonney's collections in the Sedgwick Museum, and has also allotted some smaller sums to the furnishing of the rooms in the new medical schools. It is a pity there are not sufficient funds at the disposal of the syndicate to fit up the Humphry Memorial Museum, the bare walls of which cry for shelves and showcases.

THE annual general meeting of the Association of Teachers in Technical Institutes will be held at the Birkbeck College on Saturday, November 4, at 3 p.m., with Mr. W. J. Lineham, chairman of the association, in the chair.

A COURSE of eight lectures on fields of force will be given in Columbia University, New York City, by Prof. V. F. K. Bjerknes, professor of mechanics and mathematical physics in the University of Stockholm, on Fridays and Saturdays in December. The lectures will be open, without charge, to teachers and advanced students in physics. During March and April, 1906, a course of lectures will be given by Prof. H. A. Lorentz, professor of physics in the University of Leyden.

THE Berlin correspondent of the *Times* states that in the presence of the German Emperor, the American Ambassador, the German Foreign Secretary, the Prussian Minister of Education, and other men of distinguished eminence, an inaugural lecture was delivered in English by Prof. Peabody, of Harvard University, in the central hall of Berlin University on Monday, October 30. Prof. Peabody discussed the advantages of the scheme put forward by the German Emperor for the exchange of lecturers between German and American universities, and read a letter which he had received from President Roosevelt approving of the scheme.

WE have received an advance copy of the report of the work of the department of technology of the City and Guilds of London Institute for the session 1904–5. The report refers to some of the ways by which the institute is able to cooperate with the central educational authorities for Great Britain and Ireland, in assisting and guiding schools in their arrangements for the provision of technological instruction, and in effecting a proper coordination between workshop and class teaching. The department of technology suggests schemes for complete courses of evening instruction for artisans and others engaged in different industries, and prepares detailed syllabuses in the technology of each trade subject. The institute registers classes in any of the subjects contained in its programme, provided the conditions preliminary to registration are fulfilled. During the past session 2601 classes were registered in 364 towns. These were attended by 41,618 students, being 671 more than in the previous session. Before registering a class, the institute requires that the qualifications of the teacher shall be submitted to, and approved by, the department of technology. During the session under review, 195 new names have been added to the institute's register of teachers in technology, and 149 have been provisionally approved. The institute has inaugurated a system of inspection of trade classes by professional experts. During the past session 149 classes were inspected by members of the institute's staff. The report also contains full statistics relating to affiliated technological classes, and instructive extracts from some of the examiners' reports on the results of the examinations, 1905.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, October 18.—Dr. T. A. Chapman, vice-president, in the chair.—Mr. H. **Rowland-Brown** exhibited series of Erebias taken this year in the Pyrenees, including *Erebia lefebvrei*, with the varieties *pyrenaea*, Obth., from Mt. Canigou, E. Pyrenees, and var. *intermedia*, Obth., from Gavarnie. He also showed for comparison *E. glacialis* var. *nicholli*, from Campiglio, which at one time was supposed to be identical with *lefebvrei*, then considered to be the Pyrenean form of *E. melas*; specimens of *E. gorgone* and *E. gorge* from the Lac de Gaube, Cauterets, and from Gavarnie; and a short series of *Lycaena orbitulus* from the Central Alps, *L. orbitulus* var. *oberthuri*, Stgr., *L. pyrenaica*, and *L. pheretes* from the Brenner and Cortina districts. It was remarked that there seemed to be a greater superficial affinity between *pyrenaica* and *pheretes* (not reported from the Pyrenees) than between *pyrenaica* and *orbitulus*.—Mr. E. C. **Bedwell** exhibited eight specimens of *Apion laevigatum*, Kirby, one of the rarest indigenous Apions, found on August 31, sheltering under plants of *Echium vulgare* in the Lowestoft district.—Mr. R. **Shelford** showed a Ligæid bug, the fore-limbs of which were remarkably well adapted to fossorial habits and comparable with those of the mole cricket; a Brenthid beetle with a deep channel running along the dorsal part of the prothorax and occupied by achari; and an Anthribid beetle with a crescentic sulcus on the prothorax. All the specimens were from British North Borneo.—Mr. C. J. **Gahan**, on behalf of Mr. C. O. Waterhouse, exhibited a living example of *Phaneroptera quadripunctata*, which species had been found in some numbers in a vinery near Chester.—Mr. W. J. **Kaye** brought for exhibition a long variable series of *Heliconius numata* from the Potaro River, British Guiana, clearly proving that these very variable forms were only aberrations, and not a subspecies, at least in this locality.—Mr. A. H. **Jones** exhibited a collection of Lepidoptera made by him in Majorca during the first half of last June, and remarked upon the great scarcity of lepidopterous life in the island. Only thirteen species of butterflies were observed, all of the commonest kinds and without any indication of variation, with about six species of moths (all occurring in Britain), including *Agrotis saucia*, *Acidalia ochrata*, and *A. degeneraria*, the latter, interesting in point of colour, being much redder. Mr. Jones also exhibited *Melanargia lachesis* var. *canigulensis* from Le Vernet, showing on the under side in the males a strong resemblance to *M. galathea*, and *Melitaea aurinia* var. *iberica*, Obth., from Montserrat, near Barcelona, and a melanic specimen of *Erebia stygne*, taken by Mr. R. S. Standen last June at St. Martin du Canigou, Le Vernet.—Mr. F. P. **Dodd** communicated a paper on a parasitic Lepidopteron from Queensland, Australia.—Commander J. J. Walker read a paper by Mr. E. G. R. **Meade-Waldo** on a collection of butterflies and moths made in Morocco, 1900–01–02. The species enumerated included a Cœnonympha and a Satyrus new to science. But for so luxuriant a country as that visited it was remarkable how few butterflies and moths were observed.

Royal Microscopical Society, October 18.—Dr. Dukinfield H. Scott, F.R.S., president, in the chair. An old Wilson screw-barrel simple microscope, date about 1750, presented by Major Meade J. C. **Dennis**. The secretary traced the history of microscopes' focusing by means of a screw cut on the body-tube from Campani in 1686, Grindl in 1687, Bonanni in 1691, Hartsoeker in 1694, to Wilson in 1702, who was followed by Culpeper somewhere before 1738 and Adams in 1746.—A simple portable camera for use with the microscope: E. **Moffat**. The arrangement comprised a vertical telescopic standard, drawing out to 28 inches, having a clamp at the lower end for securing it to the edge of a table. At the upper end was fixed a mahogany board $\frac{3}{4}$ inch thick by 4 inches by 5 inches, hinged at the pillar so as to close up, and having a hole in the centre about 3 inches in diameter. There were two spring clips for securing the dry plate while making the exposure, and guides for keeping it in position horizontally. The back of the dry plate was covered by a piece of cardboard painted dead black, the spring clips referred to pressing upon this card. Depending from the board was a tapered bag of black Italian cloth about 17 inches in length, with a rubber ring at the lower end to secure the covering to the eye-piece of the microscope. The apparatus can be closed up into a space 5 inches by 9 inches by $1\frac{1}{2}$ inches, and will go into a large pocket or knapsack. The weight, if made of aluminium, should not exceed $1\frac{1}{2}$ lb. It will work well up to 700 diameters, and can be made in brass for 21*s*. Aluminium would cost more.—A form of hand microtome devised and used by Mr. **Flatters**. The microtome was made of brass, having the tube 3 inches deep and 1 inch diameter inside. The spindle had twenty-eight threads to the inch, and had a notched disc at the lower end, acted on by a spring stop the tension of which could be adjusted. Three discs were supplied, permitting sections being cut of 1/2000 to 1/1200 inch in thickness for each notch that the disc was turned. The knife-plate was made of *hardened* brass, the aperture on the under side being of the same diameter as the tube, but somewhat less on the upper side to prevent the specimen turning.—The Finlayson "comparascope": Messrs. R. and J. **Beck**. The president said they had the instrument before them some time ago in a less developed form; it seemed likely to be extremely useful to microscopists, as it could be applied to any microscope, and afforded a ready means of comparing objects directly under conditions which rendered it possible easily to detect slight differences.—Notes on aragotite, a rare Californian mineral: Prof. Henry G. **Hanks**. The mineral, which is a hydrocarbon, was first described by Mr. F. E. Durand in a paper read by him before the California Academy of Sciences on April 1, 1872. It was not until 1893 that Prof. Hanks obtained specimens of the mineral. These he subjected to various experiments, and disputes Mr. Durand's conclusion that it might be some modification of idrialite. He gives a table showing that in chemical composition, colour, streak, hardness, and specific gravity aragotite differs from idrialite.

PARIS.

Academy of Sciences, October 25.—M. Troost in the chair.—Some facts concerning the history of emulsin; the general existence of this ferment in the Orchidaceæ: L. **Guignard**. The examination of various parasitic plants showed the constant presence of emulsin; it would appear that there is a constant relation between the presence of this ferment and parasitism. On further work, however, this was not found to be the case, since a careful examination of *Orobanche Galii* and *O. Epithymum* gave no emulsin. Numerous plants of the Orchidaceæ, both indigenous and exotic, proved to have emulsin in their aërial and subterranean roots.—On the decapod Crustacea collected by the yacht *Princesse Alice* in the course of the voyage of 1905: E. L. **Bouvier**.—Report on a memoir of M. Bachelier on "continued probabilities": H. **Poincaré**.—Observation of the eclipse of the sun of August 30: F. **Jehl**. The observations were made at the Observatory of Aosta (Italy) under excellent atmospheric conditions, and included the times of contacts, visual observations of the spectrum, and temperature changes.—On discontinuous groups: Frédéric **Riesz**.—Researches on gravitation: V. **Crémieu**. The experiments described show the possibility of carrying out the Cavendish experiment in a liquid. Full details of the arrangement of the apparatus are given, but the publication of the results is reserved for a later paper.—On the specific inductive power of benzene and water: F. **Beaulard**. L. Grætz and L. Fomm have pointed out the existence of a phenomenon of polarisation which is in contradiction with the fundamental hypothesis of Poisson-Mossotti, and this relation has been utilised by the author as the basis of his method of measurement. The specific inductive powers thus found were 1·657 for benzene and 11·04 for water.—On the specific heat of solutions of copper sulphate: P. **Vaillant**. The solutions were heated by an incandescent lamp, the current and electromotive force being measured directly. If the specific heat of solution be regarded as the sum of that of the solid copper sulphate and water, negative values are obtained, but this is not the case if the substance in solution be regarded as $CuSO_4.5H_2O$. Even on this assumption constant values are not obtained for the specific heat, and several possible explanations are put forward.—

On the composition of the hydrochloroferric colloid as a function of the amount of HCl in the liquid: G. **Malfitano.**—On some aromatic ethylene oxides: MM. **Fourneau** and **Tiffeneau.** A study of the conditions under which the ethylene oxides tend to pass over into aldehydes.—New researches on the development of green plants: Jules **Lefèvre.** The author's experiments lead to the same conclusion as those of Moll and Cailletet, if carbonic acid is absorbed by the roots it is not utilised by the plant.—An analysis of some anthropometric measurements of men and women of the gipsies: Eugène **Pittard.**—Serotherapy in cases of bleeding: Émile **Weil.** In the cases known as "bleeders," in which a slight wound continues to bleed, it is shown that this effect is due to a property of the blood itself. This disease can be remedied by the injection of normal human or bovine serum. Details are given of the cure of one case, who, on the twenty-fifth day after the last injection, for the first time in his life, had a tooth removed with only the normal loss of blood.—The distribution of fine sediment on the bed of the ocean: J. **Thoulet.**

NEW SOUTH WALES.

Linnean Society, August 30.—Mr. T. Steel, president, in the chair.—Crustacea dredged off Port Jackson in deep water: F. E. **Grant.** Six species of Malacostraca were taken, of which four species, referable to the genera Hyastenus, Cymonomops, Latreillopsis, and Paguristes, are described as new. Of the remaining two species, *Ebalia tuberculosa* and *Ibacus alticrenatus,* only the former has previously been recorded as belonging to our fauna.—Notes on Prosobranchiata, No. 4, the ontogenetic stages represented by the gastropod protoconch: H. Leighton **Kesteven.** The present contribution is a continuation of the writer's attempts to unravel the puzzles presented by the gastropod protoconch. He finds that he is able to define four stages of growth represented, and supposes an "ideal" protoconch to be composed of (1) the "plug" of the primitive shell gland; (2) a portion formed by the veliger; (3) a portion formed during the nepionic stage; and finally (4) a portion formed during early neanic stages.—On a new species of Eucalyptus from northern New South Wales: J. H. **Maiden.** This is a large white gum, much resembling the blue gum (*E. saligna*) when growing, and the timber of which is specially esteemed. Its timber, however, as compared with that of *E. saligna,* is white from the sap to the heart. Its closest affinity appears to be with *E. Deanei,* Maiden.—A gelatin-hardening bacterium: R. Greig **Smith.** The bacterium was isolated from the tissues of *Schinus molle,* which was exuding a turquoise coloured gum-resin. When it was grown upon ordinary glucose gelatin, the medium became deep brown in colour, and was not liquefied when heated to the boiling point of water. Tannin, formaldehyde, or oxidising enzymes could not be detected.—On the supposed numerical preponderance of the males in Odonata: R. J. **Tillyard.** Reasons are given for concluding that the ratio of the numbers of the sexes in the dragon-flies or Odonata is a ratio of equality. The idea of the preponderance of the males, suggested largely by the examination of collections, and voiced from time to time by naturalists, has not been confirmed by experience in rearing a large number of nymphs of *Lestes leda.*

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 2.

CHEMICAL SOCIETY, at 8.30.—Solution and Pseudo-solution, part iv., Some of the Arsenious Properties of Arsenious Sulphide and Ferric Hydrate: E. Linder and H. Picton.—The Molecular Conductivity of Water: P. Blackman.—The Stereoisomerism of Substituted Ammonium Compounds: H. O. Jones.—The Influence of very Strong Electromagnetic Fields on the Spark Spectra of Ruthenium, Rhodium, and Palladium; J. E. Purvis.—Note on the Fluorides of Selenium and Tellurium: E. B. R. Prideaux.—The Constitution of Glutaconic Acid: J. F. Thorpe.—Some Alkyl Derivatives of Glutaconic Acid and of 2:6-Dioxypyridine: H. Baron and J. F. Thorpe.—Note on the Formation of β-Methylglutaconic Acid and of αβ-Dimethylglutaconic Acid: F. V. Darbishire and J. F. Thorpe.

LINNEAN SOCIETY, at 8.—Plant Ecology, interpreted by Direct Response to the Conditions of Life: Rev. G. Henslow.

RONTGEN SOCIETY, at 8.15.—The Ruhmkorff Coil: Prof. Wertheim-Salomonson.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Sea Defences: Baron H. T. H. Siccama.

FRIDAY, NOVEMBER 3.

GEOLOGISTS' ASSOCIATION, at 8.—Conversazione.

MONDAY, NOVEMBER 6.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Introductory Remarks: The President, Sir George D. T. Goldie, K.C.M.G., F.R.S.—Travels in the Mountains of Central Japan: Rev. Walter Weston.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Evaporation *in vacuo* of Solutions containing Solids: Dr. J. Lewkowitsch.

WEDNESDAY, NOVEMBER 8.

GEOLOGICAL SOCIETY, at 8.

THURSDAY, NOVEMBER 9.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting.—The Continuum and the Second Number-class: G. H. Hardy.—On the Arithmetical Nature of the Coefficients in a Group of Linear Substitutions of Finite Order (second paper): Prof. W. Burnside.—On the Asymptotic Value of a Type of Finite Series: J. W. Nicholson.—On an Extension of Dirichlet's Integral: Prof. T. J. I'A. Bromwich.—(1) On Improper Multiple Integrals; (2) On the Arithmetic Continuum: Dr. E. W. Hobson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Inaugural Address: John Gavey, C.B.

FRIDAY, NOVEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY, at 8.

MALACOLOGICAL SOCIETY, at 8.—(1) Descriptions of New Species of Drymæus, Amphicyclotus, and Neocyclotus from Central and South America; (2) Description of a New Species of Achatina from Mashonaland: S. I. Da Costa.—On a Collection of Land and Freshwater Shells from Sumatra with Descriptions of New Species, part i.: Rev. R. Ashington Bullen. On a New Species of Oliva: F. G. Bridgman.—On the Anatomy of *Ensis macha* and *Solen fonesii* and *S. viridis*: H. H. Bloomer.

CONTENTS.

THURSDAY, NOVEMBER 9, 1905.

STRENGTH OF MATERIALS.

Mechanics of Materials. By Mansfield Merriman. Tenth edition, re-written and enlarged. Pp. xi + 507. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 21s. net.

THE great development of engineering schools in the United States has led to the production of a considerable number of technical text-books primarily intended for students. It may at once be stated that, taken as a whole, these books are increasingly scholarly and sound; but they are largely compiled from similar European text-books, and often disclose a want of any serious independent investigation of the subject dealt with.

The present book is in some respects an excellent treatise, and as it has reached a tenth edition it must have been found useful. It deals with the elastic and, to a limited extent, with the plastic properties of materials of construction and the application of the laws of strength of materials to the simpler machine parts and structures. The treatment is essentially theoretical, and the book must be judged by the way in which it presents theory to students. The first point which strikes a reader is the great looseness of terminology. In the first two or three pages tension, tensile force, pull and axial force are all used as equivalent, which may not be wrong, but is confusing. Also a compression is a shortening, a sliding (in shear) is a detrusion, and the word strain does not appear in the volume, which is unusual. Young's modulus is termed throughout *the* modulus of elasticity; the condition that lateral contraction is unhindered is not explained. The coefficient of rigidity is referred to (p. 38) as the "modulus of elasticity for shear," but the relation of E and G is not discussed until p. 465. The volumetric modulus is described on p. 467, but these are the only elastic coefficients mentioned.

The author has an aggravating way of describing a thing at first very crudely and inaccurately, but without any reservations, giving a revised statement much later on and a further revision later still, and this in the case of quite simple matters. Take, for instance, the treatment of shear. On p. 38 the author takes as the typical example of shear a force P acting at the end of a T-shaped short beam. This is, of course, a case of shear and bending, and the rectangular elevation of the beam would not become a rhombus as the author states. The shear on horizontal planes is not referred to, and the unit stress is given as P/a without any caution that it is not uniformly distributed; and it is from this complex case that he deduces, as if it were a simple shear, the coefficient of rigidity. All this is inaccurate and confusing to students. It is not until p. 264 that it is explained that shear on one pair of planes is accompanied by an equal shear on a pair of planes at right angles, and on p. 465 the author goes back to representing shear as a single couple on a pair of parallel planes. In both Figs. 15 and 181 the deformation is so drawn that a student would infer a change of volume in shear, and nowhere, so far as can be found, is the constancy of volume in shear referred to. On p. 14 the end of a beam strained by a couple is used as an illustration of shear. The unit shearing stress is given as P/a, which is only the mean stress, and it is added that the bar will shear off when P/a is "equal to the ultimate shearing strength of the material," which is not the case. Can a more misleading statement for a student be imagined than (p. 14) "tensile and compressive stresses usually act parallel to the axis of a bar, but shearing stresses at right angles to it"? or this statement, p. 363, "it is best to consider shear as a signless quantity"? All these matters are elementary, and they are not so much wrong as slovenly and confusing—and similar faults occur constantly.

When the elastic limit is exceeded, the strains increase faster than the stresses. "Therefore the elastic properties of a bar are injured when it is stressed beyond the elastic limit." It would not be exact, but it would be more accurate, to say that the elastic properties are improved by straining beyond the elastic limit. "Accordingly it is a fundamental rule that the unit stresses should not exceed the elastic limit." The large deformation in ordinary materials beyond the elastic limit is the primary reason for limiting stresses to the elastic strength. It would be undesirable for a bridge to deflect several feet. The elastic limit is always assumed by the author to be a definitely fixed stress, and its variation under variation of loading is never referred to.

"The stresses are usually computed for dead and live loads separately regarding each as a static load. The live load, however, really produces greater stresses than the computed ones."

The live load undoubtedly may cause rupture when an equal dead load would not, but the author's statement is extremely doubtful, and the question is one of the most fundamental in applying the rules of strength of materials, and should on no account be slurred over in a text-book. The account of Wöhler's fatigue experiments (p. 352) is very brief and imperfect. American bridge builders have never fully accepted Wöhler's results, and have been disposed to explain the smaller working stress in members subject to great variation of stress as justified by the effect of impact. Practically it does not matter much whether the reduction of the working stress is termed an "allowance for impact" or "an allowance for fatigue," but it is a fundamental point, and the author's treatment of it on p. 358 will not much help a student. The author's theory that a live load produces more stress "because it is applied quickly," and the statement that the dynamic stress T can be expressed in terms of the static stress S by the relation $T = \phi(t)S$, where $\phi(t)$ is a function of the time of application, will require much more investigation before it is accepted. The effect of variation of stress in inducing fatigue, the effect of impact or of loads which have kinetic energy before deformation begins, and of loads which are unbalanced so that they acquire kinetic energy during deformation, require

careful discrimination. The effects should not be lumped together as due to suddenness.

A good deal of space is devoted to what the author terms "true stresses." He takes the well known strain equations $E\epsilon_1 = S_1 - \lambda S_2 - \lambda S_3$, &c., and, because $E\epsilon_1$ is of the same form as stress in terms of extension, he calls $E\epsilon_1$ the "true stress" due to the "apparent stresses" S_1, S_2, S_3. This is to use the term "stress" in a totally new sense. The real stresses which balance the external forces are only "apparent stresses"; an imaginary stress which is greater is the "true stress." It is impossible here to follow the author to the curious results he arrives at, which involve a revision of all the ordinary formulas of strength. It is not difficult to see from what point he has drifted. He throughout implicitly assumes that the condition of security in a structure depends on the maximum stress. He nowhere discusses the other views which have been taken. Now one of these is that security depends, not on maximum stress, but on maximum strain. What the author does with his equations is to make security depend on the maximum strains ϵ_1, &c.; but this does not justify him in calling $E\epsilon_1$ a true stress.

A HANDBOOK OF FLOWER BIOLOGY.

Handbuch der Blutenbiologie. Vol. iii. Part ii. By Ernst Loew, assisted by Otto Appel, completing the work commenced by Paul Knuth. Pp. v+601. (Leipzig: Wilhelm Engelmann, 1905.) Price 18s. net, in paper cover.

THE work which the late Prof. Knuth projected and commenced a "Handbook of Flower-Biology," to replace Hermann Müller's "Fertilisation of Flowers" is now complete. It runs as follows:—vol. i., an advanced text-book of flower biology; vol. ii., an account of observations made in Europe (two parts); vol. iii., an account of observations made outside Europe (also two parts).

Ernst Loew, who, after Knuth's death, undertook the completion of the work, appends to the last part a review of the collected extra-European observations.

There can be no doubt of the preeminent fitness of Dr. Loew for his task; but the result on close criticism is found just a little disappointing on account of omissions, *e.g.* Willis's observations on Phacelia, Monarda, and Ixora, and Keeble's on Loranthus, incorrect citations at the rate of one per page in the literature-list—an imperfect index, far too many printer's errors, and illustrations not always, I believe, drawn from the living flower.

Dr. Percy Groom (NATURE, vol. lxxi. p. 26) remarked on omissions and printer's errors in reviewing the preceding part of this work.

Of the body of the work, it is to be said that, besides abstracting all pertinent publications that have fallen into Dr. Loew's hands, it gives to the world a considerable number of original observations made by Knuth in Java, Japan, and California, and a few of Loew's made in the Berlin Botanic Garden, and that the names of North American insects have been subject to a revision by Prof. Robertson, of Carlinville, Illinois.

Of the review, it is to be explained that it centres on a discussion of the fertilising agents in countries outside Europe. I greatly appreciate the vast amount of labour which Dr. Loew has put into it. He could hardly have made greater use of the fragmentary material to hand. But the account of fertilisation in the tropics wants atmosphere; it is such as a man would write who had no particular experience of their vegetation. Twelve pages of the review are given to this account: first, Dr. Loew borrows from Prof. Warming a description of the vegetation of Lagoa Santa, in Brazil; then he goes on very successfully to discuss the part which birds play in fertilising flowers. In the place of the description of Lagoa Santa, one had hoped to find a more general description of tropical seasons. Nearly twelve pages are given to an account of fertilisation in New Zealand and the Antarctic islands—chiefly to a comparison of Arctic and Antarctic flowers, wherein Loew sees less agreement than does Delpino. Four and a half pages are given to South Africa with Madagascar—an ill-assorted union, three to the cactus region of N. America, six to the Arctic region including Spitzbergen, and twenty-six to the forest belt of N. America. I have here set down the number of pages devoted to each region because they rightly indicate the proportion in which the regions have been studied.

In dealing with the forest belt of N. America, Loew depends, of course, on Robertson's excellent work; there alone he really finds facts enough to enable him to work in the statistical methods which he has used so extensively in his writings regarding European flowers.

A time will come when the botanists of North America ask for a handbook of North American flower biology. Loew's work shows how far from readiness is material for it, and how very much further from readiness is material for a handbook of flower biology for any other part of the world. Until we get such handbooks, Loew's volume of Knuth's work will remain very useful on account of its suggestions, its references, its information, and especially as a companion in travel. I. H. B.

A FRENCH BOOK ON SPORT AND TRAPPING.

Chasse, Élevage et Piégeage. By A. de Lesse. Encyclopédie Agricole. Pp. xii+532; illustrated. (Paris: J. B. Baillière and Son, 1905.) Price 5 francs.

THE volume before us is one of a series dealing not only with subjects pertaining to agriculture in its proper and more restricted sense, but likewise with practically everything connected with country life which has any bearing at all on that pursuit. In the present instance, the subject of the trapping and snaring (*piégeage*) of animals, which, in the case of noxious species is, of course, a matter of considerable importance to the agriculturist, serves to establish a connection between sport (especially in the French sense of that term) on the one hand and agriculture on the other, and thus justifies the inclusion of the volume in the series. In connection

with the subject of trapping and snaring, we may take occasion to remark that the agitation which has been set on foot in this country against traps of an unduly cruel nature (indeed, against "gin-traps" of all kinds) does not appear to have reached the other side of the Channel, or, at all events, does not seem to have had any effect there. For in the present volume there is a cut of an unfortunate falcon ensnared in one of the abominable pole-traps, without a word of condemnation of snares of that description (unnecessarily cruel from the fact that they are in many cases only visited at long intervals).

The volume commences with a series of chapters pointing out the commercial importance of "la chasse," first as a source of revenue to the State, then as a source of food-supply, next in connection with rendering unfertile tracts profitable, and finally in relation to the rural population. The second section of the volume is devoted to game protection and the natural and artificial rearing of game birds, in the course of which the English and French methods of pheasant breeding are contrasted and their relative merits compared. Sporting dogs—other, of course, than hounds—form the subject of the third section, which is illustrated with a number of cuts (not by any means always of the best) of some of the chief breeds, and the manner of training dogs for their special duties. Then comes a dissertation on the various methods of destroying animals commonly classed as injurious to the game-preserver and the agriculturist, in the course of which, as already mentioned, every kind of trap and gin, no matter how cruel, is described in detail, while the reader is also instructed in the various methods of employing fire-arms and poison for the same end. The more legitimate forms of sport, including, however, small-bird-shooting and rabbit-netting, together with an account of the legislation connected with the subject, form the concluding sections of the volume. The whole subject of "la chasse" or "le sport" is viewed so differently by our French neighbours and by ourselves, that it is somewhat difficult to give an unbiased opinion on the merits of the volume before us. Probably, however, it is thoroughly well suited to the class of readers for whom it is specially intended, although we cannot but regret that an attempt was not made to inculcate more humane views in the matter of the destruction of so-called noxious animals.

R. L.

OUR BOOK SHELF.

Ergebnisse und Probleme der Elektronentheorie. By Prof. H. A. Lorentz. Pp. 62. (Berlin: J. Springer, 1905.)

THIS book contains a lecture given by Prof. H. A. Lorentz before the Elektrotechnischen Verein at Berlin, December, 1904, to which certain additions have been made. It is a most interesting semi-popular account of the present position of the electron theory, which is due largely to the author.

The lecturer begins with a short historical introduction, and then goes on to discuss the properties of kathode rays, which, of course, are negative electrons. He describes the methods by which the ratio of the mass to the charge of these rays has been determined, and Kaufmann's beautiful research on the β rays from radium, which, in conjunction with J. J. Thomson's and Abraham's theoretical investigations, has led to the conclusion that the mass of these rays or electrons is entirely electromagnetic in its origin.

The most interesting part of the lecture now follows, where a description is given of the electron theory of the conductivity of metals. The beginnings of the electron theory of metallic conductivity we owe to Weber and Kohlrausch, and its recent developments to Riecke, Drude, and J. J. Thomson. Lorentz here adopts J. J. Thomson's view, that the conductivity of metals is entirely due to the presence in them of freely moving negative electrons, and that the positive electrons are practically fixed, and so do not contribute to the conductivity. Riecke and Drude have so far supposed that both the positive and negative electrons move. The lecture contains an interesting discussion of the special difficulties of these rival hypotheses, neither of which has yet been made to fit in with all the facts.

According to the electron theory of metallic conduction, the electrons move about between the metal atoms so that they are practically in the gaseous condition and the results of the kinetic theory of gases can be applied to them. On these assumptions the ratio of the conductivity for heat to the electrical conductivity can be calculated, and the result is that

$$\frac{k}{\sigma}=\frac{4}{3}\left(\frac{\alpha}{e}\right)^2\mathrm{T},$$

where k=heat conductivity, σ=electrical conductivity, T=absolute temperature, e=charge carried by one electron, and α=the gas constant. According to this equation, k/σ should be the same for all metals and proportional to the absolute temperature. The experimental results so far obtained agree on the whole very well with these conclusions, and form a striking confirmation of the general truth of the theory. The observed absolute value of k/σ also agrees fairly well with that calculated by means of the formula just given.

The electron theory also gives a fairly satisfactory explanation of the phenomena of thermoelectricity and contact potential difference, but it is very difficult to reconcile completely with the facts on the Hall effect. H. A. Lorentz's lecture shows that many problems of the electron theory still await a solution, but it also shows the immense progress which has recently been made, and suggests the idea that very soon nothing but ether and electrons will be retained in our conception of the physical universe.

H. A. WILSON.

Die elektrischen Bogenlampen, deren Prinzip, Konstruktion und Anwendung. By J. Zeidler. Edited by Dr. G. Benischke. Pp. x+143. (Brunswick: Friedrich Vieweg und Sohn, 1905.) Price 5.50 marks.

THE book published under the above title forms the sixth pamphlet of "Elektrotechnik in Einzel-Darstellungen." The author divides the contents into four parts. In the first one he shows great ingenuity in classifying lamps; he also explains the actions of series, shunt, and differential arcs, and describes the precautions which are necessary to ensure steady burning.

In the second part we find the constructions of various types of arc lamps, the sizes of carbons to be used, the advantages and disadvantages of flame and enclosed arcs, and an article on inverted lamps.

The third part deals with the distribution and calculation of light. It describes the construction of polar and Rousseau curves, the meaning of hemispherical intensity, the power-factor of alternate current flame

arcs, the calculation of light for interior and exterior places, and concludes with tables giving the reflecting powers of various surfaces, and the horizontal illumination required for different places.

The last part illustrates the construction and application of auxiliary plant, including steadying resistances, choking coils, transformers, safety appliances, &c.

The book is intended chiefly for students. As such it might be improved by including a little more of the theory of the arc, of which the author says practically nothing. Very few engineering students will find sufficient time to study works such as "The Electric Arc," by Mrs. Ayrton, unless they make the study of arc lamps their speciality.

The second part will form a good advertisement for the A.E.G. Company's lamps, as most of the diagrams represent designs made by this firm. But although it is quite easy to deduct the principles of action of other lamps from the diagrams given, one does not like to see in a text-book the productions of one manufacturer only, as it reduces the work almost to a catalogue. Of great interest is Foster's hot-wire arc lamp, although its commercial value has yet to be proved.

The most useful part of the book is the third one, which will be welcomed by many students who are able to read German. Also the fourth part contains much useful matter.

The book is practically free from printer's errors. The few which occur may easily be detected by even the most elementary reader.

Taken as a whole, the pamphlet will be found a useful addition to electrical engineering literature.

H. BOHLE.

Transactions of the South African Philosophical Society. Vol. xv. Part v. Catalogue of Printed Books, Papers, and Maps relating to the Geology and Mineralogy of South Africa to December 31, 1904. By Miss M. Wilman. Pp. 283–467. (Cape Town, 1905.) Price 12*s*. 6*d*.

THIS excellent bibliography represents months of patient labour spent on a bewildering but necessary task, and now happily carried to a successful termination. The whole civilised world appears to have had something to say on African geology. The labour entailed in drawing up these lists, which easily supersede all others, will therefore be obvious. The author has had, indeed, to exercise considerable acumen in discarding numerous papers, &c., often containing mere references to geology, in order to bring the lists even within their present compass. As it is, a few works, since they are mentioned in earlier lists, have had to be included, although they add little to geological literature. The title is generally sufficient to warn the inquirer.

Part i. deals with works on the general geology of South Africa, part ii. contains a list of geological maps, while part iii. is exclusively devoted to works on meteorites. The print is clear, and the names of authors are distinctly marked in Clarendon type.

W. G.

Problems in Practical Physics. By F. R. Pearson, M.A. Pp. 30. (Edinburgh and London: Oliver and Boyd, 1905.) Price 6*d*.

THESE problems are intended to accompany practical work in a laboratory, and should serve to give practice in working out results. The subjects on which examples for solution are set include the parts of physical science studied in a first year's course. Teachers of mathematics may find the booklet useful, as it will provide interesting applications of simple mathematical principles to practical problems coming within simple laboratory experience.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Terminology in Electro-physiology.

MY attention has been directed to a letter in your columns (p. 5) commenting upon the ambiguous use made in physiological literature of two opposed terms, "negative" and "electropositive."

To me also it seems a misfortune that this ambiguity has ever arisen, nor do I see any necessity why it should be allowed to persist. There is no obvious reason why, in scientific papers, the terminology of the physicist should not be adhered to. The "negativity" of a point is detected by means of the current which flows towards it, or tends to flow towards it, through some form of external indicator connecting it to the point which is spoken of as "positive." These terms, and these terms alone, adequately express the facts of all the experimental observations made. Any other terminology differing from this is necessarily based upon some inference as to the mode of causation of the currents detected. Since it is the causation of these currents which is the main crux of the research work undertaken in this subject, the admission of such an inference seems a certain road to the confusion of ideas.

In all cases where an effort has to be made to carry home to an audience the more exact ideas existing in the author's brain, in all cases where parables are not only admissible but necessary, I think the terms suggested by Dr. Waller are of extreme value. Anyone acquainted with the explanatory use he has made of them in his "Animal Electricity" will agree. Whilst sincerely admiring his profoundly clever method of administering large doses of knowledge by means of this and similar parables, I have observed two things. In the first place, that duller wits, hugely mistaken, sometimes assess his knowledge as mainly one of parables. In the second place, that less expert persons are apt to carry conclusions derived from parables to a bitter and unjustifiable extremity.

Sheffield University. J. S. MACDONALD.

The Leonid Meteors, 1905

THE remarkable displays of these meteors observed in 1903 and 1904 may naturally raise the expectation as to whether the approaching Leonid epoch will exhibit an abundant fall of shooting stars. Observers, it is true, will have to contend against the impediment offered by the light of the gibbous moon; but, it may be remarked, this can only affect the smaller class of meteors, as the brilliant apparitions of 1866, 1867, and 1886 were witnessed at a similar phase of our satellite.

The Leonid events of the past two years afford striking illustrations of the meteoric cycle of nineteen years, being associated respectively with the Leonid meteor displays of 1865 and 1866, and the present November gives ample promise of furnishing another example of the same period.

Unlike the Leonid falls of 1865 and 1866, that of November 14, 1867, was brilliantly reproduced on the first completion of this cycle on the morning of November 15, 1886, the spectacle being of extraordinary splendour (NATURE, vol. lxi., p. 491).

The Leonid maximum of 1905 will fall on the night of November 15, and, according to calculations by the present writer, will be visible both over Europe and America. The shower will be of second-class order, that of 1866 being regarded as of first, and will commence early in the night, the first maximum occurring on November 15 11h. G.M.T. From this hour up to about three o'clock on the morning of November 16 the Leonids will probably gradually increase in numbers, the second maximum of the night becoming due on November 15, 15h. 10m. The final maximum on November 15 occurs at 21h., and will consequently be visible to American observers only.

Dublin. JOHN R. HENRY.

Border occasionally seen between Light and Dark Regions on Photographic Plates.

THE reason mentioned by Sir Oliver Lodge (p. 5) for the border seen between light and dark regions on photographs is not the only one. In the denser regions of a negative the developer gets more exhausted or restrained than in the thinner regions, and this affects the adjacent parts. At the junction of a dense and a thin area the edge of the thin part is made thinner by the restraining compounds (bromide, oxidised pyrogallol, &c.) derived from the denser part, while, on the contrary, the edge of the denser part is made denser by the less exhausted developer flowing from the thin area. This effect is apt to be the more marked when the developer is already well restrained, as by staleness or the addition of much bromide.

Cambridge, November 4. F. J. ALLEN.

THE explanation of a well known phenomenon in photography, given by Sir Oliver Lodge in his letter to you last week (p. 5), does not take into consideration the following facts:—

(1) The "perceptible difference in thickness" between the acted-on and unacted-on portions of a negative is only perceptible to our unaided senses when certain developers are employed containing substances which act powerfully on the gelatin. Most modern negatives certainly have no *perceptible* difference in thickness, certainly not enough difference to give rise to so marked an effect as that referred to.

(2) The difference in thickness is most marked in the "carbon" transparencies from which many enlarged negatives are made. Here it can be both seen and felt; in the other case it cannot. We might therefore expect this cylindrical lens effect to be most marked when using such a transparency, but the careful comparison of a number of enlarged negatives made in these two methods reveals not the slightest difference between them.

In my own mind I have always accounted for the phenomenon in the following way:—The sensitive film ordinarily can only be approached by the developer from its outward face, hence the action over an area where the light action has been the same is uniform. But if that area is bordered by one where there has been little or no light action, the developer absorbed by such parts is not spent in doing any or much work in those parts, and, so far as any lateral diffusion is concerned, is practically fresh developer. Hence the borders of an exposed portion, where it comes against an unexposed portion, are attacked by fresh developer diffusing both from the front and from the unexposed part, and we should therefore expect to find a border line of greater density there, as in fact we do. For a similar reason we should expect to find a less dense line on the border of the more transparent portion, as is the case, though it is not often so noticeable as the former.

That this is the true explanation is, I think, made manifest by the fact that the line in question can be quite easily distinguished on plates exposed in Spurge's actinometer, where there is certainly no opportunity of a "cylindrical lens effect," and especially when development has been pushed far. R. CHILD BAYLEY.

20 Tudor Street, London, E.C., November 6.

The Use of Gasoline in Chemical and Physical Laboratories.

EXPERIMENTAL work has so thoroughly established its claims to a reasonable share in the curriculum of every secondary school that very few schools are now without proper laboratories. No inconsiderable number of these schools are, however, beyond the limits of the ordinary gas supply, and the question of providing a substitute for coal-gas has presented no little difficulty. The matter became urgent some time ago at the Llanberis Intermediate School, mainly for heating purposes, but also for lighting. Investigation seemed to point to two possible substitutes—acetylene and gasoline. Both have been used, but not to any very large extent, in this country. An account was given in the *School World* for January 1902, of the use of acetylene in Felsted School.

For a small installation, where light is the first consideration, it would probably be admitted that acetylene is highly satisfactory, but even for lighting the use of mantles has rendered gasoline a very severe rival. The problem is different when heat is the chief factor. In most cases of schools the gas is required to meet both demands, and gasoline seems to possess the advantage.

The questions for consideration are cost and efficiency.

In reference to cost, estimates were obtained to supply the chemical and physical laboratories and to light the whole building, and showed that the initial cost of plant and fitter's work would be about fifty per cent. higher for acetylene than for gasoline, and the estimated cost of maintenance for the former was also much higher.

Efficiency may be considered under the following heads:—(*a*) The relative simplicity of the generating plant; (*b*) the ease of manipulation; (*c*) the nearness to which the gas approaches in use to coal-gas; (*d*) the risk of explosion.

(*a*) The plant used in the Llanberis School was supplied by the Walworth Manufacturing Co., of Boston, U.S.A., and consists essentially of three parts:—(1) A large shallow cylindrical copper tank, holding 250 gallons, buried some 30 feet or more from the building, which is filled with gasoline through a pipe and closed air-tight by a screw cap. Two other pipes, an inlet and outlet, are fitted into the top of the tank and pass under ground to the cellar of the building. (2) In the cellar a pump, worked by a weight on pulleys, forces air through the inlet pipe on to the surface of the gasoline in the tank. Evaporation is rapid (gasoline boiling from about 35° C. to 70° C.), and the mixture of vapour and air is driven through the outlet pipe into (3) an automatic mixer, by which a definite and known amount of air can be added, so that the proper proportion for burning may be constantly maintained. The whole plant is extremely simple, and was easily put up by a local gas-fitter under my direction.

(*b*) It requires very little attention. The weight has to be wound up about once a week; the mixer adjusted, by moving a small wheel along a rod, about once every two or three months; and the tank filled about every twelve or eighteen months. The frequency of the recurrence of these operations clearly depends on the size of the plant relative to the demands upon it.

(*c*) The burners differ slightly from the ordinary coal-gas bunsens, but give an excellent flame for ordinary laboratory purposes. The most noticeable difference is that the flame is more easily blown out. This gives a little trouble with an ordinary foot blowpipe, but a slight modification, which I hope to carry out, suggested by my friend Mr. B. B. Turner, of Storrs Agricultural College, Connecticut (who has used gasoline for some years, and who brought it to my notice), will probably get over the difficulty. The plant supplies enough gas to light the whole building as well as for laboratory purposes.

(*d*) The risk of explosion is very slight, as any escape is at once detected by the strong smell, and the limits of explosion are narrower than those of coal-gas and very much narrower than those of acetylene. The absence of any heating arrangements to aid the evaporation, such as are proposed by some makers, considerably reduces the risk of explosion. J. R. FOSTER.

THE AEGER IN THE RIVERS TRENT AND OUSE.

HAVING had an opportunity of witnessing the bore, or aeger as it is locally called, in the River Trent at Gainsborough during the recent high equinoctial tides, which did so much damage all along the east coast, I send you the following description, which may interest some of your readers, more especially as I am not aware of any trustworthy account of this bore that has yet been published.

The Trent is a tributary of the Humber, and joins that river about 16 miles above Hull and 40 miles from the North Sea. The width of the Trent at the junction is from 2500 feet to 3000 feet at high water, diminishing to 700 feet $1\frac{1}{2}$ miles from the

junction. This wide space is encumbered with a mass of sand banks. The width of the Humber below the junction averages about 4500 feet, and this channel also feeds the Ouse, which is a continuation of the Humber. This width is double that of the Trent and Ouse combined. The rise of ordinary spring tides at Trent mouth is 15 feet, increasing at equinoctial tides to 19 feet. The tide has a run of 47 miles up the Trent, and reaches to 87 miles from the North Sea, the flood lasting three hours and the ebb nine hours.

The bore, or aeger, is caused by the check of the tidal flow through the shoal water of the sand banks and the contraction of the waterway, the tidal current overrunning the transmission of the foot of the wave. It first assumes a crest somewhere between Burton Stather, 3 miles from the mouth of the Trent, and Amcotts, 2 miles further on, depending on the condition of the tide, the water rising almost simultaneously 3 feet. In ordinary spring tides the bore does not extend more than 7 or 10 miles above Gainsborough. In high spring tides it diminishes to 1 foot in height at Torksey, 35 miles from the mouth of the river, and then gradually dies out.

FIG. 1.—The Aeger in the Trent.

The bore was to be seen under exceptionally favourable conditions on September 30 and October 1 last, being the second and third days after the new moon. The tides were laid down in the Admiralty tide tables for the Humber as the largest of the year. The moon was in perigee on September 29, and had 11·21 degrees south declination. The wind was from N.E. to N.W., a direction which brings the largest tides, and was blowing at Spurn with a force of from 6 to 7. Inland the force was only about 3 on the Beaufort scale. There was a limited quantity of fresh water running down the river, the velocity at low water being 2 miles an hour. The depth in the channel between Gainsborough and the Humber is now about 6 feet, but there are several shoals with not more than 2 feet to $2\frac{1}{2}$ feet over them. The tide was exceptionally high, rising in the Humber at Hull nearly 3 feet higher than ordinary spring tides, and within 10 inches of the record tide of March, 1883.

The bore could be heard approaching about half a mile from the place of observation, and passed with a crest in the middle of the river of from 4 feet to $4\frac{1}{2}$ feet extending across the full width of the river, which is here about 200 feet at high water. At the sides the breaking wave rolled along the banks 6 feet or 7 feet high. The crest was followed by five or six other waves of less height, terminating in a mass of turbulent broken water for a distance of 100 yards. The velocity of the wave, as nearly as it could be measured, was about 15 miles an hour, the current running up after the bore had passed at the rate of $4\frac{1}{4}$ miles an hour, and at its maximum, about half flood, 5 miles an hour. The tide rose 4 feet in the first four minutes after the arrival of the bore, 5 feet in the first half hour, and 8 feet in two hours, when it attained its maximum height and commenced to fall; but the tide continued running up the river for another hour after this, at the reduced velocity of 2 miles an hour. There were some steamers and barges lying at the wharves, and a row-boat in the middle of the river. These rose with the wave and suffered no harm.

These bores were considered by the men on the river as fair specimens of those which come with high tides, and as never exceeded in height to any extent. When the river is full of fresh water and the ebb is heavy the bore is less pronounced, and does not show at all on neap tides. It was reported that at Owston Ferry, which is 8 miles nearer the Humber than Gainsborough, the crest of the aeger was 8 feet, but this was probably at the side of the river. A boat which was in the middle of the river when the wave came was for an instant completely out of sight of a spectator on the bank.

The photograph from which the illustration is taken is by Mr. E. W. Carter, of Gainsborough, and is copyright.

In the Ouse during spring tides there is a less pronounced bore. In ordinary spring tides it commences at a shallow reach in the river at Sand Hall, 2 miles above Goole, attains its greatest height 4 miles above Selby, and then gradually dies out. The crest of the bore is from 2 feet to 3 feet, and the breaking wave at the sides 6 feet or 7 feet. In summer, when the ebb current is low, the aeger reaches Naburn with a crest 1 foot 6 inches high. Since the improvement of the channel of the river below Goole these aegers have become smaller.

W. H. WHEELER.

SURVEY OF THE SIMPLON TUNNEL.

WE have appreciated many of the difficulties the engineers encountered in the construction of the Simplon Tunnel and have offered our congratulations on the successful completion of the work. But the difficulties that have been most readily apprehended have been those arising from the outburst of water from the hot springs in the track, the high temperature, and the mechanical boring and removal of the rock. In the happy completion of a task of great magnitude, which at one time threatened to end in a catastrophe, people are apt to forget the onerous preliminary work necessary to set out the line of the tunnel, to arrange the gradient so as to provide not only for efficient drainage at either end, but to secure the continuity of the separate tunnels at the point of junction, and so render it possible to work simultaneously at both ends. We are therefore glad to see an article by Prof. C. Koppe in *Himmel und Erde* for August [1] bringing these matters forward, and making us familiar with the work which has

[1] "Die Vermessungs- und Absteckungs-Arbeiten für den Simplon Tunnel"

been so efficiently carried out by Prof. Rosenmund of Zurich.

Before the work of boring and perforation can be begun, there are three elements which have to be determined with an accuracy which must be greater in proportion to the difficulties of construction. These are the direction, the length, and the altitude above sea-level. Assuming that the places of entrance and exit of the tunnel have been marked by suitable pillars, the determination of these three elements begins; and that of the level is the least difficult, because the surveying engineer trusts to direct measurements. By the aid of accurate levelling instruments, it is possible to derive the difference in altitude of two stations 50 kilometres apart with no greater error than 3 cm. This is effected by the use of the levelling staff, which is read by means of an accurate level, the staff being placed vertically at two stations a convenient distance apart, and the sum of the differences of each pair of readings being taken. The surveyor apparently trusts entirely to the accuracy with which his theodolite can be levelled. Several determinations of the difference of level of the two ends of the tunnel were made, but between the two last there was a discrepancy of only 2 cm., a more than sufficient degree of accuracy. The actual difference of level between the two ends was 52.439 metres.

The second element, that of the length of the tunnel, is to be derived indirectly from triangulation, the length being reckoned from the same points that have served for the determination of difference of level, and, as a matter of fact, these points are at some distance from the actual openings. A base line being given, the construction and the solution of the triangles present little difficulty, for here great accuracy is not required, and the probable error that Prof. Rosenmund was content to leave in his work amounted to ±0.7 metre. The distances measured are as follows:—

	metres
The length between the columns marking the axis of tunnel...	20,091·33
Distance of northern column from tunnel opening	317·78
Distance of southern column from tunnel opening	44·84
Actual length of tunnel	19,728·71

The third element, that of direction, at all times presents some difficulty, and, in the case of mountains, where local attraction enters as a disturbing factor, the problem requires very delicate treatment. In a tunnel 20 kilometres long, an error in direction of one minute, which is usually the limit of accuracy sought in technical work, would produce an error of 6 metres, and the tenth part of such an error would be too great. Recourse is necessarily had to triangulation, and the angular measurements must be made with the greatest care. Well-defined signal posts must be erected to mark the angles of the selected triangles, and the points of reference in these pillars defined with the utmost accuracy. The form which Prof. Rosenmund preferred consisted of cylindrical towers of brick about eight feet high, of which the axis was an iron tube the upper edge of which reached the top surface of the tower. A wooden pole carried this iron tube vertically upwards, and the whole was surmounted by a conical tin covering, the highest point of which was vertically over the centre of the iron axis. Eleven of these piers were erected, and when signals were made from any pillar the conical top was removed, and the theodolite was placed centrally over the middle of the iron tube in the cylindrical tower, which afforded a solid support for the instrument and permitted accurate observation of the other stations. With the care exercised, it might have been anticipated that the sum of the angles of any triangle would differ from 180° by the known amount of the spherical excess, within the errors of observation. But the discrepancies were much larger, varying from 4 to 8.5 seconds, and these deviations could be explained only by attributing to the mountain an attractive force, which sensibly displaced the direction of the plumb-line. In other words, the theodolite was not placed horizontally. The amount of the deviations from the vertical, with the azimuths in which they occur, is shown in the following table:—

Station	Deviation from vertical	Azimuth
	″	° ′
North point of axis... ...	13·9 ...	248 26
Oberried	19·1 ...	195 12
Birgischwald	16·4 ...	188 5
Rosswald	23·6 ...	262 56
Spitzhorn	17·5 ...	314 18
Monte Leone...	0·0 ...	0
Hullehorn	8·2 ...	244 3
Seehorn	5·6 ...	75 28
Alpe Wolf	11·4 ...	36 46
Genuina	9·1 ...	192 3
South point of axis... ...	5·8 ...	139 11

Assuming these deviations from the vertical to arise from the attraction of the mountain mass, an hypothesis which was confirmed by rigorous astronomical observation, it was found possible to reduce the closing errors of the triangles very materially. The solution of the whole network of triangulation showed that the tunnel's axis was fixed with a probable error of ±0″.7, and that the direction of the tunnel could be fixed with sufficient accuracy by pointing the telescope, placed on one of the piers at the entrance of the tunnel, to any other signal tower, and revolving the telescope through a known angle.

It would be interesting to enter into the details by which the path of the tunnel was checked as the work progressed, more especially as curious refractive effects, akin to those seen in "mirage," occurred to render the observations somewhat difficult and uncertain. These disturbing effects were more noticeable when observing towards the north end of the tunnel, where the difference of temperature between the internal and external atmosphere was greatest. On the southern side, the external air being warmer than on the north side, the "mirage" was not so conspicuous. But we have only space to refer to the degree of success which resulted from the care bestowed on this difficult undertaking—a success which could not be adequately tested until the junction of the engineering parties in the middle of the tunnel was effected. To take the three elements in order, it was found that the level agreed within 0.1 metre of the calculations. The length as measured differed 2 metres from the calculated value, but, as mentioned, this was a factor in which great accuracy was not needed, because, if the direction were given correctly, it was only necessary to continue the borings until the engineers from the south and north sides met in the middle. The direction was most satisfactory. The wall of one tunnel was absolutely continuous with the wall of the other; an attempt was made to compare the opposite walls of the tunnel for confirmation, but this attempt was frustrated by a projecting piece of rock. No better result could have been anticipated, and the utmost credit attaches to Prof. Rosenmund and his assistants.

W. E. P.

BURSARIES AT THE ROYAL COLLEGE OF SCIENCE.

SCIENCE scholars selected from the whole of Great Britain for their ability and promise, maintaining themselves on 17*s.* 9*d.* per week, were this year saved from much privation by secret gifts of small bursaries—see the subjoined audited account. I have no right to ask for help from the generous men who helped me last year, but I have all the sturdiness of a chartered beggar—I ask in a good cause.

It was originally intended that these bursaries should be given only to such National Scholars as required assistance, but some of the subscribers have given me power to assist other students of the college. Also one of the two City Companies has given me power to grant an occasional bursary of more than ten pounds. It is understood that every student is morally bound to repay this money to the fund at some future time.

JOHN PERRY.

October.

ROYAL COLLEGE OF SCIENCE.

BURSARIES 1904–1905.

BALANCE SHEET.

Moneys Received and Paid by Prof. Perry.

RECEIVED	£ s. d.	PAID	£ s. d.
Balance from last year	£24 2 0	*Dec.* 16 *to Feb.* 28. 25 students received half bursaries, £5 each ...	£125 0 0
August, 1904. Dr. Sprague	20 0 0		
R. Kaye Gray, Esq..	10 0 0		
September, 1904. Prof. J. Perry (slide rules)	1 6 0	*January* 31, 1905. 1 student received a half bursary of £7 10*s.*	7 10 0
November, 1904. Returned half bursary	5 0 0		
Sir Andrew Noble...	10 0 0	*February* 15. 1 student received the second half of his bursary	5 0 0
December, 1904. The Drapers' Co. ...	100 0 0		
Prof. J. Perry (slide rules)	2 19 0	*March* 24 *to June* 15. 22 students received second halves, £5 each...	110 0 0
January, 1905. J. Drinkwater, Esq.	1 1 0		
The Goldsmiths' Co.	100 0 0	*June* 5. 1 student received second half ...	7 10 0
April, 1905. Prof. J. Perry (slide rules)	3 11 0	2 students refused their second halves	
		Balance in hand	22 19 0
Total	£277 19 0	Total	£277 19 0

Twenty-three students received 10*l.* each, two received 5*l.* each, and one received 15*l.*

Audited and Signed by JOHN W. JUDD.

Dated June 22, 1905.

DR. RALPH COPELAND.

ASTRONOMERS will have learned with profound regret that Dr. Ralph Copeland, Astronomer Royal for Scotland, died on October 27 at the Edinburgh Observatory in the sixty-eighth year of his age. Dr. Copeland enjoyed a more varied life than generally falls to the lot of astronomers. The love of travel and adventure seemed with him to be only second to his desire to advance the interests of astronomy.

Born in Lancashire, he early went to Australia, where, on the somewhat uncongenial soil of a sheep-run, he acquired his first telescope and diligently used it. Then he was for a short time attracted by the excitement of the gold diggings, but he forsook these to return to England, having determined to devote himself to astronomy. He matriculated at the University of Göttingen, and enjoyed the advantages of instruction from Prof. Klinkerfuss. For a while he took part in the routine work of the Göttingen Observatory, but the love of adventure still possessed him, and we find him in 1867 taking part in an expedition to explore the east coast of Greenland, climbing mountains and otherwise distinguishing himself, so that on his return he was awarded the Order of the Red Eagle by the German Emperor. Shortly after his return to Europe he came to England, and though he was connected with both the observatory of Lord Rosse at Birr Castle and with that at Dunsink, he is better known for his work in connection with both expeditions of 1874 and 1882 to observe the transit of Venus. In the first he was a member of Lord Lindsay's (now Earl of Crawford) unsuccessful expedition to Mauritius, but on the occasion of the second transit he was more fortunate at Jamaica. Before returning to England he spent some time in the Andes of Peru and Bolivia, at altitudes varying from 10,000 feet to 15,000 feet above sea-level, where he carried out a series of researches on the transparency of the atmosphere, the spectra of planetary nebulæ and of certain classes of stars.

In 1889, when the Earl of Crawford presented his instrumental equipment to the Edinburgh University, Dr. Copeland became regius professor of astronomy and Astronomer Royal for Scotland. Here his great work consisted in the re-construction of the National Observatory at Blackford Hill, the full development of the capacity of which was denied him by reason of his failing health. But he still enjoyed opportunities for foreign travel. Norway, India, Spain, were all visited in turn for the observation of solar eclipses. His favourite instrument on these expeditions was a telescope of long focal length.

Dr. Copeland's acquaintance with astronomical literature was wide and intimate, and his collection of works having reference to some departments, such as cometary astronomy, was probably unique for its completeness. In cometary observation he was particularly interested, and it will be recalled that for many years he gave valuable assistance to observers of comets by calculating and circulating ephemerides which he printed at a small press of his own. For some time he gave further encouragement to the science by editing, in conjunction with Dr. Dreyer, the periodical *Copernicus*, devoted to the publication of high-class papers. In fact, Dr. Copeland's activities were by no means limited to what may be called his official duties. He had the gift to interest by his varied knowledge and experience, and used it liberally. He was held in estimation by a large circle of friends and pupils for the picturesqueness with which he imparted his information and his readiness to assist and encourage. The writer is among those who will gratefully acknowledge the charm of his manner and the kindnesses received at his hands.

W. E. P.

CAPTAIN F. W. HUTTON, F.R.S.

NATURAL science has sustained a heavy loss in the death of Captain F. W. Hutton, curator of the Canterbury Museum, president of the New Zealand Institute, and formerly professor of biology and geology in Canterbury College, University of New Zealand. The second son of the Rev. H. F. Hutton, Rector of Spridlington, in Lincolnshire, Frederick Wollaston Hutton was born at Gate Barton in that county on November 16, 1836. He was educated at the grammar school at Southwell, and afterwards at the Naval Academy at Gosport. After serving for three years in the India mercantile marine he entered the Army, becoming ensign in the 23rd Royal Welsh Fusiliers in 1855. He served in the Crimea (1855–6), and saw further active service during the Indian Mutiny, being present at the capture and relief of Lucknow. He was made lieutenant in 1857.

In 1860 he furthered his military studies at the Staff College at Sandhurst, passing the examinations in 1861. At this date geology was taught in the Royal Military College by Prof. T. Rupert Jones, and Hutton, who had taken up the subject with enthusiasm, contributed in 1862 to the *Journal of the Royal United Service Institution* (vol. vi.) an essay on "The Importance of a Knowledge of Geology to Military Men." The importance, strange to say, does not appear to be so fully recognised nowadays. Hutton became captain in 1862, and served for a time as Deputy-Assistant Quartermaster-General at Dublin; but in 1866, having retired from the Army, he emigrated to New Zealand, and devoted himself to the study of natural history, and especially to zoology and geology. In 1871 he was appointed assistant geologist on the Geological Survey of New Zealand, in 1873 provincial geologist of Otago and curator of the Otago Museum, and in 1877 professor of natural science in the Otago University. In 1880 he settled at Christchurch, having become professor of biology and geology in the University of New Zealand, a post which he held until 1893, when he became curator of the Canterbury Museum at Christchurch. He was elected a Fellow of the Royal Society in 1892.

One of his earliest geological papers, a sketch of the physical geology of Malta, was published in the *Geological Magazine* (1866). From this date his work related mainly to the country of his adoption. He prepared official reports on the Lower Waikato district and on the Thames gold-field in 1867, and a report on the geology and gold-fields of Otago (with G. H. F. Ulrich) in 1875. To the Geological Society of London he contributed in 1885 an excellent sketch of the geology of New Zealand, which gave a comprehensive summary of the knowledge attained at that time, and in 1887 he sent to the same society an account of a recent eruption of Mt. Tarawera in North Island. He contributed many other geological papers to the Geological Society and *Geological Magazine*. While distinguished as a geologist, the importance of his researches on zoology was early recognised, and he was elected a corresponding member of the Zoological Society in 1872.

He contributed articles on the fauna and flora of New Zealand, on the land mollusca, the fishes, and the birds, including the extinct moas. Some of these articles were printed in the *Transactions of the New Zealand Institute*, the *Proceedings of the Linnean Society of New South Wales*, in the *Proceedings of the Zoological Society*, in *Ibis*, and other journals.

He was an ardent student of evolution, and among other works issued in 1899 "Darwinism and Lamarckism, Old and New," and in 1902 "The Lesson of Evolution."

After an absence of nearly forty years he paid a visit to this country, and received a hearty welcome from his many scientific friends. He was returning to his home at Christchurch when the announcement of his death on October 27 was received by telegram from the Cape. We are indebted to an obituary in the *Times* for some of the above particulars.

H. B. W.

NOTES.

THE Royal Society has this year made the following awards of medals. The awards of the Royal medals have received the King's approval:—The Copley medal to Prof. D. I. Mendeléeff, of St. Petersburg, for his contributions to chemical and physical science; a Royal medal to Prof. J. H. Poynting, F.R.S., for his researches in physical science, especially in connection with the constant of gravitation and the theories of electrodynamics and radiation; a Royal medal to Prof. C. S. Sherrington, F.R.S., for his researches on the central nervous system, especially in relation to reflex action; the Davy medal to Prof. A. Ladenburg, of Breslau, for his researches in organic chemistry, especially in connection with the synthesis of natural alkaloids; the Hughes medal to Prof. A. Righi, of Bologna, on the ground of his experimental researches in electrical science.

THE following is a list of those who have been recommended by the president and council of the Royal Society for election into the council for the year 1906, at the anniversary meeting on November 30:—*President*, Lord Rayleigh, O.M.; *treasurer*, Mr. A. B. Kempe; *secretaries*, Prof. Joseph Larmor and Sir Archibald Geikie; *foreign secretary*, Mr. Francis Darwin; *other members of the council*, Dr. Shelford Bidwell, Sir T. Lauder Brunton, Prof. J. Norman Collie, Prof. W. R. Dunstan, Prof. J. B. Farmer, Prof. F. Gotch, Dr. S. F. Harmer, Sir William Huggins, K.C.B., O.M., Prof. E. Ray Lankester, Dr. J. E. Marr, Mr. G. B. Mathews, Mr. H. F. Newall, Sir W. D. Niven, K.C.B., Prof. John Perry, Prof. E. H. Starling, Prof. W. A. Tilden.

AT a meeting of the council of the British Association on November 3 it was decided that, in consequence of strong representations by the local committee, the meeting at York next year shall be opened on Wednesday, August 1, which is earlier than the usual date of the opening meeting.

THE council of the British Association has received a gift of 50*l*. from Mrs. John Hopkinson, to be devoted to some investigation which may be suggested at the next meeting by the committee of recommendations.

THE Paris Academy of Moral and Political Sciences has awarded a prize of the value of 600*l*. to Dr. Calmette, of Lille, in recognition of his work in bacteriology and preventive medicine.

WE regret to see the announcement of the death, at forty-five years of age, of Prof. Walter F. Wislicenus, professor of astronomy in the University of Strasburg and editor of the "Astronomischer Jahresbericht."

A CHRISTMAS course of lectures, adapted to a juvenile auditory, will be delivered at the Royal Institution by Prof. H. H. Turner, F.R.S., on astronomy, from December 28 of this year to January 9, 1906.

DR. MAURITS SNELLIN informs us that he has resigned the directorship of the section of terrestrial magnetism and seismology at the Koninklijk Nederlandsch Meteorologisch Instituut. Dr. Snellin's private address is now Apeldoorn, Holland, and any papers intended for him personally should be sent to this address.

AT the inaugural meeting of the eighty-seventh session of the Institution of Civil Engineers, held on Tuesday, November 7, Sir Guilford Molesworth, K.C.I.E., the retiring president, formally introduced to the members his successor in the chair, Sir Alexander Binnie, who delivered an address to the members, in which he traced the influence of scientific thought and investigation upon the development of engineering practice. The president subsequently presented the medals and premiums awarded by the council for papers dealt with at the institution in the course of the past session.

THE fifteenth International Congress of Americanists will be held at Quebec on September 10–15, 1906. Papers in each division of the congress will take precedence in the order of the receipt of abstracts. Copies of regulations referring to papers may be obtained from Prof. F. Boas, department of anthropology, Columbia University, New York. The names of intending members or associates should be sent to Dr. N. E. Dionne, Librarian to the Legislative Assembly, Quebec.

Science reports that the Alvarenga prize for 1905 has been awarded to Dr. Chalmers Watson, of Edinburgh, for his essay entitled "The Importance of Diet; an Experimental Study from a New Standpoint." This prize is given by the College of Physicians of Philadelphia, and consists, each year, of the income of the bequest of the late Señor Alvarenga, amounting to about 36*l*. The next award will be made July 14, 1906, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition must be received by the secretary of the college on or before May 1, 1906.

WE regret to learn that Mr. William Henry Greenwood, the eminent metallurgist, died on October 31 at fifty-nine years of age. He was educated at the Royal School of Mines, and at various periods in his career he held important positions at the works of Sir J. Whitworth and Co., the St. Petersburg Ordnance Works, and the Birmingham Small Arms Works. From 1885 to 1889 he was professor of metallurgy at Sheffield. He was the author of a well known manual of metallurgy, of a treatise on steel and iron, and of a series of metallurgical lecture diagrams, and contributed various papers to the Institution of Civil Engineers, the Iron and Steel Institute, and other technical societies of which he was a member.

THE Society of Arts will commence its 152nd session on November 15 with an opening address from the chairman of its council, Sir Owen Roberts. Among the papers set down for the Wednesday evenings before Christmas is one on the commerce and industries of Japan, by Mr. W. F. Mitchell, at which the Japanese Minister will preside. Sir William Preece will give an account of the recent meeting of the British Association in South Africa, and Mr. F. Martin-Duncan will describe recent applications of the kinematograph for scientific purposes. A course of Cantor lectures by Prof. J. A. Fleming on electric waves will also be given before Christmas. Among the courses of lectures announced for the meetings after Christmas is one under the Cantor trust on modern warships, by Sir William E. White, and one under the Howard trust, by Prof. Silvanus P. Thompson, on high-speed electric generators. The usual course of juvenile lectures will be given this year by Prof. Herbert Jackson, the subject being flame and combustion.

BARON ERLAND NORDENSKJOLD has published through Reuter's Agency some details of his eighteen months' expedition to the Andes, which was undertaken for the purpose of penetrating the northern forests of Bolivia and studying the Indian tribes along the various tributaries of the Amazon in practically unknown districts. Baron Nordenskjold left England in January, 1904, his intention being to travel *viâ* the Peruvian port of Mollendo to Puno on Lake Titicaca, at an altitude of 12,000 feet, and thence to La Paz, the Bolivian capital. He visited in all three tribes, the Yamiacas, Guarayos, and Atsapuacas, who, until a couple of years ago, lived like people of the Stone Age. The two last mentioned, in the main, still retained their original customs. No white man had ever previously visited the Atsapuacas, but yet they were in possession of tools, which they had obtained through other tribes. The expedition was unable to get into contact with a fourth tribe. The explorers marched through their territory and were constantly watched by the people, who, while abstaining from molesting the strangers, would not have any dealings with them. Baron Nordenskjöld states that the Quichuas and Aymaras, living round Lake Titicaca and in the fells of the Andes, are an interesting study for the ethnologist, as they have retained many customs unaltered, or but slightly modified, since the time of the Incas.

FROM a report in the *Times* we learn that the old students of the Royal School of Mines resident in South Africa held their annual dinner at the Rand Club, Johannesburg, on October 7. Mr. J. Harry Johns presided, supported by Mr. A. R. Sawyer and Mr. H. H. Webb. In proposing the toast of "The Royal School of Mines," the chairman emphasised the importance of teaching students to put scientific knowledge to practical use. He laid stress upon the importance of training in mechanical engineering and electricity, and congratulated the Government upon choosing a thoroughly practical engineer to fill the chair of mining at the Royal School of Mines. Mr. Brodigan, in replying, endorsed the general opinion that, considering the national importance of the mining industry to Great Britain, the Government should endow more liberally the leading mining school of the world. A letter was read from the Commissioner of Mines (Mr. H. Weldon), in which he offered a scholarship of 32*l*. to be competed for by the mining students of the Transvaal Technical Institute. Mr. Webb proposed that a register should be kept of all old School of Mines students residing in the country, and stated that the Consolidated Gold Fields of South Africa would always be ready to provide work for a certain number of students who had finished the graduation course at the Royal School of Mines. The students would earn enough at such work to maintain them while they were gaining practical experience. In connection therewith, those who have studied at the Royal School of Mines are requested, should they come to South Africa, to send their names and qualifications to Mr. C. B. Horwood, Rand Club, Johannesburg.

THE tercentenary of the birthday of Sir Thomas Browne, author of the "Religio Medici," "Urn Burial," &c., physician and philosopher, who was born in Norwich on October 19, 1605, was celebrated in Norwich on October 19 with a remarkable display of enthusiasm and interest. A statue by Mr. Henry Pegram, A.R.A., has been placed in the Haymarket at Norwich, close to the site of Sir Thomas Browne's house, and was unveiled by Lord Avebury in the presence of a distinguished company, including representatives of the Royal Colleges of Physicians and Surgeons, London, and of several of the universities and learned societies, who were afterwards entertained at luncheon by the members of the memorial executive committee.

IN the *University Review* for October (ii., No. 6) Viscount Mountmorres writes on the development of the tropics. The article is an indictment of our colonial policy on the west coast of Africa, and the energy of other nations in developing their possessions in this region is contrasted with the lethargy exhibited in our treatment of our own colonies. This applies not only in commerce but in scientific investigations, and, save for several excellent

experimental botanical gardens, there is a whole class of important questions dealing with the mineral, vegetable, and animal products of the country which is practically left to private individuals for solution.

SIR FREDERICK TREVES gave the opening address of the winter series of the Edinburgh Philosophical Institution on October 31, Lord Rosebery presiding. Sir Frederick's subject was "disease"; he said that the common conception of disease is that it is a calamity, and its end destruction, whereas disease is one of the good gifts, for its motive is always benevolent and protective. He demonstrated his proposition by a number of instances, showing that the phenomena of disease always tend to recovery and repair, though he acknowledged that in the case of malignant disease the assertion could be made that there was nothing good in it, to which no answer could at present be given.

MR. L. W. LAMBE, of the Geological Survey of Canada, has favoured us with a copy of a paper, from the *Transactions of the Royal Society of Canada*, on species of Hyracodon and the ancestral horse-like genus Mesohippus from the Oligocene of the Cypress Hills, Assiniboia.

No. 3 of the Brooklyn, N.Y., *Museum News* records improvements and additions to the central and children's museums in that city. A special feature is the collection of insects in the children's museum, this group being regarded as a peculiarly suitable one for infantile study owing to the number of its representatives and their adaptations to different modes of life.

PART v. of the first volume of the *Records of the Albany Museum* contains papers on Hymenoptera by Messrs. Cameron and O'Neil, and two on fossil reptiles and fishes by Dr. R. Broom. Several new generic types of fossil reptiles are described, but their affinities are for the most part doubtful; the one fossil fish recorded is referred to the European ganoid genus Cœlacanthus.

AN elaborate account of the alimentary tract of the mosquito is contributed by Mr. M. T. Thompson to the *Proceedings of the Boston (U.S.A.) Society of Natural History*, vol. xxxii., No. 6. The ordinary gnat (*Culex pipiens*) and two other species of the same genus afforded material for the investigation, Anopheles not being sufficiently abundant.

THE contents of *Biologisches Centralblatt* of October 15 include an article by Mr. H. Kranichfeld on the probability of the preservation and continuity of favourable variations in animals, with arithmetical calculations; a second (to be continued), by Mr. K. C. Schneider, on the elements of comparative animal physiology; and a third (likewise not completed) on "neurons," or nerve-fibrillæ, by Dr. Max Wolff, of Jena.

IN the October issue of the *American Naturalist* Prof. B. M. Davis continues his detailed account of the structure of the vegetable cell, while Prof. T. D. A. Cockerell furnishes a diagnosis of the bees of the genus Diadasia, and Dr. H. W. Shimer describes a variety of the brachiopod *Terebratalia transversa* from Alaska, remarkable for the extreme thickness and rugosity of the shell, its abraded umbo, and the presence of a small perforation on each side of the aperture for the pedicel.

THE latest issues of the *Proceedings of the U.S. Nat. Museum* include a list of American cochlidian moths, with descriptions of new genera and species, by Mr. H. G. Dyar; and descriptions of new South American moths, by Mr. W. Schaus, of Twickenham. The latter comprises no less than 479 species regarded as new, many of them indicating previously unknown generic types, one of the latter being designated Rothschildia, in honour of the owner of the Tring Museum.

THE October issue of the *Zoologist* contains a summary of the results of last season's sealing in Newfoundland waters by Mr. T. Southwell, of Norwich. It is very interesting to note that, owing to a postponement of the date for taking the young, the product of a given number of seals has exceeded that yielded by the same number last year by no less than 779 tons. That seals are still abundant is evident from the statement that one of the vessels came upon a "patch" of some 600,000, of which only a few could be killed. These northern harp-seals are stated to differ from those killed further south.

To vol. xxvi., No. 3, of *Notes from the Leyden Museum* Dr. Jentink contributes an important and well illustrated paper on the wild swine of the Malay Archipelago. In the author's opinion all these pigs are indigenous, and each island form represents a distinct species, the long-snouted *Sus oi* of Sumatra thus being distinct from the Bornean *Sus barbatus*. Dr. Jentink appears to be unaware that Mr. Lydekker, on the evidence of photographs sent by Dr. H. N. Ridley, recorded in the *Field* for last year the existence of a representative of this long-snouted group in the Malay Peninsula.

MR. J. WIMMER, of Vienna, has sent us a copy of a "booklet" of sixty-four pages by himself entitled "Mechanik der Entwicklung der tierrischen Lebewesen," published at Leipzig by Mr. J. A. Barth. In this work the author discusses, with the aid of diagrams and mathematical formulas, the mechanical adaptations of animals of all classes to the conditions of their existence, and in relation to their modes of progression. One chapter is devoted, for instance, to the mechanics of the external form of the body, a second to those of its internal structure, and a third to those of the movements of the limbs. The work appears to be a concise summary of all the essential facts connected with the subject.

NATURE-STUDY on the part of children formed an essential feature in a paper on local museums (and the discussion which followed) read at the Worcester conference of the Museums Association, as reported in the October issue of the *Museums Journal*. While it was generally agreed that the proper function of local museums is to exhibit local faunas, floras, and antiquities, some difference of opinion was expressed as to whether it is desirable to enlist the services of children in making such collections, one speaker strongly disapproving of any encouragement being given to children to collect. The discussion also took into consideration the question as to whether museum curators should be called upon to assist in teaching, but the general opinion was that if any such instruction was demanded from them it should be confined to educating the teachers.

IN part xii. of the report of the Danish Biological Station to the Board of Agriculture, Dr. C. G. J. Petersen discusses the question whether plaice undergo their whole development, from egg to adult, in the open parts of the Baltic Sea. It is well known that the pelagic eggs of the plaice are shed between November and April (most of them in the depth of the winter), and also that the fry are pelagic until such time as they become unsymmetrical, when they seek the warm shallow water of flat sunny shores, this taking place in that part of the Baltic known as the Skaw during May and June. It has been found,

however, that the number of fry which visit the shores bears no proportion to the vast quantities of spawn that are shed; and it is concluded that this loss is accounted for by the fact that the whole development can only take place in cases where the young fish, when they cease to be pelagic, are in such localities that they can be carried by the current to the warm shallow water of the shores, such fry as sink in the cold depths of the Baltic itself inevitably perishing.

In the report on the botanic station, Grenada, it is mentioned that Mr. R. D. Anstead has been appointed agricultural superintendent, and Mr. G. F. Branch agricultural inspector.

New species of flowering plants recorded by Mr. J. N. Rose in vol. xxix. of the *Proceedings of the United States National Museum* include *Dahlia Chisholmi, Parnassia mexicana*—the first species of the genus from Mexico—a Heuchera and Polianthus, all from Mexico, and an umbellifer, from the coast of Georgia, with fruits like a Carum and leaves modified into hollow-jointed phyllodes, which is made the type of a new genus, Harperia.

A comprehensive account of the distribution and ecology of the flora of west Prussia, by Mr. J. B. Scholz, appears in vol. xi., part iii., of the *Schriften der naturforschender Gesellschaft* in Danzig. The original flora is described as Baltic, and this has been enriched by the invasion of a south-east European or pontic element, consisting of plants requiring warmth and dryness, that have advanced from the steppe regions. Characteristic pontic species are *Artemisia scoparia* and *Scutellaria hastifolia* in the river valleys, and in the region of the Vistula are found *Stipa pennata, Stipa capillata, Adonis vernalis, Campanula sibirica*, and others. The writer has paid special attention to the plant associations of the moors, heaths, and forests, as they help to elucidate former migrations of plants.

The analysis of the species of Hevea is complicated partly owing to the close relationship existing between them and partly on account of the difficulty of obtaining flowers and fruit. Dr. J. Huber, of the museum at Pará, who has made a study of Brazilian rubber plants, has published a synopsis in vol. iv. of the *Boletim do Museu Goeldi*, Pará. The section Euhevea has not been augmented, but in the section Bisiphonia the variety *cuneata* has been raised to specific rank, and two new species have been formulated. Of the twenty-one species enumerated, none seems likely to rival the well known *Hevea brasiliensis*; *Hevea Benthamiana* and *Hevea discolor* are considered to be the best rubber-bearing trees growing on the Rio Negro.

The *Century Magazine* for November contains an account of the very important Egyptian finds of Mr. Theodore M. Davis, of Newport, early in the current year. Among the tombs of the kings at Thebes were found those of Ioua and Tioua, father and mother of Queen Tii, wife of Amenhotep III. and mother of the heretic King Akhenaten. In addition to the ordinary appurtenances of tombs, such as vases, the find includes stools, chairs, beds, and other furniture magnificently overlaid with gold. One of the objects found was a chariot, the pole of which was broken, as were many other things; Maspero explains this as a method of killing the object and making it available for the use of the dead, and his view would hardly be questioned by anthropologists, or, we may suppose, by Egyptologists. The writer of the article, however, Mr. Greene, appears to doubt this explanation, holding that the custom may have been practised in Peru, but that the Egyptians were on too high a level of culture for it to be thinkable that such savage ideas survived among them. This view will hardly commend itself to experts; in fact, savage survivals are conspicuous in Egypt. The article is excellently illustrated with one plate in colours and many photographs, both of the tomb and the objects found there, and of the difficult task of conveying them to a place of safety in Cairo through a land in which honesty is not one of the prevailing features.

Mr. A. A. Read gives in *Engineering* the results of a comparison of the principal methods for the determination of manganese in iron and steel. The volumetric results are slightly lower than those obtained by the gravimetric method, but they agree sufficiently closely for practical purposes. With ferromanganese the bismuthate method gives rather too low a result as compared with the ammonium acetate method, probably owing to a small quantity of the permanganate having been decomposed and filtered off with the excess of the sodium bismuthate.

The Home Office has just published the annual return of the quantity and value of various minerals raised in the United Kingdom in 1904. The total value of the mineral output was 97,477,639*l*. as compared with 101,808,404*l*. in 1903. The decrease is due to a fall in the average price of coal. The production of coal, 232,428,272 tons, was the highest hitherto recorded. The output of gold from Merionethshire rose from 5495 ounces in 1903 to 19,655 ounces in 1904, the value of the gold being 73,925*l*.

We have received from the author, Dr. H. Potonié, professor at the Berlin School of Mines, a copy of the third edition of his interesting work on the origin of coal (Berlin: Borntraeger Brothers, 1905, price 4*s*.). It is an admirably illustrated pamphlet of 53 pages prepared to elucidate the diorama of a Coal-measure landscape exhibited by the Erkelenz Boring Company at the Liége International Exhibition. It is written in French and German in parallel columns, the French translation having been made by Prof. Gaspar Schmitz, of Louvain. Prof. Potonié's views as to the origin of coal are well known from his previous publications. He now brings forward further evidence to show that, just as at the present time the deposits of humus were almost exclusively formed *in situ*, in previous geological times it was also the rule that such beds were formed at the place where the plants grew from which they were derived.

Dr. van Rijckevorsel has sent us a copy of an elaborate and valuable discussion entitled "Constantly Occurring Secondary Maxima and Minima in the Yearly Range of Meteorological Phenomena." Dr. van Rijckevorsel, who is an honorary assistant attached to the Meteorological Institute of the Netherlands, and has for many years been known as a conscientious and painstaking investigator in the domain of meteorology and terrestrial magnetism, has divided the present work into two parts. The first portion exhibits ordinary mean daily values and smoothed means for many stations, mostly in the northern hemisphere, for a large number of years, and for various elements, with curves of the normal annual range of temperature. The principal results of the investigation show (1) that the resultant curve of daily normal temperature in the northern hemisphere is a continuous zigzag of maxima and minima; the rise from the winter minimum to the summer maximum is not uniform, but occurs in

spells or periods which at times are so strongly pronounced that the mean temperature falls, instead of rising, for several days together, and these irregularities, generally speaking, occur everywhere at the same time. (2) That this phenomenon is apparently similarly exhibited over the whole globe. (3) That probably other elements than temperature, even those not generally reckoned as meteorological, exhibit the same peculiarity. (4) That it is not improbable that these occurrences are connected with the sun's activity. In the second portion of the work the author endeavours to show that there is great probability that the same phenomenon really occurs in the southern hemisphere, but the data available do not at present allow of positive conclusions. The magnitude of the work undertaken may be gauged from the fact that the observations of some 3636 years have been discussed. In this portion of the discussion Dr. van Rijckevorsel has departed from the usual method of treating the means of observations from any particular locality as a separate unit, but has thrown all the observations for any year together, irrespective of place or date, as he considers that this method gives better data for the object in view.

THE *Proceedings of the Mathematical Society of Edinburgh* for the session 1904–5 open with a systematic paper on the properties of the envelope of the Wallace or Simson line by M. Collignon, including not only geometrical, but also kinematical considerations. Dr. Mackay also publishes a bibliographical note intended to accompany Collignon's memoir. Mr. R. F. Muirhead gives new proofs of Newton's theorem on sums of powers of roots, and also of Waring's expression for the sum of the powers in terms of the coefficients. Mr. E. B. Ross contributes a neat discussion of the degree of contact between a curve and its envelope; and in a paper on polar loci Mr. D. G. Taylor, in order to get rid of the confusion due to multiple values of r for what seems to be graphically one value of θ, imagines an infinite number of parallel planes one above the other slit up from 0 to ∞ along the initial line and joined together so as to form a kind of helical surface. Dr. Muir communicates a note on the condensation of continuants, and Prof. Bromwich gives a useful method for distinguishing the ambiguous cases in the solution of spherical triangles.

IN the *Transactions of the Faraday Society* (vol. i., part iii.) Mr. Sherard Cowper-Coles gives an interesting account of the various processes which have been suggested for increasing the rate of deposition of electrolytic copper on a commercial scale. It is claimed that the centrifugal process is at least ten times as rapid as any other process. When the mandrel which constitutes the kathode is rotated with sufficient rapidity, smooth, thick deposits of copper in the form of tubes are obtained which show no trace of lamination. The paper is illustrated by numerous plates, in which the influence of the rate of rotation on the character of the electrolytic copper is clearly evident.

THE supposition that radium is a disintegration product of uranium has received considerable support from the investigations of Strutt, McCoy, and Boltwood. The question whether the production of radium from a pure uranium compound can be experimentally detected would, however, seem to be answered in the negative by recent experiments of Mr. Bertram B. Boltwood, published in the *American Journal of Science*, vol. xx., 1905. Observations on a solution containing 50 grams of uranium, which extended over a period of 390 days, indicate that the quantity of radium formed is less than $1{\cdot}7\times10^{-11}$ gram. This is less than one sixteen-hundredth of the quantity which would be expected from the disintegration theory, and the author concludes that one or more products of a slow rate of change intervene between uranium and radium.

THE *Revue générale des Sciences* for September 15 contains a reprint of a lecture which was delivered by Prof. P. A. Guye before the Chemical Society of Paris on new researches on the atomic weight of nitrogen. The author reviews the results already obtained, and concludes that sufficient differences exist to render fresh determinations necessary. The classic gravimetric methods are not considered sufficiently accurate, and a description is given of new methods of determining the atomic weight of the element based on the analysis of nitrous oxide. A spiral of iron wire is heated electrically in a known weight of the gas and the increase in weight found. In another series of experiments, an iron spiral is similarly heated in a known volume of nitrous oxide. The mean value assigned for the atomic weight is 14·009. An article is also contributed to the same number by MM. J. de Kowalski and J. Dalemont on the teaching of applied science at Fribourg University.

AN important paper by Mr. H. v. Steinwehr on the influence of the size of crystals of mercurous sulphate on its relations to electromotive force ("Vorlaüfige Mitteilung über den Einfluss der Korngrösse auf das electromotorische Verhalten des Merkurosulfats") has lately been published in the *Zeitschrift fur Instrumentenkunde*, 1905, Heft. vii. The paper deals with a subject of great interest, and one which at the present time is occupying a great deal of attention in all countries in connection with the preparation of standard cells. The author experimented on samples of mercurous sulphate obtained from different makers, and found that they gave a difference of electromotive force equal to 5×10^{-4} volts; it was also found that they varied in solubility. On examining them under a microscope a difference in the size of crystals was observed, the smaller crystals having a higher solubility and higher E.M.F. The subject was pursued both in the direction of reducing the crystals by grinding and of increasing them by crystallisation, and the same result was obtained, viz. the larger the crystals the lower the solubility and the smaller the E.M.F. The author thinks it highly probable that the size of crystals is the chief, if not the only, cause of the differences observed in different samples of mercurous sulphate. He further criticises the conclusions of Hulett that it is the presence of basic salt that affects the result. In conclusion, he discusses the electrolytic method of preparation suggested by Hulett and Fr. A. Wolff and recommended by Carhart for standard cells, stating that it is bound to lead to the production of crystals of very varying size, and the device used by them of continuing the stirring after the circuit is broken cannot have the desired effect, as the crystallisation of mercurous sulphate is very slow. We await with interest the further communication by the author, and hope he will then have some suggestion as to an improved method of preparation.

WE have received part i. of a book on leather dressing, including dyeing, staining, and finishing, by Mr. M. C. Lamb, director of the leather dyeing department, Herold's Institute, Bermondsey. This portion, containing thirty pages, is the first of twelve monthly parts of which the book will consist; it deals with sorting, splitting and shaving, and is well printed and illustrated, the working parts of the machines described being explained by

diagrams. Until the book is completed it would be impossible to form an opinion of its value, but the first part promises well.

THE annual report of the board of regents of the Smithsonian Institution for the year ending June 30, 1904, has now been published. As usual, the general appendix to the report, which makes up about seven-eighths of the volume of 804 pages, will prove most interesting to British readers. This appendix contains more than fifty articles upon scientific subjects to which special attention was directed during the year with which the report deals. Five of the articles represent addresses at the congress of arts and sciences held at St. Louis during September, 1904. Among these may be noticed that of Prof. H. H. Turner, F.R.S., on some reflections suggested by the application of photography to astronomical research; Mr. C. T. R. Wilson, F.R.S., on condensation nuclei; and Sir William Ramsay, K.C.B., F.R.S., on the present problems of inorganic chemistry. Two addresses delivered at the Cambridge meeting of the British Association are also reprinted. A generous selection of articles from important American, French, German, and British scientific publications is included, and nearly every department of scientific knowledge is represented. There are several articles which appear to have been contributed specially to this report, and of these may be mentioned the essays of Dr. S. P. Langley on experiments with the Langley aerodrome (see p. 645), Dr. J. O. Skinner on the house sparrow, Dr. Theodore Gill on flying fish and their habits, Mr. Edgar L. Hewett on a general view of the archæology of the Pueblo region, Dr. Ales Hrdlička on the painting of human bones among the American aborigines, and Mr. W. C. Gorgas on the sanitation of the Isthmian Canal zone. The profusion and excellence of the plates and other illustrations again call for remark. Readers who are fortunate enough to have access to these yearly reports are provided with an excellent means of keeping abreast of current scientific studies.

OUR ASTRONOMICAL COLUMN.

ITALIAN OBSERVATIONS OF THE RECENT SOLAR ECLIPSE.—A series of valuable observations of the partial eclipse of the sun was made at Aosta (Italy) on August 30, and the results are given in No. 17 (1905) of the *Comptes rendus*.

The times of contacts, the meteorological changes, and the spectroscopic phenomena were observed in an atmosphere of exceptional purity, and, in connection with the last named, Dom Cl. Rnzet describes what he believes to be a unique observation. At about 1h. 40m. (Paris M.T.) the cusp of the crescent sun (position angle about 90°) was projected on to the widened slit of the spectroscope, arranged perpendicular to the solar limb, and the lines C and D_3 were seen very bright and showing a hazy, cloud-like prominence.

The bright line in each case, however, was divided sharply into three parts. First, on the red side was a broad bright line with sharp edges, then came a narrow, well defined *dark* line, and finally, on the more refrangible edge, a bright line showing the form of the prominence was seen.

MARTIAN METEOROLOGY. In No. 8, vol. liii., of the *Harvard College Observatory Annals*, Prof. W. H. Pickering discusses a number of photographs of Mars some of which were taken with the 13-inch Boyden telescope at Cambridge (Mass.) in 1888, and the others at Mt. Wilson, with the same instrument, in 1890. Although these photographs do not show the canals and lakes, they show sufficient variation, due to meteorological changes, for a discussion of Martian meteorology.

Prof. Pickering describes, in order, the appearance and disappearance of clouds, snow, &c., and deduces therefrom some valuable suggestions as to the seasonal changes which take place on or above the planet's surface, giving, in each case, the equivalent terrestrial date at which these changes occur. Nine reproductions from the original photographs, on a scale of 1 mm. = 200 km., accompany the paper, and show the clouds, &c., to which Prof. Pickering refers; the Sinus Sabæus and the Syrtis Major are also shown on some of them. On two occasions the height of the clouds above the Martian surface was measured, giving about 15 miles as the result, and Prof. Pickering suggests that the existence or non-existence of such clouds in the equatorial regions may account for the discrepancies noted between various estimations of the amount of the polar flattening.

In conclusion, Prof. Pickering points out that there is now direct evidence of an effective atmospheric circulation of moisture on Mars which would seem to account, adequately, for the observed transfer of precipitation, during the Martian year, alternately from pole to pole.

A 300-YEAR CYCLE IN SOLAR PHENOMENA.—From a lengthy discussion which appears in No. 1, vol. xxii., of the *Astrophysical Journal*, Mr. H. W. Clough, of the Washington Weather Bureau, arrives at the conclusion that a 300-year cycle exists in solar, and the allied terrestrial, phenomena. In the first place, Mr. Clough discusses the observations of numerous terrestrial phenomena which are supposed to be dependently associated with solar changes, and finds that a 36-year cycle is common to these and to solar variations. He then shows that the 36-year cycle varies in length during a cycle of 300 years, and supports this by reference to old observations of various terrestrial phenomena, *e.g.* auroræ, time of grape harvest, &c., extending back to the early centuries of the Christian era.

SOME SUGGESTIONS ON THE NEBULAR HYPOTHESIS.—In a paper communicated to the Royal Society of Edinburgh, and published in part vii., vol. xxv., of the *Proceedings* of the society, Dr. Halm makes some suggestions, concerning the probable genesis of the solar system, which may overcome some of the difficulties experienced in the acceptance of Laplace's theory. Whilst the Laplacean hypothesis considers that the matter now forming the planets was thrown off by the original *rotating* nebulous mass, a consideration which is not consistent with the principle of the constancy of the rotary momentum in a system, Dr. Halm suggests that the conditions necessary for the formation of planets were not introduced until after the solar body had condensed from a *non*-rotating nebula into a spherical body having a diameter probably less than the distance of Mercury. This spherical body then encountered a swarm of meteorites, and finally a ring of these bodies, rotating with orbital velocities about the solar nucleus, was formed.

The planets were formed subsequently by the evacuation of the ring by the larger nuclei existing therein, their rotary motions being generated by the tangential impulses given to each nucleus by the smaller masses falling into it. Many subsidiary considerations are discussed in Dr. Halm's paper, but they are too lengthy to be given here.

SYSTEMATIC ERROR IN TRANSIT OBSERVATIONS OF JOVIAN SPOTS.—We recently referred in these columns (September 21) to a suggestion made by the Rev. T. E. R. Phillips to account for a systematic error in eye-estimates of the transits of Jupiter's spots, and, in the current number of the *Observatory*, Mr. Stanley Williams supplements Mr. Phillips's remarks with a brief discussion of his own results, in which a similar, but larger, systematic error seems to exist. Mr. Williams suggests that the phase-darkening of any long feature such as the red spot, or hollow, may introduce the error. For example, at the quadrature preceding opposition the planet's disc for some distance from the preceding limb is less bright than it is near to the following limb, but at the quadrature following opposition the reverse is the case. As the spot and the hollow are so long, the transit is observed, in practice, by comparing the relative spaces between their ends and the limb, and if the latter are unequally bright, irradiation may lead to such a systematic error as the one which appears in the results.

THE ORBIT OF σ CORONÆ BOREALIS.—As the orbits calculated from the observations of σ Coronæ Borealis show great divergence, ranging from 200 to 800 years, Prof. Doberck has investigated this subject, and now publishes the results in No. 4051 of the *Astronomische Nachrichten.* The set of elements which he gives depends upon Herschel's measures of the angle, and shows the period to be about 1679 years, and the motion to be direct.

Prof. Doberck states that the hypothetical parallax of this system is 0″·064, but the actual parallax is probably smaller, and that the mass of the system is probably greater than that of the sun.

RADIAL VELOCITIES OF CERTAIN VARIABLE STARS.—The results obtained by Prof. Frost from a series of spectrographic observations of certain variable stars (chiefly of the Algol type) are given in No. 3, vol. xxii., of the *Astrophysical Journal.*

R Canis Majoris, Z Herculis, and U Sagittæ are shown with certainty to be spectroscopic binaries, their determined velocities corresponding, in sense, to what would be expected from the phase in the light variation at the time of observation.

VARIABILITY OF THE ASTEROID (444) GYPTIS.—The variability of the apparent brightness of the minor planet (444) Gyptis is suggested by the results obtained from a series of observations made at Heidelberg and published by Dr. W. Valentiner in No. 4050 of the *Astronomische Nachrichten.*

In the same journal it is suggested, by Dr. Palisa, that the magnitude of minor planet 1905 RB is also variable.

CONFERENCE OF DELEGATES OF LOCAL SCIENTIFIC SOCIETIES.

AS it was not deemed expedient to call a meeting of the delegates of the corresponding societies of the British Association during the session in South Africa, it was arranged that a special conference should be convened subsequently in London. This meeting was held at the rooms of the Linnean Society on Monday and Tuesday (October 30 and 31), and was largely attended by representatives of various scientific societies in England, Scotland, and Ireland.

Dr. A. Smith Woodward, who presided at the conference, delivered an inaugural address rich in sympathy with the efforts of the provincial societies to further the progress of science, yet not without a word of gentle reproof to such societies as give undue prominence to the picnic element, which rather tends to the estrangement of the working naturalist. Probably the best work of the smaller societies was, in the chairman's opinion, that of instruction in the current progress of science. He suggested that it would be salutary to dwell on the unsolved problems of science, and pointed out the need of books which should treat of our ignorance rather than our knowledge, and so indicate the direction in which investigation is still urgently needed. Dr. Woodward condemned as extremely unfair the growing practice of certain societies to solicit men of scientific renown to deliver popular lectures without fee. Warm approval was expressed of the recent action of the British Association in seeking to extend its usefulness by including within its union the smaller non-publishing societies and field clubs, which will form henceforth a new class of *associated* societies distinct from the group of *affiliated* societies which publish original investigations in science.

Dr. W. Martin, of the Temple, introduced a discussion on the law of treasure trove, with the view of inducing the various local societies to assist in the preservation of antiquities found within their sphere of influence. While generally defending the law he advocated some revision, especially in the mode of its administration. He suggested that notices should be widely circulated, say at the post-offices throughout the country, explaining to the public that the finder of valuable relics would receive reasonable remuneration. In a similar way, relics like stone implements might be secured, where desirable, by the State.

Mr. Morris Colles, the director of the Authors' Syndicate, and Mr. Harold Hardy explained the present law of copyright as it affects the published proceedings of scientific societies. The general sentiment of the meeting seemed, however, to be in favour, not of hindering in any way the re-publication of papers, but rather of encouraging the dissemination of knowledge by favouring publication, naturally with due acknowledgment of the original source of information.

Prof. G. S. Boulger read an interesting paper on the preservation of our native plants, which led to a valuable discussion. There seems no doubt that some of the rarer indigenous plants are in serious danger of extermination, not wholly through thoughtlessness on the part of the public, but partly through the cupidity of botanists—an evil which has increased since the extension of nature-study. It was proposed that legislation should ultimately be sought for the protection of certain plants, but that meanwhile a circular should be issued bringing the subject before teachers, members of field clubs, and others interested in our flora and likely to assist in its conservation.

In addition to attending the two meetings, the delegates visited the Museum of the Royal College of Surgeons under Prof. Stewart, and, on the evening of October 30, dined at the Royal Societies Club, where they were received as guests.

ZOOLOGY AT THE BRITISH ASSOCIATION.

THE work of Section D was formally opened on Wednesday, August 16, with the president's address on "The Distribution of African Fresh-water Fishes," which has already been printed in NATURE (August 24, p. 413). This was followed by a paper by Mr. L. Doncaster entitled "Recent Work on Gametogenesis and its bearing on Theories of Heredity," which took the form of a *résumé* of the most important recent work on the relation between the phenomena of nuclear division and those of heredity. It was shown that whilst ample confirmation had been obtained of Weismann's hypothesis that the chromosomes are the bearers of inherited characters, yet the most recent work on the maturation of the germ cells had demonstrated the fact that they contained a mechanism which seemed precisely adapted to bring about that segregation of characters which forms the most fundamental part of the Mendelian theory; it was difficult, therefore, to believe that the two things were unconnected. The remainder of the paper was devoted to the consideration of certain obvious difficulties standing in the way of a complete correlation.

The programme for Thursday, August 17, was opened by Dr. J. D. F. Gilchrist with a paper on cases of extensive mortality among marine animals on the South African coast, with suggestions as to their cause or causes. After narrating specific cases of enormous quantities of fish either dead, or alive but "in a stiffened condition," being thrown up on various points of the coast, the author suggested that these occurrences might be due to a peculiar feature of the Cape seas, viz. the great difference in temperature, salinity, and contents of the warm Agulhas Stream of the Antarctic drift current, and expressed the hope that his notes might be of some use in directing attention to this problem and securing additional evidence in connection therewith. The paper was followed by a demonstration of the more interesting forms in a collection of deep-sea animals shown in the museum of the South African College, special attention being devoted to certain questions, such as methods of reproduction of deep-sea fish, the significance of luminous organs, and parasitism. A short paper by Mr. A. H. Evans on the ostrich and its allies was intended to be introductory to a contribution on ostrich-farming by the Hon. Arthur Douglass, one of the pioneers of the industry in the colony. In the latter paper the writer supplied a large amount of interesting information relating to the first commencement of ostrich farming in 1867 and its growth up to the present time, the best climatic and general conditions for the industry, the results of artificial hatching as used in the early days of the industry as compared with present methods of rearing the chicks, the principal diseases of the birds, the present different methods of farming them, the growth of the export of feathers and the range of values, the improvement of the breeds by selection to obtain better feathers,

the prospects of future development of the industry in South Africa, and of its being successfully developed in other countries. The reports of the committees on grants, which were also taken on this day, did not offer any special points of general interest.

The greater part of the sitting on August 18 was devoted to a paper on the origin of mammals, by Prof. Broom, in which the author had occasion to make extended reference to his work on the Triassic reptiles of South Africa in support of his views of a reptilian origin for the mammalian group. The author gave reasons for believing that in early Permian times a cotylosaurian reptile, owing to its frequenting marshy ground, took to walking with its body well supported off the ground. This habit gave rise to the forward direction of the ilium, and to the pubis and ischium being turned backwards, as also to the great development of the precoracoid. No member of this first stage in the mammalian line was at present known, but Pareiasaurus was apparently a considerably modified offshoot from it.

The next stage in the development arose by the marsh animals finding that the new modification of the limbs was specially suitable for progression on land. The new type of land animal was better equipped than the normal reptile, and took to predatory habits and became an active carnivorous animal. These early carnivorous types form the order of Therocephalians, of which about twenty genera are known. Between the Upper Permian and the Upper Triassic times the Therocephalians gave rise to the much improved Theriodonts or Cynodonts. These Theriodonts are almost mammals in every detail of structure, the only essential difference being that the lower jaw has still a small articular element, which hinges on a small quadrate bone. The change from the Theriodont to the mammal was probably brought about by a slight change of habit necessitating some antero-posterior movement of the jaw, the small quadrate bone becoming first a plate of bone and then a plate of cartilage—the inter-articular cartilage, the dentary taking the place of the articular. Neither the auditory ossicles nor the tympanic have ever had anything to do with the articulation. The mammalian malleus was held to be the reptilian extra-stapedial and the mammalian incus the supra-stapedial. The connection between Meckel's cartilage and the malleus, which is hyomandibular, was held to be similar to that between the extra-stapedial and the mandibular cartilage in the crocodile. The mammalian tympanic was considered to be the homologue of the distinct tympanic bone of Anomodonts and Theriodonts. The paper gave rise to considerable discussion, in which Prof. W. B. Scott of Princeton, the president, and others took part, and was followed by a communication from Dr. W. F. Purcell on some early stages in the development of Peripatus, in which the writer maintained that an examination of the segmentation stages of the ovum of *Peripatus balfouri* preserved in formalin shows that the endodermal cells are oval or spherical bodies with well defined convex or flattened contours, but without any anastomosing branches connecting the cells with one another or with the ectoderm. The embryo in the segmentation stages is therefore not a syncytium, as maintained by Mr. A. Sedgwick. The remainder of the session was devoted to an important paper on the habits and peculiarities of South African ticks, by Mr. C. P. Lounsbury, which the sectional committee resolved to print *in extenso* in the *Proceedings* of the association, whilst certain details in the structure of the buccal apparatus of a tick (*Haemaphysalis punctata*) were elucidated in a concluding joint paper by Drs. Nuttall, Smedley, and Cooper.

The first day of the proceedings at Johannesburg (Tuesday, August 29) was opened by Prof. Herdman, F.R.S., who gave an account, illustrated with lantern views, of his well known investigations on the pearl-oyster beds of Ceylon. This was followed by an interesting communication on Cephalodiscus by Dr. S. F. Harmer, F.R.S., in which the author gave a preliminary account of the new species discovered in African seas by Dr. Gilchrist. The session was concluded with a demonstration of ankylostoma preparations by Mr. A. E. Shipley, F.R.S.

The programme for Wednesday, August 30, was opened by Prof. E. B. Poulton, F.R.S., who gave a lecture, illustrated with lantern slides, on mimicry in South African insects. This was followed by a paper by Mr. W. L. Sclater, director of the South African Museum, on the migration of birds in the southern hemisphere. For the purposes of the paper the author took the list of birds contained in the recently published volumes of the "Fauna of South Africa," written by the late Dr. Stark and himself, together with those of the fourth volume, shortly to be issued. The number of species described in the four volumes was 814, which the author divided into five categories, as follows:—residents, 631; northern migrants, 76; African migrants, 21; partial migrants, 50; and island breeders, 36. Mr. Sclater stated that he considered it would be most unwise to evolve any theories on migration in South Africa at present, owing to the dearth of observations hitherto recorded. He was, however, in hopes of making some advance by the distribution of schedules among the lighthouse keepers along the coast, teachers in the schools all over the country, and any others who would undertake to make the observations, for the purpose of recording, day by day and month by month, the appearance of different species of birds.

Mr. C. B. Simpson, the Transvaal Government entomologist, then read a paper on locust destruction in the Transvaal during the season 1904–5, in the course of which the writer gave an outline of the history of the locust pest in other countries, and then proceeded to describe the locust invasions in South Africa, due to two species, *Acridium purpuriferum* (the purple locust) and *Pachytylus sulcicollis* (the brown locust). Although both species were shown to have many natural enemies, yet every natural method of decimation was found to be insufficient. Therefore, in order to save the farmers' crops, recourse had to be had to artificial means. Amongst the methods adopted were beating by hand, tramping with stock, crushing with rollers, burning grass, driving into trenches, the use of locust screens, and spraying. The screens were described in detail with the help of the lantern, the author stating that twenty miles of them were distributed throughout the Transvaal for the use of farmers. Spraying was, however, the most efficient means for the destruction of locusts. The spray used was arsenate of soda, and it was given to the farmers free, while the screens and spray-pumps were lent without charge. The results of the campaign in the previous year had been most gratifying. It was of course stated that the Transvaal, still less South Africa, could not expect to eradicate the pest completely on account of the vast area of unoccupied country; but the author's department did hope to place in the hands of the farmers a means whereby by combined action they could kill the insects and protect their crops. If they could do this they would consider that success had been achieved. With the purple locust the author believed they had proved that the farmers could do this, but with the brown locust they had not yet had sufficient experience to be able to tell whether they could prevent injury or not. The concluding paper of the session, by Dr. H. Lyster Jameson, was entitled "On Some South African Land Planarians," and dealt with certain points in their anatomy.

The concluding meeting of the section was held on Friday, September 1, on which day Prof. W. B. Scott, in an opening paper on convergent evolution as illustrated by the Litopterna, maintained that while convergent evolution was admitted by most naturalists to be a frequent and important phenomenon, there was a great difference of opinion as to how nearly identical the results of such a mode of development might be. So far as the Litopterna were concerned, there were striking resemblances to certain Perissodactyls in teeth, skull, and skeleton, but the differences were many and fundamental. It did not appear at all likely that so complex a structure as a mammalian skeleton was ever produced in identical terms by two independent series.

In the course of the succeeding paper, on a neurosyncytial theory of development, Dr. W. H. Gaskell, F.R.S., referred to his theory of the origin of vertebrates, and pointed out that it was based upon the paramount importance of the central nervous system as the chief factor in the upward progress of the animal kingdom. Every line of investigation pointed to the conclusion that the

vertebrate arose from that group of invertebrates which possessed a central nervous system most nearly similar to that of a low vertebrate such as Ammocœtes, an invertebrate, therefore, belonging to the group of arthropods. This argument had been worked out by the author in a series of papers published in the *Journal of Anatomy and Physiology*, and receives especial support from the palæontological record. For the dominant race now, the biped mammal man, arose undoubtedly from the highest race evolved up to that time—the quadrupedal mammals; these in their turn originated from the dominant reptiles; these again from the amphibians, which were the most highly organised group of their day. The amphibians themselves came from the dominant race living in the sea at the time—the fishes; so, too, according to the author's theory, the fishes arose directly out of the race previously dominant, *i.e.* the arthropod group. This theory necessitates the formation of a new alimentary canal at the transition from the arthropod to the vertebrate—a requirement which is no more unlikely than the formation of a new respiratory apparatus at the transition of a fish into an amphibian. The reason why others have found this formation of a new alimentary canal so difficult of acceptance is because embryology—and embryology alone—in its recent teaching makes the alimentary canal, and not the central nervous system, the important organ around which the animal is built up. The author, basing himself especially on Braem's papers in the *Biologisches Centralblatt*, pointed out that in reality the germinal layer theory was a physiological and not a morphological conception, that the one criterion of hypoblast was not its mode of formation but its ultimate fate; whether or no, the definite alimentary canal was formed from it. Morphological laws of development must exist, but to quote Samassa, "one thing can be said with certainty at the present time, the germinal layer theory is not one of them." The author suggested a re-consideration of the whole matter, and, starting with the adult, pointed out that the tissues of the body fall naturally into two great groups, those which are connected with the central nervous system, the master tissues of the body, and those which live a free existence without any such connection. The body might be looked upon as composed of a neuro-epithelial syncytium, in the meshes of which free cells live.

Prof. Cleland, F.R.S., in conclusion, read a communication on the growing-point of the Vertebrata, in the course of which he pointed out that while the medullary folds appear in close connection with the blastopore, and the parts concerned with the cranium and its contents are the first to appear, both mesoblastic somites and spinal nerves appear in succession, each metamere behind that which is immediately proserial to it. It follows, therefore, that it is from the short space between the medullary folds and blastopore that new metameres of the neuro-muscular system are formed, and there is no reason to doubt, the author held, that the visceral system is extended in the same manner. The nucleated corpuscles of this region furnished, therefore, in his opinion, the parents of the corpuscles of which the successive metameres of the trunk are composed, and they do so by giving off successive series of corpuscles which belong each to a particular metamere.

EDUCATIONAL SCIENCE AT THE BRITISH ASSOCIATION.

THE most noteworthy feature in the educational science section at the South African meeting of the British Association was the address of its president, Sir Richard Jebb, an address which was originally delivered at Cape Town, and repeated with a little variation at Johannesburg. The address, which was printed in full in NATURE of September 28 (p. 545), dealt with the idea of a university and the distinction which marks off the teaching of a university from that of a higher technical school or similar institution.

The subject of the address was the more apposite in that the most pressing educational question in South Africa at the present time is the creation of a teaching university. The present Cape University is an examining body only, and it has been suggested that the time has come for it to grow into a teaching university by the combination of the colleges at present preparing for its examinations, much as the University of London was so recently re-created. The difficulties, however, both of funds and of conflicting interests have not yet been overcome.

At Johannesburg, also, the successful start of the recently established technical institute has led to a plan for its growth into a university, with engineering, agriculture, law and education as its main faculties, and it seems not unlikely that liberal financial support would be forthcoming should it be decided on fuller consideration to adopt such a scheme.

At the sectional meetings a large proportion of the papers was contributed by teachers resident in South Africa, so that opportunities were afforded to the visitors of learning what were the more pressing educational problems, and to the local members of discussing these problems on a wider platform. At Cape Town the Rev. W. E. C. Clarke gave a general review of the development of education in the colony, laying particular stress on the perennial difficulty of providing any efficient scheme for the instruction of the widely scattered country population. Mr. Clarke's paper excited considerable interest, and led to renewed discussion, especially the latter portion, which dealt with the status of the teacher in Cape Colony. He spoke of the power of the Cape Teachers' Union, and deplored the tendency of their conferences to be rather exclusively occupied with questions of salary and allowances instead of leading public opinion on matters of educational policy.

Mr. W. W. Way, principal of the Graaf Reinet College, also contributed a brilliantly written and hard-hitting paper on the disabilities of the South African schoolboy. He pointed out how the semi-tropical climate, the wealth of sun and air, the freedom and isolation of the life of the South African boy, while they produce an alert and self-reliant race, do not work well in the interests of education. The youth are essentially undisciplined and unintellectual, while the early physical development brings its own dangers. Mr. Way touched upon the further difficulties, both as to mind and morals, which arise out of the proximity of the native, the co-existence of two languages, the inferior type of teacher that characterised the past, and the narrowing influence of many of the religious bodies in the country. Nothing but an ampler endowment and a general rise in the status of the teacher can induce in the future South African a proper respect for his intellectual development.

The general history and administration of education in the other colonies were thoroughly dealt with at the Johannesburg meeting in a series of papers contributed by Mr. Warre Cornish, Mr. Gunn, and Mr. Duthie. They all showed certain common problems the scarcity of suitable teachers and the necessity of improving their status and training, the expense of providing adequate school buildings, and the difficulties induced by the isolation of the farms. This latter question of education upon the Veld was also dealt with in a breezy paper by Mr. J. H. Corbett, a vivid and sympathetic presentation of the case, in which the author evidently trusted more to the self-devotion of the individual teacher than to any possibilities of organisation.

The second meeting at Cape Town opened with a paper by Mr. W. M. Heller on the methods of teaching science, with an introduction by Prof. H. E. Armstrong. At its close Mr. Oscar Browning expressed his dissent from the current view of the "heuristic" method as an instrument of education it was valueless, and all good teachers of history and literature had worked by this method long before Prof. Armstrong resuscitated its unhappy name. Mr. A. D. Hall claimed that the value of the "heuristic" method lay in the inspiring ideal it set up; unrealisable as it might be, the natural tendency of the teacher was to drift along the other easier way of giving instruction *ex cathedra* instead of by the path of discovery and experiment. Mr. G. Fletcher, however, rather hit off the feeling of the meeting when he suggested that a close time should be declared for discussions of the "heuristic" method, which had in past years occupied far too much of the

attention of the educational section. Mr. Fletcher's own paper, which followed, dealt with the development of technical education in a new country, and suggested that many of the methods which had been successful in Ireland in the way of creating public interest and of eliciting the cooperation of the locality might well be adopted in South Africa. Nor should the Administration be deterred from making a start with technical education at any centre by reports as to the apathy of the residents; Irish experience would seem to show that a supply of good instruction would always produce an increasing demand for it.

The very important question of agricultural education was treated at Johannesburg by Mr. F. B. Smith, the Director of Agriculture in the Transvaal, and by Mr. A. D. Hall at Cape Town. Mr. Smith showed how efficiently an intelligence department had already been organised in the matter of agriculture in the Transvaal, where the farmer had at his call a service for investigation and advice which could not be rivalled in any other British country. An enormous amount of work had now been done on such matters as the introduction of improved crops, the eradication of stock diseases, &c., and the Afrikander farmer was beginning to rely upon the help of the department. Mr. Smith further outlined the nature of the course it was proposed eventually to establish in the Transvaal in connection with the future university. Mr. Hall was disposed to think that questions of economy would necessitate the colonies concentrating their efforts chiefly upon their expert staff for investigation and work among the current generation of farmers, and that there was not the same call for another staff to give instruction in the higher branches of agricultural science. The type of instruction for which the most pressing demand existed was a practical training in more improved methods of farming, and this could well be developed in connection with the experimental farms that had already been instituted in various parts of the country. It seemed as yet hardly worth while to create an elaborate teaching institution to produce the small number of experts and Government officers whom the country would require yearly, since suitable men could be picked out during the earlier practical courses of instruction and sent home to complete their scientific training.

One question, which recurred constantly during the tour, both in section meetings and in conversation, was that of native education, a thorny subject interwoven with many prejudices, both racial and religious. The general feeling among colonials is almost wholly opposed to education of what may not unfairly be called the ordinary missionary type, which seeks to teach the native to read and write English. Many large employers of labour refuse to engage any native acquainted with English, and other experienced men declare that the only effect of such a bookish training as has been given in the past is to make the native parasitic, either upon the white community or his more primitive fellows. But education by means of handicrafts, and proceeding entirely in the natives' own language, meets with general approval, both as supplying a much desiderated discipline and making the native more efficient economically, and also as likely to prove a sound method of eventually leading the native on to a higher plane of civilisation. This is essentially a matter on which the visitor can only speak with diffidence; indeed, it is claimed that many of the difficulties have arisen from the ill-considered, though well meaning, action of people at home.

The papers of more general interest included a discourse by Dr. J. H. Murray on "the world of words," in which he discussed, with appropriate illustrations from the English language, the various types of words and the manner in which they originated. Dr. Brill, rector of the Grey College at Bloemfontein, again submitted a paper of great interest on the origin of the "Tael," the form of Dutch commonly spoken throughout South Africa. The Tael he holds to be a pure Dutch, "clipped," however, by the removal of practically all inflexions, genders, and irregular forms. What little foreign element exists in the language he attributes to early intercourse with the East, and regards it in the main as of Malayo-Portuguese origin. The members of the British Association who were interested in education had many opportunities of seeing the schools in the centres they visited, and also of intercourse with the teachers at work in them. The raw material with which the latter have to deal may not as yet have imbibed any great keenness for learning, but the general attitude of the citizens of the country towards education, as indicated, for example, in such matters as school buildings (often in the smaller towns of Cape Colony the most notable public building was the school), shows a life and determination which will not be long before bearing fruit.

THE SCOTTISH NATIONAL ANTARCTIC EXPEDITION.

A SUMMARY of some of the preliminary scientific results of the Scottish National Antarctic Expedition appeared in the August number of the *Scottish Geographical Magazine*, and this has now been issued in the form of a corrected reprint, from the office of the expedition in Edinburgh. The pamphlet contains an introduction by Mr. W. S. Bruce, the leader of the expedition, a paper on the bathymetrical survey of the South Atlantic Ocean and Weddell Sea, also by Mr. Bruce, and short papers on the deep-sea deposits, by Dr. Harvey Pirie, on the meteorology of the expedition, by Mr. Mossman, and on Diego Alvarez, or Gough Island, by Mr. Rudmose Brown. An account of part of the work of the expedition has already appeared in these columns (NATURE, March 2).

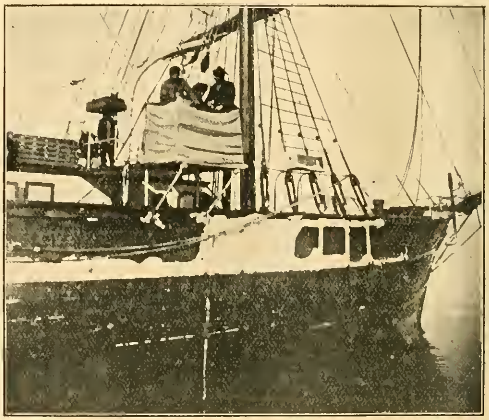

FIG. 1.—*Scotia* sounding in supposed Ross Deep 68° 32′ S., 12° 49′ W., on March 23, 1904.

The most important facts brought to light in the course of the sounding and exploring work are those connected with the discovery of Coats Land, and the final removal from the map of the "Ross deep," in which the *Erebus* and *Terror* reported 4000 fathoms no bottom. The supposed coast-line of the Antarctic continent south-east of the Weddell Sea has hitherto been placed in about 80° S. lat., probably because of the belief, to which certain temperature observations seemed to give support, that Ross's sounding was really correct. The *Scotia* discovered Coats Land in 72° 25′ S., 17° 27′ W., and skirted the coast for 150 miles. Within 2 miles of the assigned position of Ross's sounding (68° 32′ S., 12° 49′ W.) the *Scotia* touched bottom in 2660 fathoms, and the sounder brought up a large sample of blue mud. "Thus," as Mr.

Bruce puts it, "after more than sixty years of doubt, Ross Deep was removed from the map, and all the bathymetrical maps based upon this sounding were no longer of any practical use. It is interesting to contrast the methods of sounding employed on the two occasions by comparing Mr. Bruce's photographs, which we reproduce, with the illustration given in Ross's book. Another discovery of great importance is that of a ridge showing a continuation of the "South Atlantic rise" a thousand miles further south than it was previously known to exist. There is thus a ridge "extending in a curve from Madagascar to Bouvet Island, and from Bouvet Island to the Sandwich Group, whence there is a forked connection through the South Orkneys to Graham's Land, and through South Georgia to the Falkland Islands and South American continent." . . . "Antarctica, South America, and Madagascar, become connected with one another in a most direct manner by this 'rise.'" Basing his arguments on these discoveries, Mr. Bruce strongly opposes Sir Clements Markham's theory, set forth in his recent address to the Royal Geographical Society, that the Antarctic area consists of two land masses of unequal size, Victoria Land and Edward VII. Land, separated by a great barrier of ice, and of two seas extending far to the south, the Ross Sea and the Weddell Sea.

Fig. 2.—*Scotia* beset in heavy ice in 74° 1′ S. off Coats Land. The shearlegs show the position of the baited trap in 161 fathoms.

Fig. 3.—Meteorological Instruments at Scotia Bay.

The papers by Dr. Harvey Pirie and Mr. Mossman contain many points of great interest, although in the nature of things the material collected requires further elaboration, and comparison with that of the other expeditions, before its full value becomes apparent. Dr. Harvey Pirie's observations give much additional information bearing on the variations in the relative amounts of diatoms in the surface waters and in the deposits, and the remarkable differences in the meteorological values for 1903 and 1904 enable Mr. Mossman to draw many important conclusions as to the factors controlling the climate. Mr. Rudmose Brown gives an interesting account of an island which has, curiously enough, remained unexplored until now, although it lies almost on the track of sailing-ships outward bound *viâ* the Cape of Good Hope.

THE PERCY SLADEN EXPEDITION IN H.M.S. SEALARK.

I HAVE just received the accompanying communication from Mr. Stanley Gardiner, bringing the account of his expedition to September 12, the date of his letter. The letter is written from Coetivey. I may remind readers of Nature that his former communications appeared in the issues of August 10 and October 5. A. Sedgwick.

Zoological Laboratory, Cambridge, October 23.

Since my last letter Cooper and I have had a tour round the reefs of Mauritius, and have for the last three weeks been working between the latter island and the Seychelles Group. The Mauritius reefs vary from fringing to barrier, the best example of the latter being at Grand Port, where it is four miles from the land. It has there a few small islets of somewhat metamorphosed coral-rock, varying up to 40 feet high. At first it seemed as if they might have been formed by hurricanes and blown sand, but we discovered the same rock in the immediate vicinity overlying a basalt, 70 feet above the water. The present islets probably represent the remains of a considerable island, elevated for at least 100 feet, extending along that part of the barrier reef.

Leaving Mauritius on August 21, we had three days' dredging and sounding off its reefs. The contour is the same as that off atoll-reefs, a gradual slope to 40 fms. (fathoms), succeeded by a steep to 150 fms., then tailing off in five miles to 1000 fms. The bottom at 150 fms. was covered by heavy blocks of coral from the reef above. At 300 fms. we found shell and small pieces of coral, and further out a bottom of bare coral mud, sweepings from the reef and land.

Between Mauritius and Cargados there was a depth of 1062 fms., there being no marked connecting ridge, though the bottom tails off very gradually from each bank. At Cargados we remained for six days, examining the reefs and islets, and dredging. It is a crescentic-shaped surface reef, 31 miles long, on the south part of the Nazareth Bank, which is roughly 220 miles long by 60 broad, with an average depth of 33 fms. The land is of coral rock with no signs of elevation, and is a great breeding resort for tern. It is covered with guano, owing to which the land flora is very scanty, only 18 different plants being found. Naturally land animals were scarce, but 42 insects were secured, four-fifths from the guano.

Cooper for the most part took the dredgings, and he reported to me that he found near Cargados "a wonderfully constant depth of 30–35 fms. over the body of the bank, while towards its western edge there is a slight but uniform rise to 27 fms., thus suggesting an incipient atoll with its eastern side slightly tilted up above its western. Over the plateau, where 30 hauls were made in different directions, the bottom was either coral-rubble, white sand, shell-rubble, or weed. The three latter occurred only in the central parts of the bank, while the coral-rubble, though also found there, alone formed the raised edge of the western side, being mostly in the form of large lumps. From this rubble, which is of a bright red colour due to an encrusting nullipore, we obtained a rich variety of animal life, nearly all forms tinted with red. The absence of living corals from the rim as well as from the plateau in all depths over 20 fms. was a noticeable feature." About 25 different species of algæ (not lithophytes) were dredged, several from 40–50 fms. on the outer slope, though none have so far been secured from more than 60 fms.

In the channel midway between Nazareth and Saya de Malha banks we found a depth of 222 fms., the connection being a ridge rapidly tailing off on its western side to more than 800 fms. Saya de Malha itself really consists of three banks, a northern, a very large central, and a small south-eastern. The north bank we found to be separated by a channel of 636 fms. from the central, while the depth between the latter and the southern bank is only 130 fms. All are of more or less atoll form, but the south side of the central bank differs from all other parts of the same banks and from the Nazareth Bank in tailing off *very gradually* from 65 fms., the general depth in its centre, to 200 fms. The area in this part beyond 120 fms., which is to some degree protected from the prevailing south-east winds and currents, formed a rich collecting ground, the bottom being composed of a white rubble of bivalve and sea-urchin shells, evidently all swept off the shallower bottom above. From 80 to 100 fms., where it is more exposed, the bottom is hard, being swept bare by the currents, but still further north at 60 fms., where the eastern edge of the bank has only 10–20 fms. of water, is soft mud with casts of pelagic foraminifera. A considerable number of dredgings were taken at depths above 20 fms., and fair collections have been obtained. Only the regular deep-living corals were secured, but two hauls at 26 and 29 fms. gave between them more than 20 species of corals, typical of shallow reefs. To the north of the banks we dredged between 300 and 500 fms., the bottom being of the usual character at such depths off coral reefs, though with rather more rubble.

Leaving the Saya de Malha banks we ran a line of soundings to the shallow bank, which surrounds the Seychelles, the greatest depth found being 961 fms. Thus our soundings prove the existence of a crescentic-shaped ridge, 1100 miles long, with less than 1000 fms. of water, arising on either side from a general depth of 2200 fms.

Now we are at Coetivy, the most southerly island of the Seychelles Group. It is an atoll bank with a large island to the east, where we shall camp for ten days, while the ship goes to the Seychelles for coal. On her return we propose to examine the line connecting the Seychelles to Madagascar. J. STANLEY GARDINER.

September 12.

SOME CHARACTERISTICS OF AMERICAN UNIVERSITIES.[1]

THE total amount of private benefactions to university education in the States during the last thirty years reaches the amazing figure of forty millions sterling; and this is quite apart from the large annual appropriations made by the Federal Government and by the State Governments for technical colleges and State universities. The total amount contributed by private benefactions in the same period in these islands was about five millions.

The number of professors, lecturers, and other teachers in the American universities and institutions of university standing is very little short of the total number of university students in the British Isles; the figures are respectively 17,000 and 20,500.

A large and increasing number of the greatest industrial and commercial firms in America restrict their highest posts to college graduates. In Montreal two great railway companies the Canadian Pacific and the Grand Trunk have just clubbed together to establish and endow in McGill University a department of railway engineering for training the first-rate staff of officials, which they feel to be indispensable to the rapid extension of their lines in the great north-western territories now awaiting development. Of our own industrial leaders, it would be safe to say that at least nine out of ten would regard a college training as an absolute disqualification.

The vigour of the professional schools is to be explained by two features which differentiate them from our own:—(1) The presence of a culture element; (2) the close and almost organic connection between academic and industrial life.

(1) Where a professional or higher technical school is established in England, the tendency is to make it purely technical, to banish all literary studies, and confine the student's attention strictly to scientific study directly bearing on his future profession. In America a broader view is taken.

The great Morrell Act for agricultural and mechanical colleges was thus expounded by its author:—"These colleges were not established for the sole purpose of teaching agriculture. It was never intended to force the boys of farmers going into these institutions so to study, that they should all come out farmers, but to give them an opportunity to do so if they saw fit. Secondly it was a *liberal education* that was proposed. Classical studies were not to be excluded, and must therefore be included."

But further, the technical course itself in the great majority of cases includes a culture element, supplied not by Latin and Greek, but by French or German, history, civics, and economics. The Massachusetts Institute of Technology in Boston, the greatest school of the kind on the Continent, the Pratt Institute (Brooklyn), the Armour Institute (Chicago), all make literary studies of this kind an indispensable part of the curriculum for their diplomas. The same is true of the great Guelph College of Agriculture in Ontario: French, German, and English literature have to be studied before the student can graduate as B.S.A. of the University of Toronto; and the reason was well put by the principal:—"It is not sufficient that our graduates should know their professional work, they must have some knowledge of their fellow-men and power of holding their own and of presenting their subject to the educated public, which a purely technical training cannot give." These are the words of a remarkable man who found Guelph in 1884 on the verge of extinction, and in twenty years has raised it to a position of almost undisputed primacy among the agricultural colleges of the continent, and transformed thereby the agricultural industry of central Canada.

(2) Both professors and students are in the closest touch with the industry which the school is intended to feed. The former are not merely permitted, but encouraged to take private outside work. The latter are required to spend some part at least of their vacations in working in mines, engineering works, on farms, &c., as the case may be, and their reports on the work thus done contribute

[1] Abridged from an address delivered before the Guild of Graduates of the University of Wales at Aberystwyth, by Principal H. R. Reichel.

to form the professors' estimate of their fitness for the degree.

The universal length of the undergraduate course is four years, not three as with us; and I am bound to say the lengthened period seems to me to have a decided advantage in avoiding hurry and encouraging maturity of growth. For several years the doubt has been growing in my mind whether our qualifying period of three years can be regarded as satisfactory. We owe it, no doubt, to the habit of mind inherited from the old London University of regarding ability to pass a written examination as the true test of training. From this incubus the American university is almost wholly free. A student gets his degree for the regular work he does throughout his university course, and though there is a test at the end, that test hardly ever takes the form of a cumulative examination in all he has been studying for two or three years; often it is a thesis. The effect of this on the course of study is very marked.

Post-graduate study is of comparatively recent growth in the States, and largely the outcome of the foundation and development of the Johns Hopkins University.

Like the Owens College in Manchester, Johns Hopkins owes its origin to the philanthropy of a wealthy merchant of Welsh descent. Its peculiar character, however, is due to the academic prescience and statesmanship of its first president. He saw that there were plenty of universities and colleges of the ordinary undergraduate type, and that what the country really needed was a university for "graduate study," which at that time could only be secured by going to Germany.

The method of teaching is based on that of the German seminar, of which it has adopted the name, but it provides for more constant and systematic intercourse between professor and student. While the German seminar meets weekly, the American meets every day, and the student receives far more individual attention. The course again is more exacting, the minimum length being three years, and the average four and a half, starting, be it remembered, from the completion of the B.A. degree. The aim is to train in methods of original investigation—in short, as it was well put to me by one of the professors, "to transfer to literary studies the methods of higher work in science." The work is based on the preparation of the student's dissertation for the doctorate. At every stage, first in outline and subsequently in complete form, the dissertation is discussed section by section, chapter by chapter. Each department of study has its own seminar room furnished with a departmental reference library. The arrangement is not that of the lecture theatre, which implies an orator and an audience, but rather that of the committee room with a chairman and a ring of debaters. The class, which would never exceed from twelve to fifteen, sits at an oblong table, the professor, so to speak, occupying the chair of the meeting at one end. Round the walls at their backs are the shelves containing books of reference, often running to several thousand volumes, and these, it should be noted, are quite independent of the central university library.

This seminar study was at first the sole, and is still the main, work of the university, and that which has made the name of Johns Hopkins famous throughout the civilised world. An age more given to omens might have seen in the remarkable fact that in the gigantic conflagration which recently swept away the centre of the city of Baltimore, the university was the only public institution the buildings of which escaped scot free, a tribute of the powers of nature to the unique position it holds in American academical life. Its influence on higher study through the whole North American continent has been rapid and profound. It is not merely that a large number of distinguished specialists has been produced whose labours have raised the level of American learning; post-graduate study has become the ambition of the American university, and more and more is being accepted as that which differentiates it from the mere college. There are few universities now which have not their seminar rooms and departmental libraries, though it must be admitted that in many cases these are at present only utilised for undergraduate study of the third and fourth years. But the growth in post-graduate work since Johns Hopkins was founded has been fairly staggering. In 1871 there were only 198 post-graduate students in the States; twenty-five years later the number had risen to 4919, or very nearly one quarter of the total number of university students of all classes in the British Isles.

The great bulk of those who win the Johns Hopkins doctorate naturally become university professors and lecturers. At the same time there is a rapidly increasing demand for them from the high schools, which are all organised on the basis of specialist teaching in each department. The evidence, both at the schools and the universities, supports the view that the Ph.D. candidate for a school post would have the advantage over a B.A. who had also been through a course of training in teaching, and would command a higher salary, and that this tendency is on the increase. It is felt that the man whose knowledge is deepest is likely to make the best teacher, and that lack of pedagogic skill at the start will be made up for in the long run by greater inspiration.

The system of our own older universities—at least of Oxford—is, it must be confessed, less favourable to post-graduate work. The explanation is to be found largely in the difference of the undergraduate course. The American university has no "honours" schools for the initial degree in which the energies of the best men are devoted rather to amassing the results of other people's investigations over an immense area than to cultivating the power of acquiring knowledge by their own. One of my fellow commissioners, who had examined at Cambridge in the law tripos, and bears a name of European reputation, told me he was often perfectly "horrified" by the amount the young men knew; such a mass of knowledge must have a most deadening effect on intellectual vigour. Thus, while the actual attainment at the initial degree is by no means so high as at Oxford and Cambridge, at all events for the best students, there is a far truer conception of learning, and an enormously larger proportion of men go on to higher work and research. In my visits to the universities the question was repeatedly asked of me, "What kind of men should we select for the Rhodes scholarships?" My answer has always been, "By all means, send us graduates. Undergraduates will do Oxford little good, and may get out of touch with American life; graduates will gain a wider experience without being de-americanised. Nothing, at the same time, would do so much for the revival of higher study at Oxford as a steady supply of picked graduates of an inquiring type." "But does Oxford want graduates?" has been the usual reply. "The experience of many men we know who have been there is that it is practically impossible to get assistance for post-graduate work; after a short trial they have generally gone on to Germany." The justice of the criticism it is difficult to question. Though the University of Oxford has created special post-graduate degrees in order to attract graduates of other universities for advanced study or research, the Oxford college with its pot-hunting instincts stands in the way. It makes, or thinks it makes, its name by the number of first classes won by its undergraduates, and will, therefore, give no encouragement to the higher learning which our Philistine upper class neither understand nor care for. I have known a case where the whole tutorial influence of a college was used to prevent one of its scholars competing for a university prize essay involving original research. It was not denied that the work might be intellectually better for him, but then it might endanger his "first." The scholar, I am glad to say, had the strength of mind to take his own line, and gained the prize.

Let me conclude with a word about the ideals of the students and their attachment to their old college or university. I have said that the course is never less than four years; when I add that there are hardly any scholarships and that a large proportion of the students are distinctly poor, you will doubtless ask how they manage to do it? This brings me at once to what I unhesitatingly affirm to be the most admirable feature of life on the other side of the Atlantic, whether in the States or in Canada, viz. the entire absence of the feeling that honest work of any kind can be derogatory to an educated man. The American and Canadian student whose friends

cannot afford to keep him at college, pays his way either by working during the long vacation in all sorts of manual employment or by rendering what we should regard as menial services to his fellow-students during term time, much like the old "servitors" at Oxford and Cambridge. Nor does this create any social barrier. At one university visited by some of my Mosely colleagues they were waited upon during the college dinner by some very intelligent looking young fellows, and found on inquiry that these were students. Somewhat surprised at this, one of the party asked if this would not tell against them socially. "Not in the least," was the answer. "That man over there is president of one of the chief debating societies; that other is one of our best athletes and much looked up to." It is the same in the women's colleges. At Vassar one girl keeps a bicycle cleaning shop; they act as room-tidiers, clean shoes, &c. In Canada I was informed that at Queen's University, Kingston, no less than 70 per cent. of the men students earn their fees and maintenance for the coming session by working through the summer on farms, on the railway, in mines, river steamboats, &c. The fact is, the Transatlantic youth is rather proud of being able to earn his own living; it makes him feel himself more of a man, and it is not at all uncommon for the son of rich parents to take work in this way for the sense of independence it brings. It is a fine spirit, and makes one blush when one thinks how very different a reception such conduct would probably meet with over here.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The committee for the supervision of instruction in geography has appointed Dr. A. J. Herbertson, director of the school of geography, for the remainder of the term of five years for which the grants to the school of geography have been voted. A syllabus of the examination for the diploma in this subject has been issued, which includes regional geography, climatology and oceanography, geomorphology, historical geography, and surveying.

The delegates of the common university fund have elected Mr. G. W. Smith, New College, to the biological scholarship at Naples for the year 1905–6.

Mr. M. H. Godby has been elected to a Dixon research scholarship in chemistry at Christ Church.

CAMBRIDGE.—An interesting insight into the way the university is governed is given by the following figures. A careful analysis of the poll-book of the recent vote on "compulsory" Greek gives the following results:—(1) Of the residents, 288 voted in favour of the recommendation that Greek should no longer be compulsory in the previous examination; 240 voted against the recommendation—majority of residents in favour of the recommendation, 48. (2) Of the total number of members of the senate who voted, residents and non-residents included, 1591 were laymen, 1021 were clergymen. Of the laymen, 923 voted in favour of the recommendation; 668 voted against it—majority of laymen in favour of the recommendation, 255. Of the clergymen, 132 voted in favour of the recommendation; 889 voted against it—majority of clergymen against the recommendation, 757.

The report on the proposed diploma of forestry was discussed on Thursday, November 2. Among the speakers were the professor of geology, the professor of botany, the secretary of the financial board, and the master of Gonville and Caius College. The proposal was warmly welcomed.

The State medicine syndicate reports that last year seventy-one candidates presented themselves for the diploma in public health, and that twenty-four candidates entered for the diploma in tropical medicine and hygiene, sixteen of whom were successful.

The following have been nominated examiners for the natural science tripos in 1906:—in physics, Mr. R. T. Glazebrook and Mr. C. T. R. Wilson; in chemistry, Mr. H. O. Jones, and Mr. H. B. Baker, Oxford; in mineralogy, Prof. Lewis, and Mr. H. L. Bowman, Oxford; in geology, Mr. P. Lake and Dr. F. A. Bather; in botany, Mr. A. C. Seward, and Mr. A. G. Tansley, of University College, London; in zoology, Mr. A. Sedgwick, and Prof. MacBride, of Montreal; in physiology, Mr. W. M. Fletcher, and Prof. T. G. Brodie, of the Brown Institute; in human anatomy, Dr. Barclay Smith, and Dr. A. Robinson, of Birmingham University.

The Vice-Chancellor announces that Sir Archibald Geikie will, on behalf of the board of geographical studies, deliver a public lecture in the Sedgwick Museum on November 21, at 5 p.m., on "The Evolution of a Landscape." On the evening of the same day, and at the same place, Dr. C. Hose, of Sarawak, will lecture on Borneo.

The next combined examination for sixty-two entrance scholarships and various exhibitions at Pembroke, Gonville and Caius, King's, Jesus, Christ's, St. John's, and Emmanuel colleges will be held on Tuesday, December 5, and following days, commencing at 9 a.m. on December 5. Mathematics, classics, and natural sciences will be the subjects of examination at all the above-mentioned colleges. Scholarships and exhibitions will also be offered for history, for modern languages, and for Hebrew at some of the colleges. A candidate for a scholarship or exhibition at any of the seven colleges must not be more than nineteen years of age on October 1, 1905. Forms of application for admission to the examination at the respective colleges may be obtained as follows:—Pembroke College, Mr. W. S. Hadley; Gonville and Caius College, the Master; King's College, Mr. W. H. Macaulay; Jesus College, Mr. A. Gray; Christ's College, Rev. J. W. Cartmell; St. John's College, Dr. Donald MacAlister, Dr. J. R. Tanner, Mr. E. E. Sikes; Emmanuel College, the Master; from any of whom further information respecting the scholarships and other matters connected with the several colleges may be obtained. The forms of application must be sent in on or before Tuesday, November 28.

MR. F. S. PINKERTON has been appointed professor of applied mathematics at the University College of South Wales, Cardiff.

BY the will of Mr. J. E. Williams, of Chester, who died on July 15, a legacy of 10,000*l*. is bequeathed to the University of Wales, the income to be used in founding new scholarships and prizes in his name, to be held upon certain terms and conditions. In the event of the University of Wales not accepting the legacy within six months, the same is to be paid to the trustees of the University College of North Wales at Bangor upon the same conditions. He also bequeathed 10,000*l*. to the University College of North Wales at Bangor upon the same conditions, and 2000*l*. for the building fund of this college.

AT the last meeting of the council of the University of Birmingham, the Vice-Chancellor (Alderman C. G. Beale) in the chair, the Chancellor (Mr. Chamberlain) announced that a friend of the university, who desired to remain anonymous, had promised a donation of 50,000*l*., the amount to be applied towards the completion of the new buildings at Bournbrook. The council desired the Chancellor to convey its best thanks to the generous donor for his munificent gift. This is the fourth amount of 50,000*l*. already contributed to the university endowment fund, the other sums having been received from Mr. Andrew Carnegie, Sir James Timmins Chance, and an anonymous donor. The total fund is about 450,000*l*., to which must be added annual contributions from the City Council (6000*l*. per annum), and 500*l*. each from the county councils of Staffordshire and Worcestershire. The council has already approved of expenditure upon the site and buildings amounting to about 280,000*l*., in addition to upwards of 80,000*l*. on equipment. It is hoped that a formal opening of the new buildings may be possible in about eighteen months' time.

THE Board of Education has issued the following list of candidates successful in this year's competition for the Whitworth scholarships and exhibitions:—(1) *Scholarships*, 125*l*. a year each (tenable for three years): H. Topham, Grantham; C. W. Price, Devonport; W. F. Paffett, Portsmouth; R. W. Bailey, Goodmayes (Essex). (2) *Exhibitions*, 50*l*. (tenable for one year): W. White, Southsea;

A. E. Humber, Portsmouth; G. Lees, Southsea; A. Ward, London; A. W. Sawyer, London; C. E. G. House, Chatham; H. Schofield, Halifax; J. M. Robertson, Pembroke Dock; W. E. G. Sillick, Devonport; J. A. Cormack, Glasgow; F. Clements, Chesterfield; B. J. Cole, Devonport; P. W. M. Sparey, London; S. Lees, Manchester; B. H. Penn, Bedford; W. H. Stock, Swindon; W. R. Sinclair, Newcastle-on-Tyne; M. Bell, Bensham, Gateshead; T. H. Essery, Devonport; S. H. Warren, Devonport; A. R. Valon, London; G. R. Wilkinson, Oldham; A. D. Johnston, jun., South Shields; W. C. A. Bowles, London; A. L. Bird, Cambridge; T. N. Adlam, Trowbridge; J. Bedford, Chingford; P. P. Smart, Wolverton; C. L. Gransden, Chatham; W. F. Brown, Birkenhead.

THE following list of successful candidates in this year's competition among science students for Royal exhibitions, national scholarships and free studentships has been issued by the Board of Education:—*Royal exhibitions:* Arthur B. Middleton, Bradford, Manchester; William White, Southsea; Alfred E. Humber, Portsmouth; George Lees, Southsea; Frederick E. Pollard, Eastwood, Notts; James L. Kent, Portsmouth; Frank Fielden, Halifax. *National Scholarships for Mechanics (Group A):* Arthur T. Wall, Plymouth; Arthur Cannon, Plymouth; William E. Dommett, Southsea; Herbert J. London, London; Charles E. G. House, Chatham; William E. G. Sillick, Devonport. *Free Studentships for Mechanics (Group A):* Charles L. Gransden, Chatham; Harford G. Stephens, Leicester. *National Scholarships for Physics (Group B):* John M. Strang, Glasgow; Frederick Reid, Glasgow; John W. Waters, Chatham; Dudley Orson-Wood, Chiswick; George F. Hemens, London; William F. Higgins, London; Walter C. M. Pettingill, Leeds. *Free Studentships for Physics (Group B):* Frederick J. Harlow, Whitstable; Edward F. Pattenden, Whitstable. *National Scholarships for Chemistry (Group C):* Harry F. V. Little, London; Tom Thornley, Blackburn; Samuel Lamb, Bradley, Bilston; Alan C. Webber, Brighton; John H. Jennings, Plymouth; Robert O'F. Oakley, London. *Free Studentships for Chemistry (Group C):* Archibald Wise, Plymouth; Charles S. Garland, London. *National Scholarships for Geology (Group E):* John W. Maxfield, Burnley; Ernest Proctor, Burnley; James Mitchell, Burnley.

THE annual general meeting of the Association of Teachers in Technical Institutes was held at the Birkbeck College, London, on November 4. The association, which was founded a year ago, already has a membership of 300 exclusive of the Association of Teachers of Domestic Sciences, which is affiliated with it. Mr. W. J. Lineham, the president, was in the chair, and moved the adoption of the report of the council, which was subsequently agreed to. The council recommends in the report that meetings of teachers in provincial technical institutes be called to lay the claims of the association before them directly. A resolution was passed instructing the council to call meetings of the teachers in provincial technical institutes and to consider the following matters with full powers to act therein:—(*a*) The formation of local or provincial branches of the association; (*b*) joint action or federation with the West Riding Association of Teachers of Science, Art, and Technology, the Federation of London Teachers, and other bodies of teachers. One of the most important matters discussed during the year has been the registration of teachers. A scheme has been drawn up by the council, and a circular has been issued to members pointing out its importance upon the future *status* and professional position of teachers in technical institutes. A scheme for registration has already been formulated by the teachers of domestic science. The council recommends that steps be taken at an early date, by deputation or otherwise, to urge upon public examining authorities the importance of securing closer connection between the examiner and the teacher. Various amendments to the constitution and rules were decided upon, and the title of the association was changed to that of "The National Association of Teachers in Technical Institutes," and it was resolved that its officers be a president, two vice-presidents, an hon. secretary, and an hon. treasurer. Mr. Lineham was elected president for the ensuing year.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, October 27.—Prof. J. H. Poynting, F.R.S., president, in the chair.—The theory of phasemeters: Dr. W. E. **Sumpner.** The author shows in the paper that the theory of the instruments is the same whether they contain iron or not, and however the coils may be arranged; that they can be calibrated by direct-current methods, although for use on alternating-current circuits; and that a new type of instrument, containing iron, conforms to the theory given. The main results of the investigation are:—(1) Phasemeters for multi-phase circuits are all equally accurate on balanced loads provided they have been correctly calibrated and possess no faults due to purely mechanical causes. Their accuracy is not affected by variations in wave-form or in current-frequency. (2) Phasemeters can be simply and accurately calibrated for balanced loads by means of a direct-current method of test. (3) The error of phasemeters on unbalanced circuits is generally serious for loads which are badly out of balance. The error, like that of a wattmeter, increases rapidly as the power-factor of the load diminishes. It can only be reduced at the expense of complication in the instrument, by increasing the number of coils used in the fixed and moving systems, and by arranging the coils and magnetic circuits to be symmetrical in regard to one another.—Apparatus designed for measuring the coronal radiation during an eclipse: Prof. H. L. **Callendar.** A preliminary test of the apparatus with the thermopile directly exposed to radiation of known intensity showed a deflection of nearly 25 cm. for one-thousandth of a calorie per sq. cm. per min., so that radiation one-millionth of full sunshine could be detected with certainty without using a mirror. When placed in the focus of the telescope used, radiation one thousand times smaller than this could be observed, so that even if the intrinsic heat-radiating power of the corona were only one ten-millionth of the solar surface it could still be measured to within 1 per cent. The essential point in the observations was to eliminate the variable effects of atmospheric radiation, for which a differential method of observation with the two halves of the pile was particularly suitable. In taking observations on the corona, the motion of the moon during totality was made use of to define the exact area of the corona corresponding to the differential reading. At the commencement of totality, the thermopile being centred on the sun, the inner corona on the eastern limb would be fully exposed, while on the western it would be partly covered by the moon. At the end of totality the reverse would be the case. The difference of the readings would correspond to the radiation of the strip of the inner corona uncovered by the motion of the moon between the two readings. The area of the strip of corona considered could be accurately determined from the times at which the readings were taken.

PARIS.

Academy of Sciences, October 30.—M. Troost in the chair.—Two hæmatozoa of the partridge and turkey: A. **Laveran** and M. **Lucet.** The first of these was the cause of the death of 97 out of 100 Hungarian partridges imported into France. Its appearance and mode of division corresponded with *Haemamoeba relicta*, a parasite which has been known to be responsible for epidemics in many birds, but not hitherto of the partridge. The other parasite, found to be the cause of perityphlo-hepatitis in the domestic turkey, appears to belong to a new species, and is named *Haemamoeba Smithi.*—A criterion for the application of the Gompertz-Makeham mortality law: Charles **Goldziher.** The application of this law depends absolutely on the regularity of the original series, but, so far, an exact criterion for the exactitude of the limits between which this application is possible has been wanting. This is worked out in the present paper.—On the composition of the hydrochloroferric colloid with respect to the amount of hydrochloric acid present in the suspending liquid: G. **Malfitano.** By increasing the concentration of the medium in hydrochloric acid, the colloid tends to approximate to the composition $H(Fe_2O_6H_6)Cl$.—Observations relating to some india-rubber plants: A. **Chevalier.** Whatever may be the family to which a caoutchouc belongs, its richness

in india-rubber is an individual peculiarity. The yield may be very different in two individuals of the same age and of the same size, living side by side, and having the latex extracted at the same time. The influence of different kinds of light radiations on the migration of the albumenoids in the wheat grain: J. **Dumont.** It was found that the radiations which have the greatest effect on the migration of the albumenoids in the wheat grain are precisely those which act the least on the chlorophyll function.—On the mechanical work furnished by windmills: M. **Ringelmann.** The windmill studied was of the type used in agriculture for raising water. Automatic records were made of the velocity of the wind, the number of turns of the vane, and of the water lifted. A table of results for different velocities of the wind is given, and from this the work obtainable from a windmill can be calculated.—The accessory glands to the silk-producing apparatus of the larvæ of *Io Irene*: L. **Bordas.** The liquid or slightly viscous substance secreted by the accessory glands serves to agglutinate or unite the two silk threads. It is possible, also, that it exerts a chemical action on the threads, causing them to harden rapidly.—On the existence of strata containing Clymenia in the central plateau, Morvan: Albert **Michel-Lévy.**—On the dissymmetry of the loss of electricity in mountainous countries: the comparative *rôles* of height and relief: MM. Bernard **Brunhes** and Albert **Baldit.** At the summit of a mountain the rate of loss of volts is greater for negative than for positive electricity. These results serve to show why several authors have been led to think that passing from the plain to a mountain leads to a great exaggeration of the loss of negative electricity.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 9.

MATHEMATICAL SOCIETY, at 5.30.—Annual General Meeting—The Continuum and the Second Number-class: G. H. Hardy.—On the Arithmetical Nature of the Coefficients in a Group of Linear Substitutions of Finite Order (second paper): Prof. W. Burnside.—On the Asymptotic Value of a Type of Finite Series: J. W Nicholson.—On an Extension of Dirichlet's Integral: Prof. T. J. I'A. Bromwich.—(1) On Improper Multiple Integrals; (2) On the Arithmetic Continuum: Dr. E. W. Hobson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Inaugural Address: John Gavey, C.B.

FRIDAY, NOVEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 5.—(1) Observations of the Satellite of Neptune from Photographs taken between Nov 11, 1904, and April 15, 1905; (2) Micrometric Measures of Double Stars made with the 28-inch Refractor in the Year 1904: Royal Observatory, Greenwich: Communicated by the Astronomer-Royal.—(1) On the Secular Acceleration of the Earth's Orbital Motion: (2) On the Ptolemaic Eclipses of the Moon recorded in the Almagest: P. H. Cowell.—Observations of Phenomena of Jupiter's Satellites made at Windsor, New South Wales, in the Years 1900 and 1902: John Tebbutt.—On the Corrections to Hansen's "Tables de la Lune," as deduced by Mr. Cowell: E. Nevill.

PHYSICAL SOCIETY, at 8—The Question of Temperature and Efficiency of Thermal Radiation: J. Swinburne.—Note on Constant-Deviation Prisms: T. H. Blakesley.

MALACOLOGICAL SOCIETY, at 8.—(1) Descriptions of New Species of Drymæus, Amphicyclotus, and Neocyclotus from Central and South America; (2) Description of a New Species of Achatina from Mashonaland: S. I Da Costa.—On a Collection of Land and Freshwater Shells from Sumatra with Descriptions of New Species, part i.: Rev. R. Ashington Bullen On a New Species of Oliva: F. G. Bridgman.—On the Anatomy of *Ensis macha* and *Solen fonesii* and *S. viridis*: H. H. Bloomer.

TUESDAY, NOVEMBER 14.

INSTITUTION OF CIVIL ENGINEERS, at 8.—On Waterways in Great Britain: J. A. Saner.

ZOOLOGICAL SOCIETY, at 8.30.—On the Papillary Ridges in Mammals, chiefly Primates: Dr. Walter Kidd.—On a Collection of Mammals brought home by the Tibet Frontier Commission: J. Lewis Bonhote.—Note on the Geographical Distribution of the Okapi: Dr. Einar Lönnberg.—Notes on Goral found in Burma: Major George H. Evans.—The Mammals of Crete: Dorothea M. A. Bate.

MINERALOGICAL SOCIETY, at 8.—The Determination of the Angle between the Optic Axes of a Crystal in Parallel Polarised Light: Dr. J. W. Evans.—(1) On a Tabular Crystal of White Diopside; (2) On a Carlsbad-twin of Albite: Prof. W. J. Lewis.—Note on the Crystallisation of Drops, especially of Potash-Alum: J Chevalier. Note on the Formation of Gypsum Crystals in a Disused Well at Chemical Works: C. J. Woodward.—(1) Ilmenite from the Kollergraben, Binnenthal; (2) On a New Red Cubic Mineral; (3) On Seligmannite, Marrite, and Lengenbachite from the Lengenbach Quarry; (4) On Anhydrite and other Minerals found in the White Dolomite of the Simplon Tunnel: R. H Solly.

WEDNESDAY, NOVEMBER 15.

SOCIETY OF ARTS, at 8.—Opening Address of the Chairman of the Council, Sir Owen Roberts.

ENTOMOLOGICAL SOCIETY, at 8.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—The Rainstorm of August 24–26, 1905, in Co. Dublin and Co. Wicklow: Sir J. W. Moore.—The Aquameter: Dr. W. B. Newton.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Exhibition of Microscope Slides of Tsetse-Fly Dissectinns, Trypanosomes, etc.

THURSDAY, NOVEMBER 16.

ROYAL SOCIETY, at 4.30.—The Physical and Chemical Properties of Iron Carbonyl: Sir James Dewar, F.R.S., and H. O. Jones.—The Transit of Ions in the Electric Arc: A. A. Campbell Swinton.—First Photographs of the Canals of Mars: Prof. Percival Lowell.—On the Laws of Radiation: J. H. Jeans.—The Pressure of Explosions. Experiments on Solid and Gaseous Explosives: J. E. Petavel.—On Newton's Rings formed by Metallic Reflection: Prof. R. C. Maclaurin.—The Accurate Measurement of Ionic Velocities: Dr. R. B. Denison and Dr. B. D. Steele.

CHEMICAL SOCIETY, at 8.30.—Silicon Researches, Part ix., Bromination of Silicophenyl Imide and Amide, and Formation of a Compound including (SiN): J. E. Reynolds.—Condensation of Ketones with Mercury Cyanide: J. E. Marsh and R. de J. F. Struthers.—Application of the Microscopic Method of Molecular Weight Determination to High Boiling Solvents: G. Barger and A. J. Ewins.—Green Compounds of Cobalt produced by Oxidising Agents: R. G. Durrant.—Synthesis of Tertiary Menthol and of Inactive Menthene: W. H. Perkin, Jun.—Optically Active Reduced Naphthoic Acids, Part i., Dextro-$\Delta^{(2 \text{ or } 3)}$-dihydro-1-naphthoic Acid: R. H. Pickard and A. Neville.

LINNEAN SOCIETY, at 8.—Contributions to the Embryology of the Amentiferæ: Dr. Margaret Benson, Elizabeth Sanday and Emily Berridge.—On the Ears of certain Sharks: Prof. Chas. Stewart, F.R.S

FRIDAY, NOVEMBER 17.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—The Seventh Report of the Alloys Research Committee; On the Properties of a Series of Iron Nickel-Manganese-Carbon Alloys: Dr. H. C. H. Carpenter, R. A Hadfield, and P. Longmuir.

CONTENTS.

THURSDAY, NOVEMBER 16, 1905.

"*MATHEMATICS*" *APPLIED TO CHEMISTRY.*

Researches on the Affinity of the Elements, and on the Causes of the Chemical Similarity or Dissimilarity of Elements and Compounds. By Geoffrey Martin. Pp. xii+287. (London: J. and A. Churchill, 1905.) Price 16*s.* net.

THE word "mathematics" has been placed in the title of this review in inverted commas, because, although the mathematical formulæ employed appear to be formally correct, the application of mathematical formulæ to the data collected in Mr. Martin's work appears to the reviewer to be unjustified. To demonstrate this a sketch of Mr. Martin's scheme is necessary.

Mr. Martin's endeavour is to find for each element, and, if desired, for each compound, a formula which will express its affinity for all other elements and compounds, so that it may be possible, in his own words, "to discover the law regulating the chemical attraction the elements mutually exert on each other"; and this is achieved, according to him, by "the construction of some geometrical figure which will quantitatively pourtray the chemical properties of the element."

The plan adopted is to arrange the elements into series and columns, as in the usual periodic diagram; the group numbers are plotted along a horizontal ordinate OX, and the series numbers along an ordinate at right angles to the former, OY. There are ten points along OX, filled in the second group by the elements Li, Be, B, C, N, O, F, and Ne, and there are eleven points along the ordinate OY, occupied in the first column by the elements H, Li, Na, K, Ca, Rb, Ag, Cs, ?, ?, and Au. This, it will be seen, gives one of the common forms of the periodic table. Next, for any one element, having one definite valency (one, it may be, of several valencies which it may possess), perpendiculars are erected on the point occupied by each of the known elements, expressing by its height the affinity of that element for each of the others. Thus, choosing the element chlorine, and regarding it as monovalent, vertical lines are to be erected, showing by their length that that erected on, say, the point occupied by cæsium, expresses a high degree of affinity or attraction; the vertical on the point occupied by arsenic, for example, viewed as triad, would show by its shorter length that the affinity of chlorine for arsenic is less than it is for cæsium; a repetition of this process for all known elements produces a number of points, 10×11, or 110 in number, if all spaces are considered, or a smaller number, the number of the actually known elements, in actual practice. Mr. Martin *imagined a curved surface to be drawn through these points,* and proceeds to develop equations which will represent that surface. He shows, so far as the reviewer can see, correctly, that for the complete characteristic equation for the supposed 110 elements, each of which is supposed capable of existing in 8 degrees of valency, there are $2 \cdot 3486 \times 10^{108}$ different possibilities of associating degrees of valency! However, by a device the author mercifully lowers this number to 8448, being 64 times 132; 132 represents the number of constants for the characteristic affinity-surface for each element existing with only one of its possible eight valencies exercised.

We have italicised the words "imagined a curved surface to be drawn through these points" because there lies the crux of Mr. Martin's attempt. What reason has he to join his points? Does he imagine that the interspaces are filled by an infinity of elements of all conceivable atomic weights between the known limits 1 and 240? If not, then the whole system is discontinuous, and the characteristic surface is non-existent.

But we will accept Mr. Martin's method for the moment, and inquire how he imagines affinity to be measured, so as to obtain the lengths of his vertical coordinates. The methods of estimating comparative affinity may be taken as three in number. First, he suggests that while the "energy of combination" should be measured by the heat generated by a reaction starting from the absolute zero, such measurements are impracticable, and, *faute de mieux,* the "heats of formation" at ordinary temperatures must suffice. This method may be better realised by a concrete example. One-third of the heat evolved when boron burns in chlorine amounts to 34·7 calories; one-quarter of that of the formation of silicon chloride is 39·4 calories. These numbers are approximately equal, hence the affinities of boron and of silicon for chlorine are nearly the same. But this is not always the case; for instance, as Mr. Martin points out, $\frac{1}{4}(Si,H_4)=8 \cdot 2$, whereas $\frac{1}{4}(C,H_4)=5 \cdot 2$; yet "undoubtedly of these two bodies, the H is attracted to the C in CH_4 with a greater intensity than it is attracted to the Si in SiH_4." He therefore guards himself by the statement that "it is only when the heat evolved in the formation of a compound is very great that it can be taken as measuring approximately the attractive forces." There may be a little in this, but the reviewer has read something like it before. Second, an estimate of the relative affinity of the elements in two similar compounds may be derived from a consideration of their temperatures of decomposition. Again, that suggestion is at least a century and a half old. Third, temperatures of reaction may be made a rough measure of affinity. For instance, lead oxide is reduced by hydrogen at a lower temperature than iron oxide, hence the affinity of lead for oxygen is less than that of iron. Estimates of such affinities, and their application to the formation of curved surfaces as described, fill 206 pages of the work. Three appendices treat respectively the causes of the absence of other compounds of elements than those which contain the element at a high or at a low grade of valency; the bearing on the phenomenon of life of the critical temperature of decomposition of chemical compounds; and lastly, "the possible significance of alcohol drinking," in which the glorious hope is held out to our remote de-

scendants of a world in which, owing to a decrease in temperature below the freezing point of water, that useful liquid will be replaced by alcohol!

There is a Scots proverb running thus:—"Mickle cry and little 'oo (wool)." The amount of "wool" in this work is surely insufficient for the "cry." Yet there are some suggestive passages, and the author has evidently spent much time over his problem.

A word in conclusion as to the "get-up" of the book. The reviewer, in reading it, felt that he must act as a proof-reader. There is hardly a page on which a misprint does not occur; and such lapses as "The only data available *is* the following:"; the words *uni-* and *tetra*-valent in one line; "to completly (*sic*) picture"; and the printing of almost every sentence as a paragraph, make the reader's task an ungrateful one.

Something, no doubt, may be accomplished in course of time when affinity constants have been numerically determined (and many are already known) to show that they, too, are periodic functions of the atomic weights; but Mr. Martin has not succeeded in pointing out the lines on which this goal is to be reached.

AN ORNITHOLOGIST'S JOURNALS.

Travels of a Naturalist in Northern Europe: Norway, 1871, *Archangel,* 1872, *Petchora,* 1875. By J. A. Harvie-Brown. 2 vols. Pp. xxii+541; with coloured plates and other illustrations and 4 maps. (London: T. Fisher Unwin, 1905.) Price 3*l.* 3*s.* net.

THE journals which compose the greater part of these two handsome volumes relate to three ornithological visits paid to Norway, Archangel, and Petchora about a quarter of a century ago, and the author good-humouredly anticipates their being regarded as "stale news" or "cauld kail het again." On this score, however, there was no need for an apology, for the author tells his story for the first time (apart from previous technical reports), and, besides, the interest of a naturalist's observations depends, not on their date (provided the date be given), but on their intrinsic worth.

As Mr. Harvie-Brown is an accomplished ornithologist, an enthusiastic faunist, and the author of some delightful and valuable books on the natural history of Scotland, it goes without saying that these journals contain some interesting scientific information and some picturesque narrative. But the trouble is that to discover these oases we have to traverse what seem to us dreary deserts of trivial and commonplace monotony, and we can hardly control our impatience by remembering that there had to be many trivial and commonplace days before the author found the nesting-ground of the little stint. What is published is just what was written down at the close of each day, and it follows that items which loomed large at the moment, such as the supper menu, appear of little importance to the callous reader, as doubtless to the journalist himself in retrospect at Dunipace. He got such a gorgeous "bag" of birds—1019 skins and 1021 eggs from the Petchora hunt alone—that we can sympathise with his wish to live his hunting days on the tundra over again; we only wish that his recapitulation had not been so terribly *in extenso*. We are much interested to read how Mr. Seebohm came in one evening, "and with a triumphant thump laid on the table, first a Grey Plover, then a Snow Bunting, and then a Curlew Sandpiper; lastly, and most triumphantly—hurrah!—five Little Stints, long looked for, found at last"; but we cannot get up much enthusiasm over the bulk of the narrative.

The tour in Norway was more or less of a novelty in 1871, and much is related that is now familiar. Much has changed, but more remains the same, and one unchanging feature of which the journal affords abundant illustration is the human appetite.

The Archangel region had been but little worked by ornithologists when Mr. Harvie-Brown and (the late) Mr. E. R. Alston explored there in 1872, and they were richly rewarded. The journal becomes more interesting, though our attention is still distracted by Ernst Craemers's toothache, by the size of the packing-case for the birds, by Alston's loss of his big knife ("one made by Wilkinson, of London"), by the number of bowls of milk drunk, and so forth.

The most adventurous journey was that which Mr. Harvie-Brown and Mr. Seebohm took in 1875 to the region of the Petchora, where they were the first to find the eggs of the little stint in Europe. The author shows his powers in the graphic description of the locality and in his story of the discovery. We quote the description of the nest:—

"Rather untidy, rather rough and uneven round its rim, very shallow, sparingly lined with dry grasses and a little leaf or two, which may have been plucked by the bird as she sat in her nest. Round it, deep, spongy, but not wet, yellow moss, the dark green leaves and empty calices of the Arctic Bramble, a tuft of round-stemmed green sedge with seed; a little further off, the now flowerless plants of the sweet-scented dwarf rhododendron, and bunches and patches of long white grass and plants of a small cotton-grass, and other plants and grasses, of which we shall bring home specimens for identification."

There is a fine plate of stint's eggs, and a careful comparison of the little stint and Temminck's stint. Another beautiful plate contrasts the eggs of grey plover and golden plover.

In the course of the Petchora journal we find some notes on habits which are interesting, *e.g.* those relating to the fact that birds which do not perch, or but rarely perch, in other countries, perch in Petchora. Thus, on one occasion, by patiently following up the "tick tjuck" of the common snipe, Mr. Harvie-Brown had the satisfaction of seeing this wader "perched on the tip-top of one of the gaunt branchless blasted larches, quite 70 feet from the ground." Curlews, gulls, snow-buntings, &c., were also seen perching.

"It is, we think, undoubtedly forced upon them by the great flooding of the country, and what was originally forced upon them has become a favourite habit."

The journal for July 7, 1875, gives an artificial table for distinguishing the downs of ten species of ducks, and that is the kind of minute detail more of which we would gladly have welcomed. It is also to the point to be told of the curious antics of the Arctic (Richardson's) skuas:—

"The birds often alighted within fifteen yards of me, raised the wings over the back—when they did this the white or dusky quills showed like a patch upon the raised wings—shammed lameness and sickness, and stood reeling from side to side as if mortally wounded. If I followed them, they continued to try and lead me off; but if I again approached the nest, they flew boldly towards me, and stooped repeatedly."

There are some vivid pictures of the tundra and its birds, there is an interesting account of the Samoyèdes, and there are some instructive notes on the habits both of birds and men, for all of which one is grateful, wishing only that there had been more of this wheat and less of the journalistic chaff.

PRACTICAL SEA-FISHING.

Practical Sea-Fishing. A Handbook for Sea Anglers. By P. L. Haslope. Pp. 274; illustrated. (London: Upcott Gill, 1905.) Price 3s. 6d.

SEA fishing is not a new form of sport, nor is it a subject which has been neglected by authors. We have several excellent works on it, such as "Sea Fishing" by "John Bickerdyke" in the Badminton Library series, and "Sea Fishing on the English Coasts" by Aflalo, so that a new book requires some justification for its production.

The work under review is perhaps worthy of a place in the sea fisherman's library, but it is, in our opinion, in no way fitter to occupy that position than either of the books already mentioned. It is obviously written by a practical sea-fisherman who has tested most, if not all, of the methods of rod and line fishing which he recommends; but it is as obviously written by a man whose experience has been mostly confined to the south coast, as south coast methods are much more often referred to than those of other parts of the country.

The author does not, however, appear to be so conversant with some of the methods of net-fishing which he discusses as he is with those of rod and line fishing. For instance, he considers the otter-trawl "a much more manageable net" for the amateur than the beam-trawl, a point we think open to doubt. It is true that the otter-trawl is more easily stowed away on board, but we think that its advantage over the beam-trawl for the amateur ends there, especially if the vessel is not a steamer. The difficulty of getting the otter-trawl to spread out and of getting it to fish properly is only known to those who have tried, and we should certainly recommend the amateur to use a beam-trawl, which, it is true, may capsize when being lowered, but otherwise will always fish when down.

When Mr. Haslope touches upon natural history or the habits of sea-fish he is clearly not so much at home as when he is discussing methods of capture. For instance, he refers to the angel fish, *Rhina squatina*, as a species of ray. He mixes up *Atherina presbyter*, the sand-smelt, and *Osmerus eperlanus*, the true smelt, and says "the Atherine, or sand-smelt, is the variety generally met with" (p. 100). In speaking of the sand-eel, he says:—"Any not required for bait should be fried and eaten, as they form a delicious article of food when in roe, but are not so good in winter" (p. 52). In our experience the sand-eel breeds in the winter; but perhaps Mr. Haslope means that after they have spawned they are not so good. He says of the grey mullet that "they feed chiefly on some kinds of sea-weed and decaying vegetable matter" (p. 95). It is true that algæ are occasionally, and perhaps often, found in the stomachs of grey mullet, but we should put down the staple food of the species as being animal. If we recollect rightly, in the aquarium at the Plymouth laboratory these fish are fed chiefly upon nereid worms. Day says that they are very destructive to molluscs and minute Crustacea, and that they also eat larvæ and ova ("Brit. Fishes," I., p. 234).

The English of the book is not all that can be desired, and badly arranged sentences are far too common. For instance, "In form this fish is very slender and its shape has some resemblance to that of a large sand-eel, which enables it to pursue its prey with great rapidity" (p. 50). "Great quantities of these crabs are taken in trammels and the shell on the back is so sharp and rough that it quickly cuts the twine, sometimes damaging the nets almost beyond repair. They are generally thrown away or used as manure for the gardens" (p. 60).

The directions as to skinning a ray are exceedingly involved:—

"To skin a Ray, remove a small portion with a sharp knife and grasp it with an old cloth in the left hand. This affords a firm hold, and by its means the whole skin can be readily stripped off. Meanwhile hold the fish firmly with the right hand, making with a knife a hole, or an incision, to enable the fingers to obtain a firm grip. Leave it upon the board in the open air with the flesh side upwards, and when dry it will have attained the consistency of horn, &c. . . ." (p. 68).

We prefer the old books on the subject of sea fishing, although, as we have said, the practical advice in the present work is thoroughly sound.

FRANK BALFOUR BROWNE.

MATTER AND FORCE.

(1) *Molecular Forces and Newtonian Laws.* By Alex. Clark. Pp. 237; illustrated. (Glasgow: W. and R. Holmes, 1905.) Price 3s. 6d. net.

(2) *Explication méchanique de la Matière, de l'Électricité et du Magnétisme.* By M. Despaux. Pp. 210. (Paris: Félix Alcan, 1905.)

(1) "BY deductions from the Newtonian Laws of Force and Motion the Author accounts for all the facts of Magnetism, Electricity and Chemical Affinity and proves their identity with gravitation" (extract from circular of publisher). We ourselves do not think that the author is successful in his attempt;

but this opinion of ours may possibly arise from the difficulty we have felt in fathoming his arguments. There is an originality of statement about them which often makes it impossible to decide hurriedly as to whether they are right or wrong. For example:—

"Electricity is not to be confounded with the electric spark—they are the direct opposites of each other. Electricity is a force of attraction which brings particles of matter into contact; the electric spark is the kinetic energy produced by the action of the electric force through the available distance, and has a dispellant effect upon the particles. By the conservation of energy the electric force ceases to act when the spark is produced. The potential is then converted into kinetic energy. This affords a conclusive reply to the theory, adopted by some eminent authorities, that electricity and light are identical. Light is a form of heat and has always a dispellant effect upon the particles of matter. It is therefore the direct opposite of electricity, which is a force of attraction."

This is certainly not all wrong. The question is how much of it is right? To those readers who are attracted by the above extract we recommend the two hundred and thirty-seven pages of this volume.

(2) Just as in the work reviewed above the dependence of forces upon position is made the universal law, so here the essential identity of all forces is sought for in a kinetic view of matter.

All phenomena of attraction are explained, and can be reproduced by the simple rotation of a screw or turbine in water and in air. The turbine is presented as the universal motor which gives rise to molecular attractive forces and the phenomena which accompany them. The author claims to assume nothing besides the propulsive motions produced by rotations of molecular turbines, and congratulates himself on the rare good fortune that everyone can understand the effects of such rotation.

A number of experiments with ventilating fans are described; the author then wanders off into a comparison of a magnet with a living being, and a consideration of the position of man in the universe.

It is a commonplace to suppose that scepticism is the beginning of belief; the author's creed is accompanied by the usual doubt as to the validity of many of the conclusions of modern science. The value of his criticisms can be measured by his objections to the recognition of the essential identity of light and Hertzian waves. He disposes of the argument which rests on the identity of velocity of the two phenomena by saying that all waves produced in the ether, of whatever nature they may be, must, in fact, have the same velocity, since the velocity of a wave depends, not on its form, but only on the elasticity and density of the medium of transmission, which in this case is the ether.

We cannot look upon this book as a serious contribution to scientific literature, but we readily admit that there are analogies between the effects of the motions which the author describes and other physical phenomena; and if these were systematically described a very interesting volume could be made. But there is so much here that is merely fanciful that we must advise anyone who reads it to read it with caution.

OUR BOOK SHELF.

A Descriptive Handbook of Architecture. By Martin A. Buckmaster. Pp. xvi+188. (London: George Routledge and Sons, Ltd., n.d.) Price 3s. 6d. net.

This is a little book which is intended to help those to whom architecture is a subject of ever-increasing interest. The author refers to a subject which Mr. Banister Fletcher has already brought forward prominently in the preface to "The History of Architecture" and in a paper read before the University Extension Guild, namely, the inclusion of the study of historical architecture in a liberal education. It certainly seems that, owing to the ease of travel, the use of photography and other causes, a knowledge of the elementary principles and forms of the various types of architecture might well be expounded to the senior forms of educational institutions, and this way of interesting the rising generation in matters which appertain to everyday life and observation would tend largely to increase interest in matters artistic and practical.

Concerning the book under notice, much cannot be expected for the low price at which it is published, and it would probably have been better had the author dealt with one period of architecture, and have done that thoroughly, rather than have taken up so large a field. It has resulted in an essay which is "scrappy," and from which we are afraid the attentive student will gather very little of much use to him.

One or two points call for revision. Why is "mediæval" architecture made to *end* at 1090 when most people hold that it *commences* about that time?

Plate iii*a*. is merely an enlargement of part of plate xviii., and might be omitted. Some of the illustrations are very poor; that on p. 20 would lead the student to believe that the Temple of Theseus and the Parthenon had suffered from an earthquake since we saw them last spring!

The ground range of the columns to the Colosseum is not Doric, dentils are wrongly spelt on pp. 25 and 27, and the Temple of Zeus, Athens, is given another name on p. 28. The giving of exact dates for each period, and the printing at the top of each page, are sure to mislead the student; for no style can be truly confined within a period of such exactitude as, say, 1377–1547, and the student should be warned against such an attempt.

The line illustrations are of an amateurish description, and plates viii. and xi. should be re-drawn.

Plate xliv. seems to be a copy of a plate in a well known history, though this is not acknowledged. The division of early Christian architecture into Roman and Byzantine is likely to confuse the student, as Roman is always considered historically as pagan architecture.

Proceedings of the London Mathematical Society. Vol. ii. Pp. xx+490. (London: Francis Hodgson, 1905.)

The present volume of *Proceedings*, though the size of the page has been changed, and larger type is used, contains about the same amount of subject-matter as its predecessors. It affords evidence that the publication of researches in higher mathematics still receives the same care and attention which it has for many years past obtained at the hands of the small body of workers who mostly travel up on Thursdays by the 2.15 train from Cambridge to attend the meetings in Albemarle Street with their friends. It contains interesting obituary notices of Mr. Ronald Hudson and Dr. Pirie. Among the contributors we

note the well known names of Dixon, Glaisher, Hilton, Hobson, Jackson, Lamb, Love, MacMahon, Morley, Volterra, Rayleigh, Young, and many other mathematicians. An attempt to classify the papers by subject-matter would be difficult, but a general survey of the ground covered suggests that a not inconsiderable proportion, possibly as much as a half, of the work done comes under the heading of "analysis."

But while the reputation of English mathematical research is thus being maintained, it does seem a pity that there is no society which has undertaken the task of popularising the higher study of mathematics in our country in the way that has been undoubtedly done on the other side of the water by the American Mathematical Society, with its *Bulletin* containing full reports of meetings of mathematical societies, educational appointments, and courses of university lectures. The Mathematical Association has done much to render elementary mathematics more practical and interesting. The duty of impressing on the proper authorities the need of providing more fully for instruction in *advanced* mathematics in our *technical* colleges has not as yet been undertaken by any body of mathematicians, yet the matter is an urgent one as affecting national progress in the face of foreign competition. In connection with most of the papers before us, an enormous amount of work is generally done in refereeing previous to publication. Is it not possible that the energy thus expended might with advantage be diverted into some such directions as those above indicated?

Catalogue of the Collection of Birds' Eggs in the British Museum (Natural History). Vol. iv., Carinatæ (Passeriformes, continued). By E. W. Oates, assisted by Captain S. G. Reid. Pp. xviii + 350; 14 plates. (London, 1905.)

IN this volume the authors record the eggs of seventeen families of passerine birds contained in the national collection, thus carrying down the work to the family Certhiidæ (creepers), so that another volume ought, apparently, to bring their task to a conclusion. The total number of species catalogued in the volume before us is 620, which are represented by no less than 14,917 eggs—figures which give some idea of the heavy work the authors had to undertake. Fortunately, the Radcliffe Saunders and the C. B. Rickett collections were received in time to allow their quota to be added to the MS.

We had hoped that as the work progressed the authors would have seen their way to modify the style of the paragraphs recording the distinctive features of the various species catalogued. We regret to see that this is not so, and with the same dreary and wearisome iteration we find entry after entry commencing with the statement that the eggs of such-and-such a bird are of such-and-such form and colour. As a matter of fact, if the English names of the various species had been printed in the same lines as their scientific titles there would have been no occasion to mention the word "eggs" at all in the descriptive paragraphs, which should commence merely with a reference to their form and colouring. By this means not only would much valuable space have been saved (as might also be done in the mode of making the entries themselves), but the reader would have been spared that everlasting and utterly superfluous repetition which is so irritating to any person of literary tastes. We may also direct attention to the crude and schoolboy-like style of composition characterising almost the whole of the paragraphs in question. Reference may likewise be made to some imperfection in the method of recording localities. If, for instance, it is necessary to tell us on p. 16 that certain places are in the Nilgiri Hills, it was surely incumbent on the authors to give the same piece of information on p. 8, while to wait until p. 264 before stating that the Nilgiri Hills themselves are in southern India is a very remarkable proceeding. We are also surprised to learn (p. 162) that Dharmsala is in Kashmir.

The great feature of the volume is the beauty of the fourteen coloured plates of eggs, each containing a large number of figures, all of which have been drawn and coloured by Mr. H. Grönvold. These serve to illustrate very graphically the degree of constancy or variation which obtains in the egg-characters of the different family groups, and in addition to this show some very remarkable examples of individual variation or "sports."

Leather for Libraries. By E. Wyndham Hulme, J. Gordon Parker, A. Seymour-Jones, Cyril Davenport, and F. J. Williamson. Pp. 57. (London: Published for the Sound Leather Committee of the Library Association by the Library Supply Co., 1905.) Price 1s. 6d.

THIS interesting book, which may have a considerable influence on the improvement of book-binding, consists of five chapters, one by each of the authors whose names are on the title-page, three of whom are members of the Sound Leather Committee of the Library Association, and may therefore be considered as authorities on the subjects of which they write.

When light leather is tanned by bark and many other vegetable tanning substances the skin becomes coloured, and this colour cannot be removed without deterioration of the leather. In 1565 sumach tanning was introduced into England; this process leaves the skin white and in a suitable condition to receive the necessary dye. Experiments conducted by the Society of Arts Committee have shown that sumach tanning is the most suitable for binding leathers. Unfortunately this process is a slow one, and other tanning materials which act more rapidly have been employed; some of these, however, have a deleterious action on the leather, causing it to decay rapidly. Another cause of the short life of some modern leathers is the use of sulphuric acid at one stage of the process. This acid combines with the fibre and cannot be removed; it has a corrosive action on the organic matter, which action has often been attributed to the presence of sulphur in the coal gas used for lighting. In some libraries, however, which are not lighted by gas, the bindings have been found to perish in the course of a few years, and the presence of sulphuric acid in these leathers indicates the cause. Sulphuric acid is also used in connection with the aniline dyes frequently employed for colouring. Another source of weakness is the splitting of the leather in order to obtain smooth surfaces; this process necessarily cuts the network of fibres, and thus diminishes the strength of the material. The tanner should have regard to the sources of the skins, and if they are imported it is advisable to consider the treatment that they have undergone before coming into his hands.

It is impossible to do justice to this book in a short notice, but the attention that has recently been directed to the subject seems already to have borne fruit, for in the advertisements of leather-sellers and bookbinders at the end of the book there are such notices as "dressed according to the recommendations of the Society of Arts Report" and "guaranteed free from mineral acids." H. M.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

British Mosses.

In the review of Dr. Braithwaite's "British Mosses" which appeared in your number of August 31 (vol. lxxii. p. 425), I attributed the finding of *Catharinea tenella* to Lord Justice Stirling, and I did so on the authority of a passage relative to the plant in Dr. Braithwaite's supplement. The Lord Justice is, I find, desirous that it should be known that the entire merit of the discovery is due to Mr. E. S. Salmon. "I had the good fortune," says the learned judge, "to be his companion when the little plants were gathered, but his eye detected them in the field, and by his acuteness the true name of them was discovered." I am glad to second the Lord Justice in his desire that no mistake should be made in this matter, and I beg your courtesy to insert this short note. E. F.

November 8.

Border occasionally seen between Light and Dark Regions on Photographic Prints.

Since my recent brief note on a photographic appearance, Mr. Burke has informed me that the subject attracted the attention of Sir George Stokes, and was thought worthy of a communication from him to the Royal Society in May, 1882 (*Proc. Roy. Soc.*, vol. xxxiv. p. 63).

Had I been aware of that I should, of course, have referred to it. It seems to me now that there may be more than one explanation of such an appearance.

OLIVER LODGE.

Halation.

When a photograph is taken of a dark object with a bright object or the sky some distance behind it, blurring occurs where the images of the objects meet.

That part of the bright object from which only a part of the lens is visible (the rest of the lens being cut off by the dark object) forms an image of varying brightness in the shape of a band which covers the edge between the images of the dark and light objects. If the bright object be at an infinite distance from the lens, the breadth of the band will bear approximately the same ratio to the diameter of the lens as that which the focal length of the lens bears to the distance of the lens from the near object.

It seems probable that many cases of halation are due to this cause. J. A. COBB.

108 Church Road, Richmond, Surrey, November 13.

The Engineer's Unit of Force.

I am much indebted to "The Reviewer" for his courteous answer to my letter on the subject of the engineer's unit of force in your issue of November 2.

I readily admit that the engineer's unit of force may be so defined as to make it a constant quantity independent of locality; but does the engineer *in actual work-a-day practice* make use of this invariable unit? In problems involving the derived unit of work, does he not, as a matter of fact, estimate the work done or the potential energy, as the case may be, by multiplying together the distance factor and the weight (*i.e.* the force) factor *without making any allowance for the variation of the latter with latitude?*

The question at issue, it seems to me, narrows itself down to this: is the title "engineer's unit of force" to be applied to the variable unit in actual use by the engineer, or is it to be restricted to the absolute gravitational unit, which may be defined, but which in nine cases out of ten is not actually applied in engineering practice? D. J. CARNEGIE.

Newton Abbot, November 6.

It is quite true that in engineering practice a correction for latitude is seldom made in regard to the gravitational energy of a raised weight, the reason being that other and very much larger sources of error are usually present. But under sufficiently refined conditions this small correction is actually made. A Bourdon pressure gauge registers pounds per square inch in absolute measure the same everywhere. If Mr. Carnegie considers the pound force to vary with locality, what is his value, in foot pounds, for Joule's equivalent at the centre of the earth?

But surely even Mr. Carnegie himself must use the foot-pound unit, and hence the pound-force unit, in an absolute sense, when applied to such quantities as the kinetic energy of a rotating fly-wheel, the strain energy of a stretched spring, the work done on the piston of a steam or gas engine, the energy of motion or of position of a planetary body, &c.

The present case is an illustration of the apparent inability of academic writers to understand the engineer's position in this matter, and of the confusion which inevitably arises from the combination of two closely related systems of units. In any dynamical system the magnitude of unit mass is quite arbitrary, and the pound mass possesses no intrinsic merits over any other unit. Indeed, the choice of the pound unit has proved to be a most unfortunate one, for the conception of inertia or mass, coming as it does after that of force, finds the pound force already established and ingrained in the mind, forming an effective barrier against the practical adoption of the derived poundal, and being a fruitful source of error on account of the new and old meanings attached to the word pound. People do not, and never will, think in poundals, and so custom has compelled its advocates to incorporate into their system the pound force and the foot-pound unit of work, a tacit admission of its practical failure. Engineers contend that this duplex system with its overlapping terms is harmful and quite unnecessary. They advocate a single system which, so far as possible, shall adopt units in common use. The system used by them fulfils all requirements. It is an absolute dynamical system. Its terminology is not divorced from common thought and speech. It gives an exact and absolute meaning to the pound force and consequently to the foot-pound unit of work, and its unit of inertia has a distinct name of its own, never used in the sense of force, thus avoiding the conflicting nomenclature of the present mixed system. The engineer's and the C.G.S. systems are sufficient for all purposes, and it would be a great gain if the academic British system could be abandoned. THE REVIEWER.

THE EXPLORATION OF THE ATMOSPHERE OVER THE TROPICAL OCEANS.

THE study of the trade-wind region by the use of kites was first proposed by Mr. A. L. Rotch at the meeting of the British Association at Glasgow in 1901, after he and his assistant, Mr. Sweetland, had obtained a series of observations with them during a voyage across the North Atlantic. This method of investigation was later adopted by other meteorologists, notably by the French Scandinavian expedition to explore the atmosphere, which, under the direction of M. L. Teisserenc de Bort, flew kites in 1902 on the Baltic, and last year by Prof. Hergesell, who communicated to the Aëronautical Conference at St. Petersburg the interesting results of a cruise on the yacht of H.S.H. the Prince of Monaco in the vicinity of the Azores and Canaries. During this voyage fourteen kite-flights, some of which reached a great height, were made, and in a communication to the French Academy of Sciences on January 30 Prof. Hergesell said:—"Un courant de S.W., qui correspondrait au contre-alizé théorique, n'a jamais été trouvé par les cerfs-volants bien qu'ils aient plusieurs fois dépassé la hauteur du Pic de Ténériffe. Plusieurs constatations m'amènent à penser que les vents de S.W. observés au Pic par plusieurs observateurs sont d'origine locale et dûs à l'influence de l'île."

Thus Prof Hergesell believes that the north-west wind which was found overlying the thin north-east stratum is a return current, or anti-trade, for he says:—"Der Luftersatz im Anti-passat erfolgte deshalb vorwiegend in der von uns durchforschten Gegend aus nordwestlichen Richtungen" (Aëronautical Conference, St. Petersburg, 1904, supplement vii., p. 91).

It appeared to the writers that these conclusions, which tended to invalidate the existence of the upper anti-trade, required further investigations, and by mutual consent we decided to have these carried on by two of our assistants, Mr. Clayton, meteorologist at Blue Hill, and M. Maurice, assistant at Trappes, aboard the *Otaria*, a large fish-carrying steamer, equipped with the electric kite-reel which M. Teisserenc de Bort had used for kite-flying at sea.

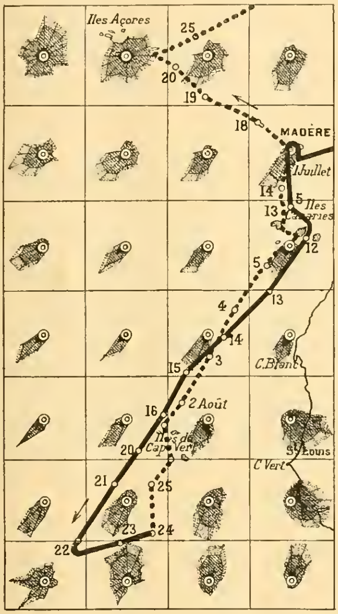

FIG. 1.—The route of the *Otaria*. The diagrams in centre of squares show the mean direction of surface winds in summer, by Captain L. Brault.

A study of the high barometric pressures at the Observatory of Trappes (see *Comptes rendus*, 1899) led to the conclusion that there exists, generally, at a moderate altitude, a zone of light winds which ordinarily the kites cannot penetrate. While it is true that at sea an artificial breeze may be created by steaming in a direction contrary to that of the wind, this method is inefficient in the trades, because, if, as is usually assumed, there is almost complete reversal in the directions of the upper and lower winds, the top kite arrives in the south-west current while the others are still in the north-east wind, and consequently the flight is stopped just where the change of regime commences. Therefore it is necessary to employ a single kite and a boat which is sufficiently fast to lift the kite regardless of the direction of the wind, but as these conditions cannot always be realised, in order to attain great heights on this expedition the paper pilot-balloons already tried at Trappes were used. Since these balloons were only intended to show the direction of the wind, they did not usually carry instruments, and their drift and height were determined by simultaneous angular measurements at the ends of a base-line on the shore, with the exception of one balloon which was observed from the boat. These soundings of the atmosphere, executed at various places, notably at Madeira, Teneriffe and Cape Verde Islands, and also over the open sea, gave the following results, to which are added observations of winds on two tropical mountains and during one of the kite-flights.

In the table on p. 56 the first column indicates the upper limit of the north-east trade, and the second column the limit of the associated north-west wind, these heights being expressed in metres. In the third column the figures in parenthesis show the maximum

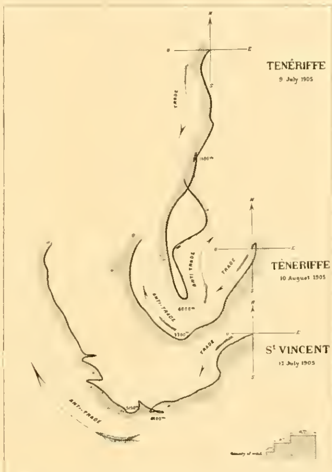

FIG. 2.—Direction of wind at great height, shown by the tracks of balloons.

heights at which the balloons were observed moving in the anti-trade, from south-east, south, or southwest.

There follow observations at different heights on the peaks of Teneriffe and Fogo, the figures after the direction of the wind being its velocity in metres per second. There is also noted the drift of the clouds passing above the peaks. The diagrams (Fig. 2) represent the direction and speed of the balloons which were sent up from Teneriffe on July 9 and from St. Vincent on July 17.

The tables and figures show that the winds blowing toward the equator have a direction varying between N.E. and N.W., these last being usually above the N.E. stratum, the thickness of this layer of the *trades* in the vicinity of Teneriffe being about 3000 metres or 5000 metres. Above it blow S.E., S., and S.W. currents which form the *anti-trades*, its thickness being probably very great, though its density is small. Thus, as was deduced from the observations of clouds and volcanic dust, the east wind in the vicinity of the thermal equator extends very high. At the Cape Verde Islands the south-east

wind was observed by a balloon up to a height of 11 kilometres.

As is seen, these results confirm the accepted theory of the *trades* and upper *anti-trade* in those parts of the Atlantic explored by the *Otaria* (see chart of route, Fig. 1), and prove that, contrary to the opinion of Prof. Hergesell, there exists a return current, or anti-trade, with a well defined southerly component.

We hope to give in a subsequent article the conclusions regarding temperature and humidity derived from the kite-flights made on the *Otaria*.

Winds above the Atlantic, between latitudes 11° and 37° N., longitudes 15° and 26° W., observed during the cruise of the S.Y. "Otaria" in 1905.

SOUTH AFRICAN ZOOLOGY AND PALÆONTOLOGY.

THE recent visit of the British Association to South Africa affords a favourable opportunity of directing attention to the zoological and palæontological work now being carried on by the museum at Cape Town under the able direction of Mr. W. L. Sclater, more especially as exemplified in that excellent serial publication entitled the "Annals of the South African Museum." Of this serial, which commenced in 1898, three volumes have been completed, and some seven parts of the fourth volume published up to the end of July of the current year, making a total of at least twenty-nine separate parts, each devoted to a special subject.

From the time that he took charge of the museum, Mr. Sclater appears, indeed, to have determined to devote all his energies towards increasing our knowledge of the fauna of South Africa. His mode of accomplishing this praiseworthy object seems to be threefold. In the first place, efforts have been made to increase the collections in the museum at Cape Town—both as regards the exhibition and the study series—by all possible means, and thus to afford as ample a basis as possible for the work of specialists, and at the same time to awaken increased interest on the part of the public in the museum itself. The second part of the programme consists in the publication of monographs of such portions of the South African fauna as are ripe for this mode of treatment. As examples of work of this nature may be cited the handsome volumes on the mammals and birds of the country, published some few years since, and duly noticed in our columns as they appeared.

Work of the above nature consists to a great extent in collating, revising, and adding to the labours of earlier naturalists; but, in addition to this, much of an altogether newer type has to be made known to the scientific world in such a rich, and in many respects little-worked, field as that presented by South Africa. And it is to work of this latter description that the "Annals of the South African Museum" are mainly devoted. Fortunately, the officers of the Geological Survey of Cape Colony have availed themselves of this excellent means of publishing the results of researches into the palæontology (both zoological and botanical) of this part of South Africa, and the "Annals" accordingly promise to afford within a few years a perfect mine of information with regard to South African zoology and palæontology.

Although the description of more or less entirely new work occupies much of the "Annals," monographs of groups, or revised lists of groups already monographed, come within its purview. For example, the moths of South Africa, which for many reasons could not probably be monographed in separate volumes, are in course of description by Sir George Hampson, of the British Museum, and two parts of his monograph have already appeared. Again, Mr. Sclater has taken advantage of this mode of publication to issue a revised list of South African birds, containing such additions and corrections as have been made since the issue of the volumes on this group in the series devoted to separate monographs of the South African fauna.

To mention by name all the papers included in the volumes of the "Annals" already published would be altogether beyond the limits of available space, and it must suffice, therefore, to refer to a few others. In the palæontological series, the first part of the important account of the fossil floras of the Cape, by Mr. A. C. Seward, of Cambridge, has already received special notice in NATURE. The molluscs and brachiopods of the Bokkeveld beds respectively form the subjects of two papers by Mr. F. R. C. Reed; and these and the trilobites, which are described in another paper by Mr. P. Lake, serve to demonstrate the Devonian age of the beds in question, and thus point to a definite period when at least a part of what is now South Africa was beneath the sea. The affinity of the trilobites to South American types is noteworthy. A fifth paper, by Mr. F. Chapman, is devoted to the foraminifera and ostracods from shallow water deposits of Lower Cretaceous age in East Pondoland. In the zoological series, in addition to those already mentioned, six papers by Mr. Peringuey, assistant director of the museum, form an important contribution to our knowledge of South African beetles; while in another part the Rev. O. Pickard-Cambridge has described a number of new spiders, including three new generic types; and there are many other papers of equal importance and interest.

In conclusion, we congratulate all those who have done so much good which this serial has been the means of communicating to the world, and trust that financial considerations will not be allowed to interfere with the continuation of such a valuable and important publication.

R. L.

SCIENTIFIC RESEARCH IN THE PHILIPPINE ISLANDS.

THE valuable scientific work which is being carried out in the Government laboratories, Manila, has from time to time been noticed in these columns, and the record for the third year is stimulating reading and reflects the greatest credit on those by whom it has been done, and on the enlightened Government which has rendered it possible.

Dr. Paul Freer details in his report [1] the routine work of the laboratories and the nature of the investigations which have been carried out. In the chemical laboratory the analysis of foods and drugs, the standardisation of weights and measures, and the examination of the natural products of the country, vegetable and mineral, are some of the subjects dealt with. In the biological laboratory clinical investigations and pathological examinations are carried out, while valuable work is being done by the attached botanist and entomologist. The serum laboratory has been occupied in the preparation of an anti-rinderpest serum, which greatly mitigates the ravages of the disease, and of vaccine virus, while investigations have been made on plague and on the preparation of a cholera vaccine.

FIG. 1.—The New Laboratory Buildings, Manila.

While so much good work has been done in the past, we may expect considerable development in the future, as Dr. Freer is able to chronicle [2] the erection of new laboratories, the completeness of the arrangement and equipment of which will materially facilitate scientific investigation. The accompanying illustration shows the front elevation of the new buildings, which have the form of the letter "T," consist of two stories, and are erected on a site 23 acres in extent, on which an up-to-date hospital is also to be established, laboratory and clinical work thus being brought into proper contiguity.

The eastern half of the structure is devoted to biological work, and comprises rooms for the preparation of culture media, bacteriological and pathological laboratories and pathological museum, botanical room and herbarium, entomological room, and general biological laboratory, while the western half is devoted to chemical and physical work, and comprises laboratories for organic and physiological chemistry, a commercial laboratory with stills, baths, and machinery for carrying on commercial processes on a laboratory scale, rooms for photometry, adjustment of weights and measures, assaying and mineral analysis, organic combustions, agricultural work, food analysis, &c., together with balance rooms, laboratory for physical chemistry and physics, and a room for spectroscopes and instruments of precision. All the work tables are supplied with gas, electricity for light and power, steam, vacuum, and compressed air. There are in addition boiler and engine house, cold storage, cremating furnace, photographic laboratory, incubating chambers, animal house, serum laboratory, &c.; nothing, in fact, seems to have been forgotten.

Lastly, there is an excellent library of some 17,000 volumes, and the list of current periodicals on all subjects is very complete. Reference is made to the difficulties which have had to be overcome in preserving the books from the ravages of damp and of insects in this tropical climate. The legs of the book presses (which are of metal) stand in tins of petroleum, which effectually prevents the access of insects when the books are on the shelves, and varnishing the books with the following varnish has been found to be of service:—pure white shellac 50 grams, resin 20 grams, bichloride of mercury 1 gram, alcohol 1000 c.c. The constituents are mixed, and after twenty-four hours are filtered. The report and bulletin are illustrated with a number of plates, plans, and charts.

R. T. HEWLETT.

DR. WALTER F. WISLICENUS.

ASTRONOMERS have universally acknowledged the value, the accuracy, and the completeness of the "Astronomische Jahresbericht," which, appearing annually for the last six years, has presented an admirable history of the progress of the science. The systematic arrangement and organisation of its contents have made this compilation a necessity in every observatory, and the announcement of the death of its originator, Dr. Walter Wislicenus, at the early age of forty-six will have been received with profound regret by all who know this work. The deceased astronomer, who occupied the position of Professor extraordinary at Strassburg, began his career at Dresden, but the fame of Winnecke as a teacher, coupled with the advantages afforded by the efficient equipment of the new observatory at Strassburg, induced Dr. Wislicenus to migrate to that university, with which he remained connected until his early death.

Although Dr. Wislicenus will be best remembered for his literary work, and particularly for that already mentioned, his services to practical astronomy were by no means few or unimportant. In 1882, while still a student at Strassburg, he took part in the German expedition to Bahia Blanca to observe the transit of Venus, and for this task he was eminently fitted by the study he had made of the use of the heliometer. He not only continued to observe with this instrument after his return to Strassburg, but added a series of meridional observations of the zone -2° to -6°, and some of the results of his work are incorporated into two papers, one on the determination of the period of rotation of Mars, and the other on the absolute personal error in meridian observations; but his most important services were rendered in the cause of astronomical literature.

Besides his articles in Valentiner's "Handwörter-

buch der Astronomie" on stellar photometry, spectroscopy, and chronology, he published a treatise on the determination of geographical positions for the use of travellers and explorers which was favourably received. His periodical compilation on the current history of astronomy has proved itself so useful and important that it is to be hoped it will be continued by some other hand. As a teacher of astronomy he is acknowledged to have been very successful. His presentation of the most recondite subjects was masterly and edifying, arresting and retaining the attention of his class.

NOTES.

THE list of honours conferred by the King on the occasion of His Majesty's birthday, November 9, includes the name of Prof. G. H. Darwin, F.R.S., who has been appointed a Knight Commander of the Order of the Bath (K.C.B.). Dr. W. Saunders, director of the experimental farms of the Canadian Department of Agriculture, and Dr. M. A. Ruffer, president of the Egyptian Sanitary Board, have been made Companions of the Order of St. Michael and St. George (C.M.G.). Sir Felix Semon has been appointed Knight Commander of the Royal Victorian Order, and the honour of knighthood has been conferred on Mr. Arthur Chance, president of the Royal College of Surgeons in Ireland, and Prof. McFadyean, principal of the Royal Veterinary College, Camden Town.

THE death of Prof. Albert von Kölliker on November 2, at eighty-eight years of age, has deprived the scientific world of one of the founders of modern systematic histology, and the eldest of the illustrious teachers and investigators in the realms of embryology and comparative anatomy. An outline of his scientific work was given in NATURE of May 5, 1898 (vol. lviii. p. 1), as a contribution to our series of Scientific Worthies; but his memoirs and other writings are so numerous that no adequate description of them can be contained within the limits of a short article. In the course of that appreciative notice, it was pointed out that von Kölliker was one of the first to realise that the complete justification of the cell-theory must be accomplished by a study of the whole history of animal tissues, from the fertilised egg onwards; and his papers on the development of Cephalopods (1844) and of Amphibia (1846–7) represent the first results of this conviction. Von Kölliker went to Würzburg in 1847 as professor of human anatomy, and almost immediately joined von Siebold in founding the *Zeitschrift für wissenschaftliche Zoologie*, to the early numbers of which he contributed a series of important papers. In the article already referred to mention was made of the considerable series of embryological and other papers, and of the masterly text-books, of which he was the author. In 1896, as a recognition of his brilliant scientific services, he was nominated a Knight of the order *pour le mérite*. He was elected a foreign member of the Royal Society in 1860, and received the Copley medal of the society.

DR. CHARLES WALDSTEIN has been created by the King of Denmark a Knight of the Royal Danish Order the Danebrog.

THE *Athenaeum* announces the death, in his seventy-fifth year, of Dr. Johann Meidinger, professor of physics at the Technical Institute in Karlsruhe, and author of a number of works dealing with the practical side of his subject.

THE superintendent of Commercial Agencies in Canada has expressed his conviction, says the *Journal of the Society of Arts*, that the establishment of a service of commercial agents to reside in British possessions for the purpose of reporting to the Commercial Intelligence Branch of the Board of Trade in London would be of immense benefit to the Empire at large. Such agents should report on all matters concerning the resources, growth, local enterprises, public contracts, openings for trade, and the investments for capital, as is done by His Majesty's consular officers and commercial *attachés* in regard to foreign countries. The superintendent adds that there is not in the whole of Canada a British official who can answer questions of the British exporter concerning Canada, while the Americans "have in the neighbourhood 190 officials."

AT a meeting of the Incorporated Society of Medical Officers of Health on November 10, Dr. Christopher Childs read a paper on a comparative study of the Lincoln, Maidstone, and Worthing epidemics of typhoid fever. After discussing the features presented by these epidemics, Dr. Childs advocated the retention of a staff of experts specially to investigate, at the earliest opportunity, similar outbreaks in the future, such a staff to consist of specially trained medical officers, bacteriologist, chemist, and sanitary inspectors, and organised by an epidemiologist of repute. Moreover, Dr. Childs advocated that in cases where water authorities refuse to listen to the repeated warnings of the medical officer of health with regard to the dangerous character of a water supply, the Local Government Board should take action to cause those authorities to take the best practicable means for removing the dangers to which attention has been directed.

AT the opening meeting of the new session of the Institution of Civil Engineers on November 9, the new president, Mr. John Gavey, C.B., gave an address in which he reviewed the progress of the telegraph and telephone industries during recent years. As illustrating the growth of telegraph and telephone accommodation provided by the Post Office, Mr. Gavey remarked that the telegraph wire mileage increased from 114,242 at March 31, 1880, to 338,120 at March 31, 1905. The telephone wire mileage rose during the same period from 40 to 253,521. There appears to be little prospect of serious competition between telephony and telegraphy after a certain critical distance has been reached. The determination of the distance over which telephonic speech is possible on various types of telephone circuit is a question of the greatest theoretical and practical interest. Telephone administrations have carefully considered what are the extreme limits of effective commercial speech, taking all the facts into consideration, and allowing a large margin of safety, and it is generally considered that from 42 to 46 miles of the English standard cable is the effective commercial limit. As to wireless telegraphy, the opinion was expressed that it is not likely to supplant, or even to compete seriously with, inland methods of communication; nor does it appear probable that it will, at least in the near future, actively compete with highly developed cable communication, although it may supplement that service. In submarine cable work the same progress may be noted as in other branches of telegraphy, the mileage of cable having increased from 87 nautical miles in 1852 to 212,894 miles in 1902, while it is still increasing. The problem of devising submarine cables for long-distance telephones has yet to be solved.

AN official guide to the Victoria Falls, compiled by Mr. F. W. Sykes, the conservator, has been published by the Argus Publishing Co., Ltd., of Bulawayo, at 1s. The guide has been compiled for the use of visitors, and is interesting throughout. On November 17, 1855, that is,

exactly fifty years ago, the falls were discovered by Livingstone. The native (Sekololo) name for the falls is "Mosi-oa-tunya," meaning "the smoke which sounds." Viewed from any of the surrounding hills, the rising columns of spray, more particularly on a dull day, bear an extraordinary resemblance to the smoke of a distant veldt fire. At sunrise, during the rainy season, a dense white column mounts upwards to a height of 1000 feet, which is visible at a distance of fifty miles from the falls. After a clear description of the places of interest in the neighbourhood of the falls, the book provides geological notes written by Mr. G. W. Lamplugh, F.R.S., botanical notes by Mr. C. E. F. Allen, ornithological notes by Mr. W. L. Sclater, and hints and cautions to visitors.

Two letters from Captain Amundsen, of the Norwegian vessel *Gjöa,* giving the earliest results of his expedition to the north magnetic pole, are published in Tuesday's *Times* (November 14). Captain Amundsen sailed in May, 1903, for Godhavn, on Disko Island, off the coast of Greenland. In the course of his first letter, dated November 24, 1904, he remarks:—February turned out the coldest month, with an average temperature of $-40°\cdot5$ C. Commenced on March 1, 1904, putting down the stores for the coming spring voyage to the vicinity of the pole. Observed during this tour—in the interior of the country—our lowest temperature, $-61°\cdot7$ C. Came back at the end of May. The summer I have spent in magnetic observations around the station. Wiik has put up the variation instruments—October, 1903—and has attended to them the whole time. Ristvedt is the meteorologist. Lieut. Hansen has to take care of the astronomical observations. Lund and Hansen have their hands full on board. The variation instruments will be kept in function until June 1, 1905. Besides the variation instruments, which have been in continual function, we also have made daily absolute observations. Along with the meteorological observations, we have also made observations of the aurora borealis. Besides we have ample collections of ornithological, ethnographical, and botanical matter, and some fossils. It is my intention to make my way out of the ice and go direct to San Francisco in the autumn of 1905. I will not omit to mention that the variation on the spot varies between N. 10° W. and N. 10° E. We have even found greater deviations. Most frequently it is about 5° W. The inclination is about 89° 20′. Captain Amundsen's second letter is dated May 22, 1905. In it he remarks:—This winter has not by far been so hard as the former. The sea-ice, which last year about this time measured about 380 cm., now is no more than about 170 cm. The lowest temperature we had in February, $-45°$. I commenced in February to circle the magnetic station, and have just finished this task. The magnetic variation house has been in uninterrupted activity. Absolute magnetic observations have been made daily, and at all temperatures. The meteorological registering instruments have been in function all the time. The zoological and ethnographical collections are constantly increasing. The magnetic variation house will be pulled down in the beginning of June, after nineteen months of uninterrupted activity.

In an article in the current number of the *Fortnightly Review* the Marchese Raffaele Cappelli sketches the growth of the ideas which led to the recent international conference on agriculture held, at the initiative of the King of Italy, at Rome. He enumerates also the advantages likely to accrue from the International Institute of Agriculture created on that occasion. At the close of the conference referred to, a protocol was signed by the representatives of all the Governments of the world—with the exception of some minor ones—favouring the establishment of the International Institute, and asking the respective Governments to adhere to the same. In the opinion of the writer of the article, the institute must aim at regularising, promoting, and generalising its internationalism. It must provide for the rapid and general diffusion of knowledge of technical improvements in the economics of production. The institute must further undertake the task of coordinating the efforts of many cooperatives scattered throughout the world, so that they may act in harmonious agreement. But most important of all will be the services which the international corporation will be able to render in the field of the economics of distribution. When once the institute is in full working order, it will be able to give an approximate idea of the stock in hand of each kind of produce, and so provide farmers with a trustworthy guide as to which crops they will be able to cultivate to the best advantage in a given year. The Marchese Raffaele Cappelli, in the course of his inaugural address as president of the International Congress of Agriculture held in Rome during 1903, adumbrated the present tendency towards international dealings in agriculture, and he is to be congratulated upon the successful inauguration of an institute which will realise the ends he has advocated.

We have received the second part of vol. lxi., and the first part of vol. lxii., of the *Verhandlungen* of the Natural History Society of Rhenish Prussia, Westphalia, and Osnabruck. Three papers, respectively by Dr. Krusch, G. Müller, and H. Westermann, are devoted to points connected with the coal-fields of Rhenish Westphalia and other districts coming within the purview of the society. Zoology is represented by a paper on the migrations of fresh-water planarian worms in the streams of the district, in which the author, Prof. W. Voight, distinguishes between the migrations of individuals and of species, and further subdivides the former class into accidental and periodical movements. In botany, Mr. F. Wirtgen descants on rare and disappearing plants of the Rhenish flora.

To the October number of the *Quarterly Journal of Microscopical Science* Dr. H. W. M. Tims contributes a suggestive paper on the development, structure, and morphology of the scales in certain bony fishes. Such a study, the author suggests, may not only throw light on the relationships of fishes, but it may also help to solve many problems in connection with the development of tooth-germs, for there seems little reason to doubt that scales and teeth are homologous. The question whether scales are ever replaced is raised in the course of the communication. Among the other contents of the same issue reference may be made to a paper by Mr. H. L. Kesteven on the developmental stages represented by the embryonic shell, or protoconch, of the gastropod molluscs.

In the October issue of the *Quarterly Journal of Microscopical Science* Messrs. Assheton and Stevens describe the minute structure of the placenta of an elephant belonging to Messrs. Sanger which in 1902 gave birth to a calf in the Zoological Society's Gardens. The duration of pregnancy appears to have been no less than twenty-eight months, although this is not absolutely certain. By an unfortunate error in Sir William Flower's article "Mammalia" in the ninth edition of the "Encyclopædia Britannica" (perpetuated in Flower and Lydekker's "Study of Mammals"), the proboscidean placenta is said to be non-deciduate. The deciduate character of the zonary

portion is, however, re-affirmed by the authors of the paper before us. On the other hand, the zonary placenta of the Sirenia is regarded as differentiated from the proboscidean type by being mainly, if not entirely, non-deciduate, although it is admitted that the two resemble one another in the long villi, which tend to remain in the walls of the uterus. Again, the resemblance of the proboscidean placenta to that of the Carnivora is deemed to be superficial, there being several important points of difference, the former having three areas of attachment in place of one. Another paper on development, by Dr. F. H. A. Marshall, deals with the mode of formation of the corpus luteum in various mammals.

In the *Proceedings of the Boston Society of Natural History* (vol. xxxiii., No. 7) Mr. A. H. Clarke gives a descriptive list of birds collected in the southern Lesser Antilles. Fishes collected in Tahiti form the subject of a paper by Messrs. Jordan and Snyder in the *Proceedings of the U.S. Nat. Museum* (No. 1422), a new species of Holocentrus being described and figured. In two other communications, Mr. C. H. Eigenmann discusses the phenomena of divergence and convergence in fishes (*Biol. Bulletin*, vol. viii., pp. 59 *et seq.*), and contributes a preliminary note on the fishes of Panama as considered from the standpoint of geographical distribution (*Science*, ser. ii., vol. xxii., pp. 18–20). As regards the first paper, the members of the American family Characinidæ present examples of both divergence and convergence, some forms being differentiated for carnivorous and others for herbivorous habits, while yet others approximate to fishes of quite different families. In the second paper it is concluded from the evidence of the fresh-water fishes that the Pacific slope fauna of tropical America was derived from that of the Atlantic slope subsequent to the shutting-off of a water-way between the Atlantic and Pacific Oceans.

In *Agricultural News* (September 23) reference is made to a memorandum written by Mr. M. Hesketh Bell, Officiating Governor of the Leeward Islands, on the occurrence of hurricanes in the West Indies. Mr. Bell points out that hurricanes do not occur in the West Indies so frequently as is generally believed, and that the accounts have in some instances exaggerated the amount of damage; further, he suggests that a scheme of insurance might be formulated which would offer great advantages to the landowners and at the same time prove acceptable to the underwriters.

The Bulletin of the Department of Agriculture, Jamaica, for September, contains an account of the discussion on cocoa cultivation which took place at the agricultural conference held in Trinidad, also notes on the fungoid and insect pests of cotton. The pests reported by the Hon. T. H. Sharp and Mr. S. Stricker include the cotton worm, which can be successfully treated when quite young with Paris green; cut worms, which attacked the roots, but also yielded to treatment with Paris green; and the cercospora fungus.

The report on the experimental agricultural work carried on in St. Kitts during the year 1903–4 has been published separately from the report on the botanic station. The superintendent, Mr. F. R. Shepherd, writes hopefully of the cotton industry and of the peculiar method generally adopted of growing the cotton as a catch crop on cane lands. Cotton seed was planted in May and June, and, after the first picking, the bushes were pulled up and sugar canes were planted. In the trials with varieties of sweet potatoes and yams, the very large differences between the yields of the better and poorer sorts furnish ample proof of the value of comparisons based on practical experiments to guide the cultivator in his choice of the best varieties.

Dr. E. B. Copeland has compiled a list of ferns belonging to the Polypodiaceæ recorded for the Philippine Islands, which is published in Publication No. 29 of the Bureau of Government Laboratories, Manila. The families are in accord with the "Pflanzenfamilien," but the subfamily Gymnogrammineæ is placed under the Asplenieæ. Of the sixty-two genera represented, naturally the largest is Polypodium, which is subdivided into six subgenera; a subgenus, Myrmecophila, is established for *Polypodium sinuosum* and *Polypodium lomarioides*, and this is followed by Drynariopsis, containing the species *P. heracleum* and *P. meyenianum*. Two species of the myrmecophilous genus Lecanopteris occur, and three species of Drynaria, a genus which is characterised by having pocket-leaves that collect detritus. In the same volume Dr. Copeland gives a selection of about twenty fungi for the islands, principally species of Coprinus, Phalliota, and Lepiota, which are said to be palatable and harmless.

We have received the first number of *Gas and Oil Power*, a new illustrated monthly review for factory owners and other power users. It contains an exhaustive article on the construction of internal combustion engines by Mr. R. E. Mathot, and a special table of the cost of power and light in the principal towns in England.

It has long been recognised that a wide field of profitable work has been opened for motors in connection with British railways. The earliest steam motor seen on a British railway began regular working in June, 1903, on the Fratton and Southsea line of the London and South Western Railway. It was designed by Mr. Dugald Drummond, and proved so successful that numerous other rail motor services have been introduced or sanctioned, for which an improved type of motor has been designed by Mr. Drummond. It seats eight first-class passengers and thirty-two third-class passengers. The total length of the car is 51 feet $2\frac{1}{2}$ inches, and it may be driven from either end. When empty the vehicle weighs 31 tons 11 cwt.

The annual progress report of the Geological Survey of Western Australia shows that in 1904, under the able direction of Mr. A. Gibb Maitland, much valuable work has been done in investigating the mineral resources of the colony. An examination was made of the Pilbara, Mount Morgans, Southern Cross, and Norseman goldfields. The occurrence of telluride ore, petzite, at Mulgabble, and of precious opal at Coolgardie was reported upon favourably, and the reputed tin finds at Cuballing and of petroleum on the Warren and Donnelly rivers were investigated. Analyses were made of manganotantalite from the Pilbara district, of scheelite from the Nullagine district, and of cobaltiferous asbolite, of no commercial value, from Greenbushes.

Excellent work is being done by the mines branch of the Canadian Government under the direction of Mr. E. Haanel, the latest departure being the inauguration of a series of monographs on the economic minerals of Canada. The first of the series, which has just been received, has been written by Mr. F. Cirkel, and deals with the occurrence, exploitation, and uses of mica. It forms a handsome volume of 148 pages, and is accompanied by a coloured geological map of the mica region of Ontario. It contains a synopsis of all the available practical inform-

ation on mica, and should lead to the development of the large mica tracts now known only by name, and to a search for the mineral in other parts of the Dominion. At the present time only a small proportion of the Canadian deposits are worked, many promising deposits having been abandoned on account of lack of experience on the part of those who directed the operations. In 1902 the value of the world's production of mica, in dollars, was as follows:—India, 507,770; Canada, 242,310; United States, 98,859; Brazil and other countries, 55,200; total, 904,139.

IN the *Smithsonian Miscellaneous Collections*, vol. xlix., Dr. A. G. Maddren has published a report of his expedition to Alaska last year in search of remains of the mammoth and other extinct mammals. The report contains a valuable description of the surface deposits of the country which will interest students of glacial geology, and there is an appendix of extracts from the published writings of Kotzebue, Beechey, and later travellers who have visited Alaska for a similar purpose. Dr. Maddren appears to have failed to obtain any important fossil bones, but his geological observations justify a few interesting conclusions. He thinks that the climate of the Arctic and sub-Arctic regions was never colder than it is at present. He is also convinced that there are no deposits of ice in Alaska which date back to the Pleistocene period, except the large glaciers. He has not observed any ice-beds interstratified with undoubted Pleistocene formations.

THE well preserved fossil ganoid fishes from the black Triassic shales of New Jersey, U.S.A., have long attracted attention. They are sometimes found in numbers so great as to excite public interest. The State geologist of New Jersey, in his last annual report (for 1904), has accordingly published a short account of these fossils, illustrated by photographs, and preceded by some elementary remarks on the study of fossil fishes in general. The chapter was prepared by Dr. Charles R. Eastman, and contains a useful summary of our knowledge of American Triassic fishes up to date. Notwithstanding the abundance of individuals, only six genera are represented—a curious contrast in this respect to any fish-fauna now existing. The species are also remarkably few, and some of them are difficult to distinguish on account of the crushing and distortion to which the fishes have been subjected during burial and fossilisation. Dr. Eastman does not describe any new forms.

THE Philippine Islands experienced a very destructive cyclone on September 26; the accounts that have hitherto reached us are rather meagre, and are extracted from the Manila *Cablenews* of September 28, which states that the storm was the worst that has occurred in the last twenty years. Some hundreds of houses were unroofed in Manila, where the wind is said to have reached a velocity of 103 miles an hour; at the naval station at Cavite damage was done to the extent of at least 100,000 dollars, but, so far as is known, the loss of life has not been very great. The Manila Observatory did good service in giving timely notice of the approach of the storm, notwithstanding that it was mostly dependent upon its own observations, as the telegraph lines in south-east Luzon were destroyed. The direction taken by the storm seems to have been from E.S.E. to W.N.W., and the rate of advance was about 12 miles an hour. The barometer fell from about 29·850 inches to 29·213 inches between 9h. p.m. of September 25 and 2h. p.m. of September 26; compared with the fall in our own latitudes, the amount, of course, is not excessive. The rainfall in twenty-four hours amounted to $4\frac{1}{4}$ inches.

PROF. J. HANN has made a very valuable addition to our knowledge of the meteorological conditions prevailing over the tropical regions of the earth by his publication of "Der tägliche Gang der Temperatur in der inneren Tropenzone," which has been reprinted from the seventy-eighth volume of the "Denkschriften der mathematisch-naturwissenschaftlichen Klasse der kaiserlichen Akademie der Wissenschaften" (Vienna, 1905). In his introduction he states that the mean temperatures of several stations in the tropics have been placed too high on account of inaccurate determinations of corrections which were applied to compute the true means. The object of the present investigation is therefore to determine the mean temperatures more exactly, making full use of the latest observations, and to employ a greater number of stations well distributed in longitude which were not previously available. Further, the two previous researches by Dove were published more than half a century ago, and no such complete work has since been published. In the present investigation the observations at thirty-five stations are utilised, and these are distributed over Africa, West Indies, Central and South America, south Asia and north Australia, and tropical oceans. To refer, even at the shortest length, to the method of reduction, the numerous tables, and the details given regarding each station utilised would considerably extend this note, but those interested in the investigation should make themselves acquainted with the volume itself.

A VALUABLE paper by Mr. S. R. Williams on the anatomy of *Boophilus annulatus* (Say), the tick which transmits the Texas fever of cattle, is published in the *Proceedings of the Boston Society of Natural History*, vol. xxxviii., No. 8, p. 313.

MR. WATKINS-PITCHFORD, bacteriologist and analyst to the Government of Natal, has published some observations on the germicidal action of copper salts and of bright copper. He concludes that in cupric sulphate, in the proportion of 1 part to 75,000 parts of water, we possess an agent which promises to be both efficient and safe.

Le Radium for October (2e année, No. 10) contains articles by Sir W. Ramsay, on a new element, radio-thorium; by M. Bloch, on the electric conductivity of selenium; by M. Charbonneau, on the transformation of currents of high tension into static discharges; and by M. Fraenkel, on the application of the X-rays in the study of the distribution of the blood vessels; together with the usual summary of researches connected with radio-activity. It is altogether an excellent number.

WE have received the second number of vol. i. of the Memoirs of the College of Science and Engineering, Kyoto Imperial University, containing reports on original work carried out by members of the university. The present number contains accounts of research in pure and physical chemistry, geology, engineering, and electricity.

THE *Psychological Review* (n.s., vol. xii., No. 5) contains an account, by Mabel S. Nelson, of an investigation of the difference between men and women in the recognition of colour and the perception of sound. As a result of many observations, the conclusion is formed that men are clearly superior in the recognition of blue and women possibly superior in the recognition of yellow. Both men and women hear farther with the right than with the left ear, men hearing better than women.

RECENT American mathematical journals contain some interesting papers. In the *Transactions of the American Mathematical Society* for July 10 M. Poincaré gives a

characteristic discussion of the geodesic lines on convex surfaces, with the aim of illustrating by a comparatively simple case the difficult questions of dynamic stability and instability in the problem of three bodies. Prof. E. W. Brown investigates a general method for treating transmitted motions and indirect perturbations such as arise when the action of the earth on the moon is modified by the influence of a planet on the earth's motion. In a long paper on the relation of the principles of logic to the foundations of geometry, Prof. J. Royce directs attention to a former paper by Mr. Kempe, which seems to have been largely neglected, and proceeds to develop the logical consequences of a theory suggested by, but more general than, Kempe's theory. Prof. Bromwich gives the classification of quadrics in hyperbolic and elliptic space, Prof. J. E. Wright writes on differential invariants, and Prof. Pierpont on multiple integrals. The remaining papers, by Messrs. Neikirk, Miller, Dickson, and Wedderburn, are all short, and bear upon the theories of groups and numbers.—In the July number of the *Annals of Mathematics* Dr. E. V. Huntington begins a series of articles on the continuum as a type of order, being a systematic elementary account of the modern theory, put together for the sake, not only of the mathematical student, but of non-mathematical students of scientific method; and Prof. Dickson proves a theorem in the theory of groups and applies it to the discussion of the real elements of certain classes of geometrical configurations.—The *Bulletin of the American Mathematical Society* gives in full a translation of M. Darboux's survey of the development of geometrical methods, the address delivered by him at the St. Louis International Congress of Arts and Sciences. In a short note Dr. Morehead proves that $F_n = 2^{2^n} + 1$ is not a prime when $n=7$, and states that he is in possession of a method for testing other similar cases. The only cases known to be primes are the first four, proved to be so by Fermat.

IN a paper published in the *Sitzungsberichte* of the Vienna Academy of Sciences (vol. cxiv. p. 553), F. von Lerch describes an experimental investigation of the electrochemical behaviour of thorium X, particularly as regards the manner in which it differs from the "induced activity" of thorium. When thorium X is dissolved in hydrochloric acid, and different metals are immersed in the slightly acid solution, the active substance which separates on the metal is not thorium X, but the induced activity; the same holds true of the product separated from the acid solution by electrolysis. On the other hand, from a solution of thorium X made alkaline with caustic potash or ammonia, thorium X is usually deposited either by a metal or under the influence of an electric current; but in certain cases, for example with amalgamated zinc, the induced activity is also thrown down. The production of thorium A and thorium B, and the relation existing between them, is also discussed.

IN vol. ix., p. 441, of the *Journal of Physical Chemistry* Messrs. E. S. Shepherd and G. R. Upton discuss the tensile strength of copper-tin alloys in relation to their chemical and physical structure. The test pieces made use of were heated for a prolonged period at different temperatures in order fully to attain the crystalline structure normal to those temperatures, the heating being followed by fixation of the properties by control of the rate of cooling. Among other results, it was found that prolonged annealing tends to coarsen the crystalline structure, to decrease the tensile strength, and to increase the ductility. In a second paper Mr. E. S. Shepherd gives an account of investigations of aluminium-zinc alloys, from which it is concluded that these series of alloys present no so-called definite compounds. There are, however, two series of solid solutions, that of zinc in aluminium and that of aluminium in zinc.

WE have received the annual address of the retiring president of the Society of Public Analysts, reprinted from the *Analyst* of April of this year. In the course of his address, Mr. Fairley referred particularly to the necessity that exists for a properly constituted authority to supervise the standard for drugs. In "Notes on the History of Distilled Spirits," published in the *Analyst* for September, Mr. Fairley includes an interesting collection of illustrations of ancient forms of stills used in several countries. The manufacture of whiskey was a matter of common knowledge amongst the people of Ireland when their country was invaded by the English in 1170–2, its Celtic name being "uisque beatha," meaning water of life. The distillation of brandy began to take form in France as a manufacturing industry early in the fourteenth century. Originally known as brandwine, brandewine, or brandywine, the term brandy came into use about 1657.

WE have received the first part of a "Natural History of the British Butterflies, their World-wide Variation and Geographical Distribution," by Mr. J. W. Tutt. The work is being published by Mr. Elliot Stock at 1*s*. net per part.

MR. R. W. ROBINSON has prepared a revised edition of "The Photographic Studio and what to do in it" by his father, the late Mr. H. P. Robinson (London: Iliffe and Sons, Ltd., price 2*s*. 6*d*. net). Few changes have been made, but references to some matters now out of date have been omitted. Amateur as well as professional photographers who wish to know something of the poses and practice of good portraiture will find Mr. Robinson's book a useful guide.

A SECOND edition of "Thermodynamique," by M. G. Lippmann, has been published in Paris by M. A. Hermann. The edition has been edited by MM. A. Mathias and A. Renault. The author endeavours first to elucidate the principles of thermodynamics in such a way that they may be applied intelligently. The facts upon which the principles rest are then explained. The general method of treatment adopted will enable the student to apply the principles of thermodynamics to particular cases, and thus render it unnecessary to search in a book for the right equation to use.

FIVE parts of a work on the fauna of New England, to be included in the occasional papers of the Boston Society of Natural History, have been received. The society is able to print this work by the aid of the proceeds of the Gordon Saltonstall fund. The first part is a list of the Reptilia, by Mr. Samuel Henshaw; the second of the Batrachia, by the same authority; the third is by Mr. Glover M. Allen, and deals with the Mammalia; the fourth, by Mr. Hubert L. Clark, is concerned with the Echinodermata; and the fifth is a list of the Crustacea, by Miss (or Mrs.) Mary J. Rathbun. When the series of lists is complete we hope to review them in these columns. Parts are to be published at irregular intervals, and though the details of the several lists will vary somewhat in the different groups, each list is to include, first, the accepted name (scientific and vernacular); second, reference to the original description, with record of locality; third, reference to an authentic description and illustration; and fourth, habitat and occurrence.

AMERICAN palæontologists are becoming more and more strongly convinced of the decisive character of the evidence afforded by extinct faunas of a comparatively recent con-

nection between South America, South Africa, and Australia. A short time ago, Dr. W. B. Scott, in the report of the results of the Princeton Expedition to Patagonia, announced his opinion that the fossil Santa Cruz insectivore Necrolestes is closely allied to the South African Chrysochloris, and that this relationship indicated a connection between South Africa and South America. Now Mr. W. J. Sinclair, of Princeton, in a paper published in the *Proceedings of the American Philosophical Society*, states unequivocally that Prothylacinus and the other marsupial-like carnivores of the Santa Cruz beds are true marsupials closely related to the Australian thylacine. He is, moreover, of opinion that the living South American marsupial Cœnolestes and its extinct relatives are annectant forms between diprotodonts and polyprotodonts, and are also not far removed from the ancestral stock which gave rise to the Australian phalangers. The existence of primitive opossums which cannot be regarded as ancestral to the modern South American forms is also an important determination. In view of the aforesaid relations, coupled with the evidence afforded by the invertebrate faunas, Mr. Sinclair considers himself justified in stating that "considerable evidence is now available to show that a land connection between Patagonia and the Australian region existed not later than the close of the Cretaceous or the beginning of the Tertiary, and it is possible that at this time the interchange of marsupials between the two continents was effected."

THE Carnegie Institution of Washington has published the first part of vol. i. of a "Bibliographical Index of North American Fungi," by Prof. William G. Farlow, professor of cryptogamic botany in Harvard University. This part extends from Abrothallus to Badhamia. The index owes its origin to the fact that in 1874 Prof. Farlow found it impossible to ascertain what species of fungi were known to occur in the United States, and he determined to bring together all references to North American species in the form of a card index. At the same time an authors' catalogue was started to include the titles of all works used in forming the catalogue of species. The latter catalogue was printed in 1887, and was followed by a supplemental list in 1888. A new edition with additions up to 1905 is in preparation. It was found impossible to obtain means of publication for the index until the Carnegie Institution offered to provide the funds. It is expected that the appearance of the present index will save many American institutions much time and money involved in the duplication of work. The index does not pretend to be a summary of all references to North American fungi, but is limited to those which concern the systematic mycologist, and does not include references to papers on fungicides and other technical subjects. We hope to review the index when its publication has been completed.

THE eleventh volume of the new series of the *Reliquary and Illustrated Archaeologist*, containing the four quarterly numbers published in 1905, is now available. Among contributions which will appeal to men of science are Mr. George Clinch's papers on the Neolithic dwelling and on Neolithic burial, Mr. John Patrick's essays on the sculptured caves of East Wemyss, and Mr. W. Heneage Legge's paper on glimpses of ancient agriculture and its survivals to-day. The journal makes a successful appeal to all who are interested in antiquities, architecture, the arts and industries of man in past ages, and in kindred subjects.

THE eighth volume of the *Transactions of the Rochdale Literary and Scientific Society*, dealing with the years 1903–5, has now been published. Among papers read before the society and printed in the volume the following may be mentioned:—Mr. T. Stenhouse, on the radio-activity of radium and other compounds; Mr. W. A. Parker, on the remains of fossil fishes found near Rochdale; Mr. W. H. Sutcliffe, on the bullion mine of the Upper Carboniferous rocks; Mr. C. W. R. Royds, on life in Antarctica; Mr. W. Baldwin, on the palæontology of Sparth Bottoms, Rochdale; and Mr. W. H. Pennington, on some ancient colouring matters. The latest report contained in the volume shows that the total number of members at the end of 1904 was 249, and that the society had a balance of about 66*l.* in hand. The society is to be congratulated upon its continued activity and upon the way in which, by lectures, field excursions, and other methods, it is disseminating an interest in scientific subjects.

OUR ASTRONOMICAL COLUMN.

A SUGGESTION FOR THE NEXT INTERNATIONAL SCHEME.—As the work on the international chart of the heavens is now nearing completion, Mr. W. E. Cooke, of the Perth (W. Australia) Observatory, suggests that astronomers should now begin to consider the next essential astronomical problem which should be attacked internationally. He suggests that the coordination of meridian observations is desirable, and outlines the plans on which such work might be commenced. These include the observation of fundamental stars, of about the sixth magnitude, in every part of the sky, and the formation of a main catalogue comprising, say, three stars to each square degree of the sky, that is, about 120,000 stars altogether. The accomplishment of this work would not only provide the necessary reference stars for future observations, but would give definite meridian work to a number of observatories which at present are performing it in a casual manner and often overlap each other's programmes (*Monthly Notices R.A.S.*, No. 9, vol. lxv.).

PHŒBE, THE NINTH SATELLITE OF SATURN.—Further details concerning the discovery and recognition of Saturn's ninth satellite are published by Prof. W. H. Pickering in No. 5, vol. liii., of the *Harvard College Observatory Annals*.

Prof. Pickering describes the taking and the reduction of each of the numerous plates on which the position of Phœbe has been measured. Up to the commencement of the present year 105 plates of Saturn had been secured with the Bruce telescope, and Phœbe had been recognised on 72 of these, the image on 69 of them being sufficiently well defined to be accurately measured.

On comparing these plates with others which were taken by Prof. Perrine with the Crossley reflector, it is seen that with plates having had equal exposures, and on which Phœbe is seen equally well, those taken with the reflector show stars of about one magnitude fainter than any to be found on the Bruce refractor plates.

Recent observations give the period of Phœbe as about 547·5 days, and the comparison of the observational results with the different sets of elements shows that with the revised elements the deviations are much smaller.

In No. 6 of the same volume Dr. F. E. Ross shows, in detail, the procedure followed in calculating the elements of Phœbe, and compares the three sets of elements which have been computed with the observational results. The discussion shows that slight changes in the previously determined eccentricity and period will bring the plates secured during 1898 into line with the more recent observations.

GRAPHICAL METHOD OF DETERMINING ALTITUDES AND AZIMUTHS.—A simple method of finding the altitude and azimuth of an observed body, the latitude of the observer and the declination and hour-angle of the object being known, has been devised by Mr. Littlehales, of the U.S. Hydrographic Office, and is briefly described in No. 6, vol. xxxiii., of the *Monthly Weather Review* of the U.S. Department of Agriculture.

The plan of solution employs a stereographic projection of the celestial sphere on the *plane of the observer's*

meridian, and by laying off the predetermined data on this projection—which is illustrated in the description—the observer may quickly find the required quantities.

The editor of the *Review*, Prof. Cleveland Abbe, commends Mr. Littlehales's method to the attention of all who have occasion to solve spherical triangles to the nearest minute of arc, whether in geodesy, navigation, astronomy, or general mathematical work.

THE METEORS OF BIELA'S COMET.—In No. 363 of the *Observatory* Mr. Denning directs attention to the probability of a strong shower of Andromedids this year. By quoting the observational results obtained during recent years, he shows that the shower has apparently developed into an important annual phenomenon, and he expects that the maximum display will take place on November 18, although a watch should be kept from November 17 to November 23. The position of the radiant is about R.A. $=25^{\circ}$, dec. $=+43^{\circ}$, *i.e.* near to γ Andromedæ.

THE MAGNITUDE OF η ARGÛS.—From a series of observations made at Johannesburg during May and June, Mr. R. T. A. Innes found the magnitude of η Argûs for 1905·5 to be 7·67, and its colour, on Chandler's scale, to be $7\frac{1}{2}$. On comparing these with the observations made in 1896, he finds that the change, if any, since that date is quite insignificant (*Monthly Notices R.A.S.*, No. 9, vol. lxv.).

ENGINEERING AT THE BRITISH ASSOCIATION.

BEFORE dealing with the actual work of the section, it is desirable to put on record the fact that several of the special lectures arranged by the council were exclusively engineering in their character, namely, the lectures delivered at Johannesburg by Prof. Ayrton on the distribution of power, and by Prof. Arnold on steel as an igneous rock, and the address given at Kimberley by Prof. Porter on the bearing of engineering on mining. In judging, therefore, the work done by Section G during the South African meeting, the effect produced by these lectures, delivered in all cases to large audiences, must be kept in mind.

At Cape Town the first paper read was by Mr. C. H. Smith, on colonial Dutch architecture. In this paper Mr. Smith gave a brief account of the history and development of the early architecture of Cape Colony. He pointed out that building materials were exceedingly difficult to obtain, but in spite of all difficulties the early Dutch settlers, who were men of excellent taste and education, commenced their labours on true lines. Although drawing upon the well known principles of Dutch and Batavian architecture, they adapted their buildings to the new country, and developed a style distinctly their own. It was to Governor Simon van der Stel that many of the most picturesque houses in the Cape Peninsula were due. He and his son, who succeeded him, were great builders of houses and planters of trees. The author showed a number of slides illustrating some of the quaint old houses in the Cape Peninsula and its neighbourhood, in particular at Stellenbosch, famous for its beautiful situation and surroundings. This paper proved a great attraction, and drew a large audience.

The paper by Prof. Biles, on steam turbines as applied to ocean liners, was the next dealt with. When this paper was first promised, the author hoped that detailed results of the running of the only two completed turbine ocean steamers would have been available for his paper; unfortunately this was not the case, though Prof. Biles stated that the results so far obtained had completely justified the adoption of the turbine on ocean steamers. He pointed out that such a great revolution as a change from reciprocating engines to turbine engines had never before taken place in such a short time. The author gave figures dealing with the gain in economy from an engineering point of view; in the case of the turbine steamers the *Londonderry* and the *Manxman*, as compared with the *Antrim* and the *Donegal*, designed at the same time, and having reciprocating engines, the *Londonderry* showed a total economy of 2·4 per cent. and the *Manxman* of 7·7 per cent. Prof. Biles, in summing up the work which had been done so far, stated that he was of opinion that there was every indication that in the largest installations on ocean liners there was an economy of power and cost in the use of turbines as well assured as in the case of channel steamers, and that there was little doubt that the turbine would completely displace the reciprocating engine in all moderate and high-speed liners.

Mr. How, in his paper on roller bearings, which was read in his absence by the Recorder of the section, gave some results of recent tests on line shafting when fitted with roller bearings, and on tramway and railway vehicles. In the Birmingham electric tramways it was stated that a saving of 24·3 per cent. of tractive power per ton of load was obtained, and that the net saving per car per annum would amount to 38*l*. 16*s*. 3*d*. Several railway companies had experimented with roller bearings, and in all cases a considerable economy in coal consumption had resulted. On the Liverpool overhead railway, tests proved that the reduction per ton mile of coal consumption was equal to 9 per cent., and that longer trains could be employed.

A very interesting paper was that on motor-cars in South Africa, by Mr. A. T. Hennessey. The chief object of the author was to make clear the special points in car design and construction to which attention should be paid if the motor-car is to be a success in South Africa. So far, of course, all the cars in use there are imported cars, and are built for conditions which prevail in Europe and America, and not for the conditions which prevail in South Africa. In comparing steam cars with petrol cars, Mr. Hennessey came to the conclusion that the latter were the more suitable for South African conditions; in fact, he was of opinion that the shortcomings and disabilities of the steam car were greatly accentuated by the climatic and road conditions of South Africa. The question of the cooling of the cylinders in a semi-tropical country, with roads carried up very steep hills, is most important, and very few imported cars have anything like enough water-cooling capacity. As regards springs, also, there has been great difficulty, and motorists at home have very little idea as to the strain placed upon the springs by the ordinary South African roads. In a motor-car excursion, arranged for the visiting members of the association on the Saturday of the Cape meeting, along the beautiful coast road which runs from Cape Town to Hout Bay, owing to a landslip on the mountain-side, caused by the heavy rains of July and August, the visitors had an ample opportunity of testing the kind of strain to which motor-cars are subjected in South Africa; the cars had to charge through a mass of liquid mud and stones, probably 12 inches in depth, and extending for some 100 yards along the road. In many country districts the author pointed out that it is a common occurrence for the centre of the track to be from 6 inches to 12 inches higher than the sides, which would render it impossible for a car with only a 5-inch under-clearance, which is the maximum clearance of many cars, to travel over these country roads. This paper provoked a very interesting discussion, in which the claims of the steam car were strongly upheld by one or two of the speakers.

The most important paper read before the section in Cape Town was Mr. Tippett's, on Cape Government railways. The author is one of the leading engineers in the Cape Government Railway Service, and the Government gave him every facility in the preparation of his paper. The paper formed practically a complete record of the growth of the railway industry in Cape Colony, and of the methods adopted in surveying, in constructing, and in working the railways. It bristled with statistics and figures, and there were a number of excellent diagrams and reproductions of photographs to illustrate the paper. It will form a most valuable paper for reference purposes to anyone engaged in studying the conditions of railway construction and working in our South African colonies. It is obviously impossible to give anything but a very faint notion of the contents of a paper of such length and importance in a brief summary, such as this is, of the proceedings of the section. One or two salient points to which the author devoted much attention may, however, be briefly dealt with. The one is the question of gauge. He pointed out that the original line from Cape Town to Wellington, now part of the main western system, which was constructed by a private com-

pany, was built on the 4 feet $8\frac{1}{2}$ inch gauge, but when the Government took over this line, and decided to take in its own hands the construction of the railways, acting on the advice of a strong commission, it decided to adopt 3 feet 6 inches as the standard gauge. That gauge has been adhered to throughout South Africa with the exception of one or two short branch lines, which are on the 2-feet gauge, and at the present time a 2-feet gauge line is in process of construction between Port Elizabeth and Avontuur, a coast line, which will probably be eventually extended to Cape Town. The wisdom of constructing a line such as this on a 2-feet gauge seems rather doubtful, but the large bridges on it have been put up of such a strength and of such dimensions as would enable a 3 feet 6 inches gauge to be adopted later on. Another point on which the author laid great emphasis was the system of surveying which it was necessary to adopt in a country where Ordnance maps are at present unavailable. The colonial-trained surveyors are able to carry out work with rapidity and with accuracy by the use of the tacheometer only, which would be impossible in the hands of surveyors trained only in our home methods. If a country like South Africa is to be developed by railways, it is obvious that the cost of construction must be kept down to the lowest possible figure, and, therefore, tunnels, heavy cuttings, and heavy banks must be avoided. All the members of the visiting party who travelled over the main lines in all the colonies during the visit of the association were struck with the extraordinary surface character and curvilinear meanderings of the railway lines, although by this system of construction the actual length of the lines has been in many cases increased, and the possible speed at which trains can be worked has been lessened; nevertheless, when one compares travelling, both as regards time and cost, on these lines with that in the old days with ox or mule waggons, there is no doubt that the wisest plan was to sacrifice, for the time being, possible speed for economy in construction. The Cape lines, and in fact all the lines which serve the Transvaal, suffer from the same disability as the steamer lines which ply between Europe and the Cape—heavy goods traffic is all in one direction. No less than 80 per cent. of the goods traffic on the Cape Government railways is in the shape of up-country traffic; this means necessarily a large number of empty waggons returning to the coast, and must inevitably increase freight charges.

The section opened its proceedings at Johannesburg with the president's address, which was devoted to irrigation. The subject is one of such paramount importance to South Africa that no happier choice could have been made of a president for Section G than that of Sir Colin Scott-Moncrieff. Naturally the examples selected by the president for illustration of the problem of irrigation for agricultural purposes were India and Egypt, although he had also a good deal to say with regard to the system in force in the United States and in Italy. It is to be hoped that the information placed at the disposal of South African engineers by this address will not fail to influence the trend of legislation on this question in our South African colonies.

Sir William Preece gave an interesting account of the present condition of wireless telegraphy, and his paper, bringing all the information on this question up to the most recent date, was a welcome contribution to the transactions of the section. Sir William Preece has on previous occasions contributed papers on this question to the section, and has kept the section well informed of the gradual progress in the evolution of wireless telegraphy as a practical mode of communication.

Prof. Perry's paper on the accidental breakage of winding ropes in mines concluded the first day's work at Johannesburg. In this paper certain examples were worked out in full, and in an appendix to the paper the whole of the mathematical treatment of the problem was given by the author.

The second day's proceedings were opened by Mr. Hammond with a paper on electrical power distribution for the Rand. After alluding briefly to the present tendency at home, and at such situations as the Niagara Falls, to construct large central supply stations, the author referred to the fact that he was surprised to find that this problem had not yet been taken up on the Witwatersrand. Two points were, therefore, discussed in the paper—one was whether the working of the mines could not be cheapened by the extended application of electrical power, and the second, as a corollary, whether such electrical power could not be more economically produced by a central station rather than by each mine, or group of mines, laying down its own plant. In colliery work in Great Britain there is, and has been for the last year or two, a steady growth in the application of electricity to haulage and other work in the coal mines, and the author advocated the adoption of electrical winding for the Rand mines. He also pointed out that a considerable increase of efficiency would be obtained by the abolition of the surface compressed-air plant, and by the introduction of electrically driven compressors, placed underground near the actual workings. Mr. Hammond showed that the total requirements of the Rand mines worked out at a very high figure of horse-power hours (400,000,000), and he proved by further figures that a central power station would thus have a very favourable load factor. Assuming a diversity factor of 60 per cent., and a 20 per cent. loss in distribution and transformation, he estimated the plant capacity at the central station would be 60,000 kilowatts. Basing his further calculations on these figures, the author then proceeded to work out fully the costs of generation and distribution, the revenue which could be expected, and the corresponding financial results. In concluding his communication, which was one of great value, Mr. Hammond referred to the case of the well known central power station at Newcastle-upon-Tyne, and expressed the opinion that if on the river Tyne, where coal was available in large quantities at very low rates, it paid to displace steam power by electric power, still more so would it pay on the Rand.

Mr. Dew read a short paper on water-power plants, Pilgrim's Rest, Transvaal. In this paper the author gave a list of plants in actual operation with the horse-power developed, the type of prime mover, quantity of water, and head, and dealt with a number of points of special interest in the running of such plants.

On the Friday, the last day the section met, the first paper was by Mr. C. W. Methven, on South African harbours. This paper was one of great importance, and must have involved an immense amount of work in its preparation. Practically a complete history of the harbours which have been built up round the South African coast was given. As the author pointed out, there is a remarkable absence of deep-water indentations forming natural harbours between Cape Town and Delagoa Bay, and therefore all the harbours have had to be artificially created. After giving a brief account of the Table Bay works, and the extensions now being carried out by Mr. Hammersley Heenan, the author referred to the Algoa Bay works, and the remarkable stride which had been made within the last few years in the commercial prosperity of this harbour, in spite of the difficulties due to its exposed condition and the heavy seas which frequently make approach almost impossible. Mr. Methven then discussed very fully the formation and treatment of sand-bars at the mouths of the rivers and lagoons on the south-east African coast, which render the construction of harbours and their maintenance such a difficult engineering problem.

Another valuable paper taken at this sitting was one by Mr. C. D. H. Braine, on irrigation in South Africa, dealing with the important question of the duty of water used for irrigation purposes. The author stated that there was very little information on the subject as regards South African practice, and that therefore irrigation engineers in South Africa had to be guided to a great extent by experience in other countries, such as America, Spain, India, &c. He pointed out how unskilled irrigation frequently means a waste of from 25 per cent. to 50 per cent. of water, and that many crops were actually impaired by excessive irrigation. For South Africa he was of opinion that the duty actually used on the land could be safely taken at the rate of 285 acres per cubic foot of water per second, and he quoted statistics from other countries to show that this was a reasonable allowance. To show the value of irrigation in South Africa, the author gave figures as to increase in land values;

land valued in the dry, unirrigated state at anything from 10s. to 30s. per acre was valued at rates of from 25l. to 100l. per acre when properly irrigated.

The concluding paper, by Mr. J. H. Ronaldson, dealt with the copper deposits of Little Namaqualand. The author pointed out that from the very early days it had been known that this district in the extreme west of Cape Colony, lying just south of the Orange River, and bounded on the west by the Atlantic Ocean, was a copper-producing one. As early as 1685 one of the Dutch governors dispatched a party to explore the country, but it was not until 1855 that successful work was begun. The district in which the copper mines are situated lies in the hilly ground about 50 miles from the coast, and is connected with Port Nolloth by a 2 feet 6 inches narrow-gauge railway, the property of the Cape Copper Co. During the year 1904 about 85,000 tons of ore were raised, the percentage of copper ranging from 26 per cent. to as low as 3·6 per cent. T. H. B.

ANTHROPOLOGY AT THE BRITISH ASSOCIATION.

THE South African meeting will long be memorable to members who are especially associated with Section H, not so much on account of the high quality and interest of the papers read (though, as will be seen, these were often of considerable importance) as because it afforded an opportunity of examining, measuring, and photographing specimens of the native races, and (what was still more valuable) of visiting Bantu kraals, seeing the native in his ordinary surroundings, and witnessing some of his ceremonial rejoicings. These visits and investigations were outside the strictly sectional work, and can hardly be detailed here; but they cannot fail of permanent results in an increased comprehension of the conditions of native life and of the great problems, scientific, social, and political, connected with the native peoples of South Africa, by all who were privileged to take part in them.

Dr. Haddon's presidential address, delivered on August 16 at Cape Town, has already been printed in full in NATURE (September 7, p. 471), and need not be further referred to here than to point out its exceptionally comprehensive and useful character as a summary of our present information as to the process by which South Africa was peopled, and a sane, earnest, and timely appeal for scientific study on the spot of peoples, some of which are actually vanishing before our eyes, and the others of which are undergoing at the hands of the white race a process of so-called civilisation which will issue in a few years in the total destruction of their ancient institutions and beliefs.

The first paper read was by Mr. E. Sidney Hartland on the totemism of the Bantu. He pointed out that to the French Protestant missionary Casalis belongs the honour of being the first to note the similarity between the totemic practices and belief of the North American Indians and those of the Bantu peoples. The object of the paper was to examine the latter practices and belief, so far as they have been recorded, with the view of ascertaining how far they extend and what evidence there is of their former existence where they are no longer preserved; whether there is any essential difference between the practices and belief of the Bantu and what is generally understood by totemism elsewhere; and lastly, the process of decay. The conclusions arrived at were that, though there is little in what is recorded of the Bantu on the western side of the continent down to the southern boundary of Angola which points directly to totemism, there is sufficient to suggest that it once generally prevailed there, and that its disappearance is due to contact with the Negro; that with regard to the eastern and northern Bantu there can be no doubt about the prevalence of totemism which, though now in decay, corresponded in all essential particulars to that of other races, such as the North American Indians and the Australians; and that its decay was due to the change in the reckoning of kinship from reckoning through the mother only to reckoning through the father only, and to the ancestor-worship which had arisen upon the new social basis thereby laid.

Mr. L. Peringuey, curator of the South African Museum, followed with an address on the Stone age in South Africa. The substance of this address has been published in the volume entitled "Science in South Africa." It was illustrated by a carefully selected series of specimens from the museum, which were examined with interest in the course of an indecisive discussion which followed.

The session on Thursday, August 17, was opened by Mr. Henry Balfour with a paper on the musical instruments of South Africa. Mr. Balfour is already known as an authority on the evolution of the musical bow. In the bow of the Damaras, which is upon occasion temporarily converted into a musical instrument, he recognised an example of the earliest stage of development of a long series of instruments culminating in various forms of the harp. Other types of musical instruments were discussed, of which the most interesting, as well as the most enigmatical, was the *goura* of the Bushmen, an instrument substantially identical with the *iseba* (or *lesiba*) of the Basuto and some other Bantu tribes. On this instrument the writer had little to add to what he had previously published in the *Journal of the Anthropological Institute*. Generally as to the development of musical instruments, stress was laid on the importance of exact information with the view of determining the geographical distribution and evolution of the various types.

Miss B. Bullen-Burry read a paper discussing the social and political questions raised in the United States by the existence of the Negro in the midst of a white population. This paper dealt with an aspect of ethnology rarely brought before the section; but the state of things described by the writer and the problems involved are so similar to those even more critical in character now engaging the attention of politicians in South Africa, and on the satisfactory solution of which depends the future of the country, that it is much to be regretted that the writer had so small an audience.

On Friday, August 18, Prof. von Luschan read a paper on artificial deformation in Africa, abundantly illustrated by lantern slides. He traced all deformations of the human body to a foreign source, except possibly the tattooing in relief and the deformations of the lips.

The Rev. Canon Crisp presented a paper (which was read by the Rev. J. S. Moffat) on the mental characteristics of the Bechuana. He dwelt on the peculiarities of Sechuana grammar and construction, illustrating them by various examples. The Bantu languages will express any idea, however esoteric, and will do it with extraordinary precision and often with great felicity. A foreigner who has acquired one of them will often leave his own language to use a Bantu word, because it conveys his thought more aptly and tersely. Bantu proverbs and metaphors are often most incisive, emphasising with much power and delicacy what it is intended to say. The Bechuana are accustomed to use their proverbs without any introduction, their rapidity of thought enabling both speaker and hearers at once to locate the idea to be conveyed. They are masters in the art of destructive criticism, and their native shrewdness, observation, and wit render them dangerous disputants. Instances of the facility with which Bantu acquire European learning and adapt themselves to European thought were given. This paper aroused much interest on the part of the over-sea members who heard it, and numerous questions on details were addressed to Canon Crisp, though of discussion strictly speaking there was none.

A short paper by Mr. William Grant was read giving an account of a visit in March, 1894, to Magato, the then chief of the Mawenda in the Transvaal. The business of the Cape Town meeting was then closed by the president with a few appropriate words of appreciation of the assistance rendered by Mr. Peringuey, who had kindly acted as local secretary, and of the kindness with which the visitors from the Mother Country had been received.

The session at Johannesburg was opened on Tuesday, August 29, with a paper by Dr. S. Schönland, on arts and crafts among the natives of South Africa, containing a summary of present knowledge on the subject.

A paper followed by Mr. W. A. Squire on the art of the Bushmen. It was illustrated by the exhibition of copies of a number of Bushman drawings, on which the author

commented. The methods by which the artist achieved such wonderfully spirited and life-like results were simple indeed. Coloured earth, pounded stones, charcoal, blood, and bird-fat constituted his pigments. A flat stone was his primitive palette. His brushes were perhaps made of the coarse hair of the male wildebeeste or buffalo. Elsewhere he scratched on the walls of his rock-shelter with a stone a little harder than the surface to be adorned. Much interest is obviously shown in the details. Obscenity, as such, is rare. By way of illustration of the technique of these drawings, a copy of a Bushman battle picture from the Natal side of the Drakensberg Range, near Bushman's Pass, and an unpublished drawing by a member of the Kamilaroi tribe of eastern Australia were exhibited, and compared to the disadvantage of the latter in strength, vividness, and accuracy of portrayal. Finally, the object and meaning of the drawings were touched upon, but not discussed, by the author, possibly because too little is known as yet; perhaps too little ever will be known to give rise to more than conjecture. It may be observed, however, that the late Mr. G. W. Stow, the author of a book recently published on the natives of South Africa, formed a large collection of copies of Bushman drawings. These were examined by the president and several members of the section after the meeting was over, and a strong desire was expressed that they should be published. If this could be done, a careful collation might result in some conclusions as to the motives which prompted and the circumstances which developed these remarkable exhibitions of artistic power by a people usually accounted so low in the scale of humanity—conclusions which might, moreover, throw unexpected light on the similar memorials left by the palæolithic people of central France.

A descriptive summary of recent discoveries of stone implements in South Africa was presented by Mr. J. P. Johnson.

Mr. A. E. Mabille read a paper on the Basuto. As a grandson of the famous missionary Casalis, who had lived (except for a few years when he was completing his education at Paris) his whole life in touch with the people, the author was specially fitted to deal with the subject; and the paper was valuable for the statistics it contained and the picture it offered of the present condition and customs of the Basuto under the British protectorate. In the discussion which followed some exception was taken to the use of the word *Modimo* for *God*, but the author defended its use on the ground that it was the word long ago adopted by the missionaries, and, whether rightly or wrongly adopted at that time, its use was now fully understood and accepted among the Basuto themselves.

On Wednesday, August 30, Prof. von Luschan read a paper on the racial affinities of the Hottentots, in which he contended, mainly on the evidence of the Hottentot language, that the Hottentot were a Hamitic people which had come into contact with the Bushmen and absorbed Bushman characteristics. Apart from a few roots and clicks, he declared the Hottentot language to be strictly Hamitic. On the physical side, the loss of their original high stature and the acquisition of steatopygia and of the spiral curled hair of the Bushman have been the penalties of intermarriage with the pigmy people.

Mr. Randall MacIver exhibited and described a number of lantern slides of the Rhodesian ruins. His report on his recent examination of the ruins was read in greater detail at an evening meeting at Bulawayo. It may here be said, however, that he has with some probability established by his researches the native origin of the ruins, and shown that most of them are of no great antiquity, in no case going back to more than 600 or 700 years. They are essentially Bantu kraals in stone. Great Zimbabwe he identified with the capital of Monomotapa, as described by the earlier Portuguese travellers. All the problems connected with the ruins are not yet solved. We are still ignorant what gave the artistic and military impulses to the erection of these structures, against what enemy they were planned, and what led to their ruin and abandonment. These matters can only be determined, if at all, by accurate scientific exploration, and not by mere speculation like much of that which has been hitherto wasted upon these mysterious remains.

Not the least important day in this section was Friday, September 1. Besides papers by the well known missionary M. Junod on the Thonga tribe (illustrated by an interesting exhibition of native music, both vocal and instrumental), and by Mr. J. W. Shepstone, C.M.G., giving a general sketch of the native tribes, two striking communications were read, the one by the Rev. E. Gottschling on the Bawenda, and the other by the Rev. W. C. Willoughby on the totemism of the Bechuana. Mr. Gottschling's paper was partly historical, partly descriptive, and gave a number of particulars hitherto unpublished relating to the Bawenda, a tribe of Bantu in the north-east of the Transvaal, and their customs and beliefs. Some of the details were of quite extraordinary interest. Mr. Willoughby's paper was a discussion of a number of points connected with the totemic practices and of the relation to them of various ceremonies not usually regarded as totemic in origin, in which oxen and certain vegetables play an important part. The writer's conclusions were open to much debate, for which little time was found. The paper, however, as a whole was so suggestive, directing attention to aspects of the Bantu religious ceremonies other than those from which they are usually regarded, that it will be a great pity if this paper, as well as that of Mr. Gottschling, be not published in some form accessible to anthropologists.

The business of the section was wound up with graceful words of thanks by the president to the local committee, and in particular to Mr. A. von Dessauer, the local sectional secretary, to whose energy, forethought, and organising ability the success of the Johannesburg meeting was so largely due.

THE SOLAR OBSERVATORY ON MOUNT WILSON, CALIFORNIA.[1]

In a report entitled "A Study of the Conditions for Solar Research at Mt. Wilson, California," an outline was given of the circumstances that have resulted in the establishment of a solar observatory on Mount Wilson by the Carnegie Institution of Washington. At the recent annual meeting of the board of trustees, a grant of 150,000 dollars was authorised, for use during 1905. It is expected that the first equipment will cost about twice this sum, and that important additions will result in the future from the operation of a large and well appointed instrument and optical shop.

In April, 1904, a grant of 10,000 dollars was made by the executive committee of the Carnegie Institution for the purpose of bringing the Snow telescope to Mount Wilson from the Yerkes Observatory. An expedition for solar research was accordingly organised under the joint auspices of the University of Chicago and the Carnegie Institution, with the understanding that the funds granted by the Carnegie Institution would be used for the construction of piers and buildings, and for other expenses incidental to the work, while the University of Chicago would furnish the instrumental equipment and pay the salaries of some of the members of the party.

It is a fortunate circumstance that the construction and use of a great reflecting telescope, with a five-foot mirror, is in the general plan of research laid down for the Solar Observatory. In "Year Book" No. 2 (p. 49) of the Carnegie Institution may be found a report on this subject, prepared at the request of Profs. Boss and Campbell, my colleagues on the committee, and improved in many particulars as the result of their criticisms. The prime object of the Solar Observatory is to apply new instruments and methods of research in a study of the physical elements of the problem of stellar evolution. Since the sun is the only star near enough the earth to permit its phenomena to be studied in detail, special attention will be devoted to solar physics. It is hoped that the knowledge of solar phenomena thus gained will assist to explain certain stellar phenomena. Conversely, the knowledge of nebular and stellar conditions to be obtained through spectroscopic and photographic investigations with the

[1] Abridged from No. 2 of "Contributions from the Solar Observatory of the Carnegie Institution of Washington," by Prof. G. E. Hale, director of the Observatory

five-foot reflector should throw light on the past and future condition of the sun. All the principal researches will thus be made to converge on the problem of stellar development. The name "Solar Observatory" is regarded as appropriate, since the spectroscopic study of stars and nebulæ, to be carried on in connection with the solar work, are essential elements in any attempt to determine the mode of origin, the development, and the decay of the sun as a typical star.

How, then, shall we attack in an effective manner the complex problem of stellar evolution? It goes without saying that I can offer no general answer to this question; I can only point out the three principal lines of attack which we hope to pursue at the Solar Observatory. These involve:—

(1) The more complete realisation of laboratory conditions in astrophysical research, through the employment of fixed telescopes of the cœlostat type, and through the adoption of a *coudé* mounting for the five-foot reflector. This should permit (*a*) the use of mirrors or objectives of great focal length, thus providing a large image of the sun for study with spectroscopes and spectroheliographs; (*b*) the use of long focus grating spectroscopes, mounted in a fixed position in constant temperature laboratories, for the photography of stellar spectra requiring very long exposures; (*c*) the use of various laboratory instruments, such as the radiometer, which cannot be employed in conjunction with moving telescopes.

(2) The development of the spectroheliograph in the various directions suggested by recent work at the Yerkes Observatory, including the photography of the entire solar disc with dark lines of hydrogen, iron, and other elements; further application of the method of photographing sections of flocculi corresponding to different levels; special studies of sun-spots, &c.; and daily routine records of calcium and hydrogen flocculi and prominences.

(3) The construction of a five-foot equatorial reflector, with *coudé* mounting, and its use in the photography of nebulæ, the study of stellar and nebular spectra, and the measurement of the heat radiation of the brighter stars.

It was originally intended that a prolonged series of determinations of the solar constant, extending over at least one sun-spot period, should be made an important feature of the observatory's work. The plans outlined in "Year Book" No. 2 accordingly included an equipment at Mount Wilson for this purpose, and suggested, in harmony with Dr. Langley's view, that provision be made for two additional stations, one near the summit of a high mountain, at an elevation of about 12,000 feet, the other at a much lower level on the same mountain. The principal purpose of these two stations was to measure the atmospheric absorption, in order to eliminate it from the solar constant determinations. The recent developments of Dr. Langley's researches at Washington have led Mr. Abbot, who is associated with Dr. Langley in the work, to the conclusion that entirely satisfactory results can be obtained there by the method employed. The poor atmospheric conditions with which the Washington observers have so successfully contended, and the disturbances arising from ground tremors in the heart of a large city, would be largely eliminated at Mount Wilson. For this reason it seems probable that results of higher precision could be obtained at this site.

In addition to the above mentioned observations, provision will be made at Mount Wilson for various laboratory investigations necessary in conjunction with solar research. In view of the importance of securing a complete record of solar phenomena when magnetic storms are in progress, suitable magnetic apparatus, recommended by Dr. L. A. Bauer, in charge of the department of terrestrial magnetism of the Carnegie Institution, will be installed at a sufficient distance from the electrical machinery.

As no description of the Snow telescope has been published, the present brief account may be prefaced by a statement regarding the construction of the telescope.

In 1900, after Prof. Ritchey had succeeded Prof. Wadsworth as superintendent of instrument construction at the Yerkes Observatory, a cœlostat with mirror of 15 inches (38 cm.) aperture was made, from Prof. Ritchey's designs, for the total solar eclipse of that year. This gave such satisfactory results that the plan of constructing a large cœlostat was again taken up. Unfortunately, however, no funds were available for this purpose. In 1901, during a visit to the observatory of Prof. Cross, chairman of the Rumford committee, I showed him the details of the instrument, as worked out by Prof. Ritchey. The design called for a cœlostat of 30 inches (76 cm.) aperture, with second plane mirror of 24 inches (61 cm.) aperture, the latter mounted so as to slide north-east and south-west on rails lying east of the cœlostat. The concave mirror, to which the light was reflected from the second plane mirror,

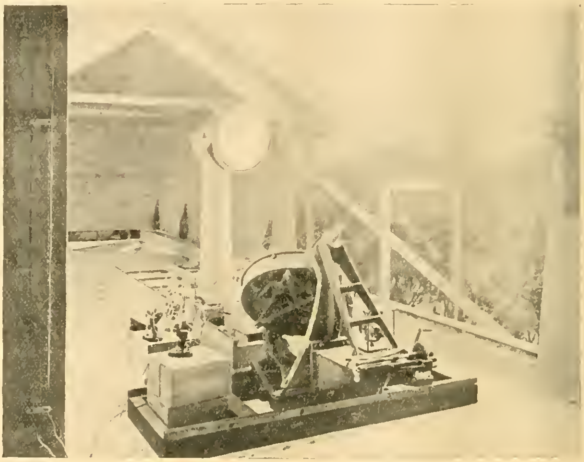

FIG. 1.—The Snow Telescope when mounted at the Yerkes Observatory.

had a focal length of 61 feet, and a second concave mirror, of 165 feet (50·3 m.) focal length, was also to be used.

At the kind suggestion of Prof. Cross, a grant of 500 dollars was made by the Rumford committee in aid of an investigation to be undertaken with this telescope. Subsequently, through the kindness of Prof. Pickering, chairman of the Draper committee, two other grants, of 500 dollars each, became available. With these funds, helped out by small amounts obtained from other sources, the work was begun.

A gift of 10,000 dollars from Miss Helen Snow, of Chicago, in memory of her father, the late George W. Snow, provided sufficient funds to complete the telescope and to instal it in a suitable house. The cœlostat was mounted on a brick pier, at a height of 15 feet (4·57 m.) above the ground. In Prof. Ritchey's design of the previous instrument the rays were reflected in a north-easterly direction from the cœlostat mirror to a second plane mirror, which sent them toward the south-west to one or the other of the concave mirrors. In designing the Snow telescope, a new arrangement of the second mirror was adopted by Prof. Ritchey, at the suggestion of Mr. C. G. Abbot. As Fig. 1 indicates, the light is reflected upward and to the south from the cœlostat mirror to a

second plane mirror, mounted in a fork at the upper extremity of an iron column, on a carriage which can be moved along heavy iron rails. The position of this carriage on the rails depends upon the declination of the observed object; with a low sun the second mirror stands close to the cœlostat, but with a high sun it must be moved away in order to intercept the reflected beam. The cœlostat itself may be moved east or west on its own rails, so that a low object near the meridian may not be hidden by the second mirror or its support.

With the exception of the solar and stellar spectroscopes, for which suitable gratings could not be obtained, the Snow telescope was practically completed in the autumn of 1903. On October 3 of that year it was formally presented to the University of Chicago by Miss Snow, in the presence of a number of guests.

In designing the new cœlostat house on Mount Wilson I was influenced by two principal considerations:—(1) The importance of placing the cœlostat as far as possible above the ground, which had been indicated by observations made with a telescope in a tree at elevations ranging from 20 feet to 70 feet; (2) the importance of constructing the house in such a way as to reduce to a minimum the heating and the radiation of the floor, walls, and ceiling, with the purpose of keeping the air within the house at the same temperature as the outer air.

The cœlostat, and the supports for the plane mirror and the 60-feet concave mirror, are now in place on the piers, but heavy storms have prevented the mirrors from being mounted. The concave grating stellar spectrograph is nearly ready to be set up, and work is well advanced on the smaller of the two spectroheliographs. The ultraviolet glass prisms and lenses for the stellar spectrograph have been completed by the Carl Zeiss Company, and orders have been placed for the optical parts of the 30-feet spectroheliograph and the Littrow spectrograph. Through the courtesy of the president and trustees of the University of Chicago, the Snow telescope and some of its accessories will be used by the Solar Observatory for some time. It will subsequently be replaced by a similar telescope constructed in our own instrument shop.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The following examiners have been appointed in the science schools:—in physics, Mr. W. C. D. Whetham; in anatomy, Mr. A. H. Young; in physiology, Mr. Leonard Hill; in pathology, Dr. E. W. Ainley Walker; in forensic medicine, Dr. A. L. Ormerod; in medicine, Dr. J. R. Bradford; in surgery, Mr. H. J. Stiles; in obstetrics, Sir Arthur V. Macan; in preliminary physics, Mr. C. E. Haselfoot; in preliminary chemistry, Mr. A. Angel; in preliminary botany, Prof. J. Reynolds Green.

The Burdett-Coutts scholarship for 1905 has been awarded to Mr. James A. Douglas, Keble College.

The Junior Scientific Club held its 276th meeting in the museum on November 8. Prof. Gotch exhibited the Gotch ophthalmic spinthariscope, and Dr. H. M. Vernon read a paper on the chemical constitution of protoplasm.

CAMBRIDGE.—The election of the well known scholar Mr. F. C. Burkitt, of Trinity College, to the Norrisian chair of divinity has a certain interest outside theological circles. It is, we believe, the first time that a layman has been elected to a chair of theology in the University of Cambridge. The Norrisian chair is open to laymen, but until this year has invariably been held by clergymen. That the heads of houses, who form the electing body, should have made this departure is perhaps a sign of the times.

Mr. C. T. R. Wilson, Sidney Sussex College, has been re-appointed demonstrator of experimental physics for a period of five years from Michaelmas, 1905.

On Monday, November 6, the following were elected to vacant fellowships at St. John's College:—Mr. J. W. H. Atkins, lecturer in English at the Victoria University, Manchester, and Mr. Frank Horton, for research in physics, 1903, Allen student, 1904; D.Sc. London and Mackinnon student of the Royal Society. Mr. Horton joined the university as an advanced student.

IN connection with Sir Donald Currie's offer of 20,000*l.* to Queen's College, Belfast, on condition that a similar sum is raised by those interested in the welfare of the college, President Hamilton announced on November 11 that subscriptions forthcoming to that date amount to nearly 16,000*l.* The remainder of the sum must be subscribed, according to Sir Donald Currie's conditions, before Christmas.

WE learn from *Science* that Mr. Andrew Carnegie has offered 20,000*l.* to Union College, for an engineering building, on condition that the institution raises a like amount for this purpose. Mr. Carnegie has also offered to give Smith College one-half of 25,000*l.* required for a biological laboratory. It is worthy of note that the first of the initial group of seven structures that form the new Carnegie Technical Schools, in Pittsburg, Pennsylvania, has been opened with a class of 120 students, selected from more than 600 applicants.

THE Department of Agriculture and Technical Instruction for Ireland will award in July, 1906, not more than ten open scholarships and ten limited scholarships to assist students of domestic economy to undertake the full course of instruction at the Irish Training School of Domestic Economy, Dublin. Scholarships will entitle the holders to free admission to the full course of training. The school is not residential, and no subsistence allowance is given. The scholarships will be awarded as the result of a competitive examination. Forms of application may be obtained from the secretary of the department after January 1, 1906.

A *Times* correspondent reports that the trustees of the Witwatersrand Council of Education have decided to dispose of a sum of 115,000*l.*, raised in 1899 to provide elementary education for the Uitlander community, in the following manner. The Transvaal Technical Institute is to receive 60,000*l.*, and 30,000*l.* is to be used to found a public school at Frankenwald on the lines of an English public school. The remaining 25,000*l.* will probably be divided between Jeppestown High School and Johannesburg College, but is held over until the publication of the report of the Government Commission on Secondary Education.

IT is announced that a school for post-graduate medical study, to be named "The London School of Clinical Medicine," is to be established by the Seamen's Hospital Society at the *Dreadnought* Seamen's Hospital, Greenwich. The hospital contains 250 beds, and by the addition of eminent members of the medical profession to the present staff, and by an affiliation for teaching purposes with other special hospitals south of the Thames, it is hoped that a complete curriculum for post-graduate study may be arranged. The new school will be complemental to the same society's School of Tropical Medicine at the Albert Dock, which has proved such a success.

AT the session of council of University College, London, on November 6, the following resolution was adopted and ordered to be communicated to Mr. Bawden and Mr. Speyer:—"That the most grateful thanks of the council be offered to Mr. E. G. Bawden and Mr. Edgar Speyer for providing and allotting the sum of 16,000*l.*—to be known as 'the Bawden Fund'—to the fund for advanced university education and research, thereby making up the balance of the sum of 200,000*l.* necessary to complete the financial arrangements for the incorporation of the college in the university. The council are of opinion that by promoting the incorporation of the college in the university they can most effectually realise the purposes for which the college was founded and can best advance the cause of learning and science. They therefore feel that they can congratulate Mr. Bawden and Mr. Speyer on helping to complete an arrangement that is likely to have a far-reaching influence in the furtherance of advanced education and research in London."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, July 20.—"The Influence of Phase Changes on the Tenacity of Ductile Metals at the Ordinary Temperature and at the Boiling Point of Liquid Air." By G. T. **Beilby** and H. N. **Beilby**, B.Sc. Communicated by Prof. J. Larmor, Sec.R.S.

The observations recorded in this paper are intended to prepare the way for a more direct attack on the problems of molecular cohesion by the establishment of clearer views as to the influence of changes of phase on the tenacity of ductile metals at various temperatures.

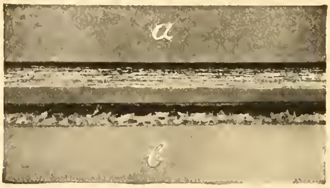

Fig. 1.

Fig.

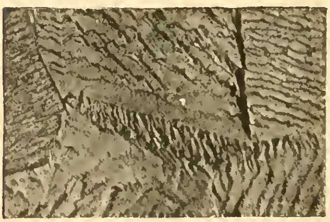

Fig.

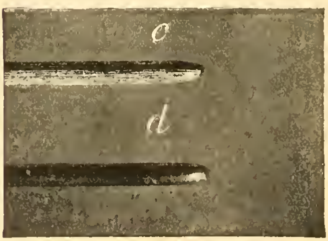

Fig. 4.

According to the phase theory of the hard and soft states in metals which was first developed by one of the authors more than a year ago, the changes of state from hard to soft and from soft to hard were shown to be due to the changes of phase brought about, in the one case by heat, and in the other by mechanical deformation or flow. In the ductile metals the crystalline is the mechanically unstable phase, while the amorphous only becomes thermally unstable when a definite temperature is reached.

The comparative mechanical instability of the two phases is well illustrated in the stretching of wires under tension. Annealed wires, which are in the **C** phase, stretch when they are stressed beyond the yield point; hardened wires, which are partly in the **A** phase, do not stretch—they break without extension when their limit of tenacity is reached.

The homogeneous **C** phase in ductile metals has no true breaking point—it yields and stretches when stressed beyond the elastic limit, and in so doing it passes partly into the **A** phase, and rupture occurs at the breaking point *of the mixed structure*. The tenacity of the mixed structure approaches, but never quite reaches, that of the homogeneous **A** phase. For the purpose the authors had in view it was necessary to obtain the metals as nearly as possible in this homogeneous condition.

Wire drawing was the means employed for the breaking down of the **C** phase. After a wire had been stretched to four or five times its original length by drawing it through the holes of a wire plate, all the ordinary traces of crystalline structure disappeared, but it still consisted of minute granules of the **C** phase embedded in a matrix of the **A** phase. Further drawing at the same temperature alters the mixed structure only slightly; for each temperature there appears to be a certain mechanical equilibrium between the phases. By lowering the temperature of drawing, the **C** phase is further broken down into still smaller granules, and the mixture approaches more nearly to the homogeneous **A** state.

(*a*) Fig. 1 is a photograph of a gold wire which has been etched after drawing. The flow lines near the surface consist of rows of granules. (*b*) On the same photograph, shows the effect of heating another piece of the same wire to about 400°. Removal of the surface by etching now discloses the fully developed crystalline grains with their differently oriented lamellæ. The thermal transformation from **A** to **C** has taken place, and the wire is restored to the soft condition. Figs. 2 and 3 are photomicrographs at higher magnifications, which show the details of structure more fully. Fig. 2 is the granular structure by oblique light at a magnification of 250, and Fig. 3 is the crystalline structure by normal light at a magnification of 700.

The observations were made on wires which had been as completely as possible converted into the **A** phase by wire drawing at the ordinary temperature, and in every case the tenacity observed was higher than any which had been recorded by previous observers for equally pure metals.

	Tons per square inch
Gold. Purity—9,997 per 10,000	
Tenacity at 288° absolute (15° C.)	15·6
,, 53° ,, (−180° C.) ..	22·4
Silver. Purity—10,000 per 10,000	
Tenacity at 288° absolute (15° C.)	25·7
,, 53° ,, (−180° C.) ..	34·4
Copper. Purity—9,996 per 10,000	
Tenacity at 288° absolute (15° C.)	28·4
,, 53° ,, (−180° C.) ...	36·0

The wires broken at the ordinary temperature showed no general stretching. There was a slight extension of from ½ per cent. to 1 per cent., due entirely to a sharp reduction of diameter at the actual point of rupture. At the boiling point of liquid air all the wires stretched from 11 per cent. to 12 per cent. This stretching was uniform over the whole length between the grips. This was confirmed by exact measurements of the diameter at a number of points.

The appearance of the fractured ends revealed several points of interest. In every case the copper wires showed the cupped formation at the extreme end. This formation is evidently due to the lower tenacity of the central core, due to the presence of gas bubbles which have been drawn out into long tubes or cells. The silver wires occasionally showed a slight cupped formation, but in this case the gas bubbles to which it was due were globular, as if they had been evolved at the moment of fracture. The gold wires were practically free from sponginess, and the fractures were almost perfectly viscous (Fig. 4).

By drawing wires at the lowest possible temperatures the authors hope to obtain the ductile metals in their condition of maximum tenacity, and from the figures then

available to be able to calculate the molecular cohesion at the absolute zero.

July 29.—"Studies on Enzyme Action. VIII.—The Mechanism of Fermentation." By E. Frankland **Armstrong.** Communicated by Prof. H. E. Armstrong.

The experiments described, which were begun in the Carlsberg Laboratory, Copenhagen, were undertaken to ascertain, if possible, the manner in which the activity of the various organisms giving rise to alcoholic fermentation is dependent on, or influenced by, the enzymes which they contain. The action of twenty selected yeasts on each of the four hexose sugars glucose, fructose, mannose and galactose, and on the disaccharides cane sugar, maltose and milk sugar, was investigated. All the yeasts tested were able to ferment glucose, mannose and fructose, but quite a number were unable to ferment galactose. It is shown that inability to ferment galactose has nothing to do with the absence from the yeast of any one of the sucroclastic enzymes, since yeasts are to be found which are without action on galactose; in fact, the fermentation of glucose and galactose is brought about by different mechanisms.

The results further indicate that the power of a yeast to ferment mannose, glucose or fructose is clearly in no way conditioned by the presence of a particular sucroclastic enzyme; indeed, it would seem that the occurrence of alcoholic fermentation is altogether independent of the presence of an enzyme—whether free or fixed—able to induce the hydrolysis either of maltose or of sucrose.

The fact that the three hexoses which behave alike have one common enolic form is of utmost significance as an indication that the formation of the enol is the initial stage in the fermentation of the hexose, and that the breakdown of the molecule commences at the terminal carbon atom.

Chemical Society, November 2.—Prof. R. Meldola, F.R.S., president, in the chair.—Molecular conductivity of water: P. **Blackman.**—The stereoisomerism of substituted ammonium compounds: H. O. **Jones.** Wedekind's supposed β-phenylbenzylmethylallylammonium iodide is proved to be in reality *phenylbenzyldimethylammonium iodide.* At present optical activity is the only evidence of stereoisomerism of quinquevalent nitrogen compounds of the type Nabcd,X, and the hypothesis suggested by the author (*Trans. Chem. Soc.,* 1903, lxxxiii., 1403), slightly developed, is adequate to explain all the known facts.—Note on the fluorides of selenium and tellurium: E. B. R. **Prideaux.** The fluorides of selenium and tellurium are gaseous substances, easily condensable by cold, forming white, snow-like solids. They have the formulæ SeF_6 and TeF_6.—The constitution of glutaconic acid: J. F. **Thorpe.**
Some alkyl derivatives of glutaconic acid and of 2:6-dioxypyridine: H. **Rogerson** and J. F. **Thorpe.**—Note on the formation of β-methylglutaconic acid and of αβ-dimethylglutaconic acid: F. V. **Darbishire** and J. F. **Thorpe.**—The influence of water and alcohols on the boiling point of esters. A modification of Markownikoff's method of preparation: J. **Wade.** The Markownikoff interaction proves on investigation to proceed in most cases readily at 100°, and in presence of any strong acid; it may be modified to afford a general and practically automatic method of preparing the lower alkyl esters of such acids as formic, acetic, propionic, and butyric.—Note on bromine fluoride: E. B. R. **Prideaux.** Fluorine when passed over bromine combines with it to form a pale yellow liquid, which freezes to a white solid, melting at −2°, and which probably has the formula BrF_3.—Solution and pseudo-solution: E. **Linder** and H. **Picton.** The authors discuss (1) the physical and chemical properties of colloidal arsenious sulphide; (2) the physical and chemical properties of colloidal ferric hydroxide; (3) dyeing, a phase of coagulation.—The influence of very strong electromagnetic fields on the spark spectra of ruthenium, rhodium, and palladium: J. E. **Purvis.** The general results showed that (1) most of the lines are divided into triplets, and that there is a periodic or rhythmic change in the direction of the vibrations of the constituents of the triplets; (2) some lines become quadruplets, and within certain definite regions of the spectrum their constituents also change the directions of their vibrations; (3) other lines become doublets; (4) the inner member of the triplets is usually the strongest; (5) the strongest spectral lines are not the most widely separated when vibrating in the field; and (6) the decrease in the width of the triplets does not proceed *pari passu* from the less to the more refrangible end of the spectrum.—A volumetric method of estimating the cinchona alkaloids by means of their double thiocyanates: P. W. **Robertson.** Notwithstanding the complexity of double salts of this type, the determination of the amount of thiocyanate removed from solution by the alkaloids forms an accurate and speedy volumetric method of estimating quinine in the commercial drugs and in the assay of the crude cinchona bark.—The osmotic pressure of sugar solutions in mixtures of alcohol and water: P. S. **Barlow.**

Mathematical Society, November 9.—Prof. A. R. Forsyth, president, in the chair.—The De Morgan medal was presented to Dr. H. F. Baker.—On improper double integrals and On the arithmetic continuum: Dr. **Hobson.** In the first of these papers necessary and sufficient conditions are obtained in order that a double integral, of which the integrand becomes infinite at an infinite number of points within the domain of integration, can be transformed into a repeated integral, so as to be capable of being evaluated by successive integrations with respect to two variables. The second paper deals with some criticisms by J. König levelled against the fundamental notions of the theory of sets of points and with the possibility of a general construction of all irrational numbers. It is shown how a general definition of all numbers rational or irrational can be obtained, and that the set of numbers constructed by means of the definition has the essential properties of the continuum, that is to say, it is at once "perfect" and "connected."—On the arithmetical nature of the coefficients in a group of linear substitutions of finite order (second paper): Prof. W. **Burnside.** An irreducible group of linear substitutions being given in any one of its possible forms, it may be possible to choose new variables so that, when expressed in terms of them, the coefficients of the substitutions belong to an assigned domain of rationality. The simplest domain of rationality for which this could be possible is that defined by the characteristics of the group. It is shown that, in general, apart from certain exceptional cases, it is possible to exhibit the group so that the coefficients belong to the domain of rationality defined by the characteristics. The result is obtained without introducing the theory of the reduction of the group when regarded as a permutation-group.—The continuum and the second number-class: G. H. **Hardy.** The paper is a reply to a criticism by Dr. Hobson of a construction for certain transfinite numbers given by the author in the *Quarterly Journal of Mathematics,* vol. xxxv.—On the asymptotic value of a type of finite series: J. W. **Nicholson.**—On an extension of Dirichlet's integral: Prof. T. J. I'A. **Bromwich.**

Paris.

Academy of Sciences, November 6.—M. Troost in the chair.—On the mixed derivatives of dextrorotatory camphoric acid and on β-campholide: A. **Haller** and G. **Blanc.** The esterification of camphoric acid by methyl alcohol and hydrochloric acid gives poor yields, the acid ester being produced in considerable quantity. By treatment with phosphorus trichloride, the latter forms the corresponding chloride, from which the neutral ester can be quantitatively obtained by treatment with methyl alcohol. The compounds obtained by the action of ammonia and phenylhydrazine upon the chloride are also described, and the preparation of the β-campholide by the reduction of the neutral methyl ester with sodium. The yields of the latter ester are poor, and the attempt to prepare from it an isomeric cyanocampholic acid was not successful.—The evolution of the Tertiary mammals: the importance of migrations: Ch. **Depéret.** The author emphasises the importance of an exact study of the migrations of mammals at different periods in order to explain the appearance of a given group in strata not containing their immediate predecessors, and gives details for the Eocene fauna.—On recurrent convergent relations: Pierre **Boutroux.**—On a certain category of functions: H. **Padé.**—On the impossibility of negative impulse waves in gases: Győző **Zemplén.** An impulse wave is a surface propagated in a

gas the density and velocity of which undergo abrupt variations. Such a wave is not purely adiabatic, even when the gas is isolated from all sources of external heat. In the case of a positive wave the gas itself is a source of heat, and the entropy of the system increases; the inverse case is not possible.—Remarks on the preceding note: M. **Hadamard.** Researches on gravitation: V. **Crémieu.** It is shown that it is possible to repeat the Cavendish experiment in liquids under conditions equal, if not superior, to those realised in air.—On the electrical conductivity of selenium: Maurice **Coste.** The selenium in these experiments was placed between gold plates 1 mm. apart. The gold has the advantage over other metals of not forming a selenide, the conductivity of which might interfere with the accuracy of the results. If the selenium is rapidly cooled, the resistance is above 50 megohms, but after annealing it falls to some thousand ohms. It has been found that to obtain a selenium that is very sensitive to the action of light it is necessary to have it in the metallic state in a form as compact as possible.—The determination of calorific conductivity: J. **Thovert.**—The ultra-violet spectra of the purins: Ch. **Dhéré.** Thirteen photographs were made on the same plate, the first being the comparison spectrum, the others the absorption spectra of the aqueous solution of the purin considered with progressively increasing thickness. Results are given for 6-oxypurin, xanthin, and uric acid.—On the reduction of oxides and on a new method of preparation of the compound $SiMn_2$ by means of aluminium: Em. **Vigouroux.**—Molecular transpositions and the migration of carboxyl in the dehydration of certain acid-alcohols: E. E. **Blaise** and A. **Courtot.** The ethyl ester of ββ-dimethyl-β-phenylhydracrylic acid, under the influence of phosphoric anhydride, gives dimethylatropic acid. The removal of water in this reaction must have been preceded by the migration of the carboxyl group, and furnishes the first example of such a migration.—On the crystallography of a double compound of ammonium chloride and nickel bromide: Fréd. **Wallerant.**—Rheotropism of some hydroids: Paul **Hallez.**—Experiments on the toxicity of eggs: Gustave **Loisel.** The yolks of the eggs of the chicken, duck, and tortoise contain substances which, when injected into the veins, under the skin, or in the general cavity of the body, determine promptly the death of the injected animals.—Contribution to the study of Corti's organ: M. **Marage.**—On the nature of the pigments of the blood: MM. **Piettre** and **Vila.** The author has repeated Nencki's work on the composition of Teichmann's crystals, and obtains analytical results for the substance which vary with varying conditions of preparation, and hence concludes that the formula attributed to the substance is illusory.—Researches on the fatty acids. Experimental lesions: Jean **Camus** and Ph. **Pagniez.** On the age of the Vire granite: A. **Bigot.**—On the parallelism of the Upper Eocene strata of Biarritz and Vincentin: Jean **Boussac.** On the storm of July 4 in the district of Orleans: M. **Maillard.**

ZOOLOGY OF THE VERTEBRATA.

A Student's Text-book of Zoology. By Adam Sedgwick, M.A., F.R.S. Vol. ii. Pp. xv+705; illustrated. (London: Swan Sonnenschein and Co., Ltd.; New York: The Macmillan Company, 1905.) Price 21s.

THE first volume of this "Student's Text-book of Zoology" was published in 1898, and dealt with the invertebrate animals except echinoderms and arthropods. It was then hoped that another volume would suffice to complete the book, but that sanguine estimate was far off the mark. After half a dozen years the second volume has been completed, thicker than the first by a hundred pages, and the echinoderms, arthropods, enteropneusts, and tunicates are still to follow. A fourth volume will be required to deal with the principles of zoology. By that time the so-called student's text-book will require another title.

The first volume has a well deserved reputation for accuracy, clearness, terseness, and independence, and in the crowd of text-books it has filled a definite place to the satisfaction of teachers as well as of students. Presupposing a knowledge of "types," it dealt with the various classes in a systematic way, giving detailed classifications and taking account of a very large number of important forms. It was a successor of Claus's "Lehrbuch," but stronger in its grip, and vastly more interesting. The second volume is like unto the first, and it has been worth waiting for.

After a short introduction on Chordata, the author deals with the lancelets; then follows a discussion of the general characters of Craniata, and so on through the vertebrate series, each class, subclass, and order having its definition and general exposition followed by small print dealing with families and genera. The definitions are models of terseness; the large-print discussions of general characters are marvels of condensation and selective insight—almost peptonised extract of zoology—and the small print is monumental in its erudition. We took the last four vertebrates that happened to come into the laboratory—a water-shrew, a golden-crested wren, some young fierasfers, a specimen of Palæospondylus—and for three out of this fortuitous four we found interesting information in this encyclopædic volume. There is, however, another side to this relative exhaustiveness, that the details of classification are apt to change rapidly, and that many of the implied systematic conclusions must, from the nature of the case, have been simply accepted by the author because they were well vouched for by specialists. But there does not seem to be any way out of this except refraining from the very detailed treatment which is part of the characteristic aim of the book, or else adopting the cooperative device, which is apt to mean a lack of unity. It says much for the energy of the author that the classification of teleostean fishes is substantially that worked out by Mr. Boulenger, who supplied proofs of his work before its publication.

Leaving the question of the desirability of attempting so great exhaustiveness in what is at least called a student's text-book—a question which the gratefully recognised utility of the first volume has in part at least answered—we venture to express the hope that the final edition of the whole work will see some re-arrangement. Even unconsciously the student has what Herbert Spencer called an "architectonic" instinct; he likes some semblance of evolutionary order in his text-book. But although Mr. Sedgwick allows that enteropneusts and tunicates are chordates, they are not discussed in this volume, but must eventually be treated, we presume, at a remote distance, remote even from Amphioxus. Similarly, the annelids will be far away from the arthropods, and other instances might be given which suggest that the conditions of the production of this great work have not favoured its architectural plan.

Another carping criticism which we must make is this, that whereas the preface, like so many other prefaces, holds out the promise of "dealing fairly" with *habits* as well as with morphological aspects, we find after all that we have to be grateful for small mercies.

We confess also to some disappointment at the severity of Mr. Sedgwick's scientific mood, which may be illustrated, for instance, by this sentence:—

"As to its (the group Mammalia) origin in evolution we have nothing to say for the very good reason that there are no facts by which we can arrive at any conclusion on the subject."

(This does not, of course, refer to the affinities between Mammalia and other classes of vertebrates, which are briefly discussed.) Similarly, it is very difficult to discover what positive view, if any, the author holds in regard to the affiliation of Chordata to an antecedent stock. Incidentally, the author lifts just a little the veil with which he so successfully conceals his evolutionist convictions. Thus he says of the hag-fish:—

"To hold that a free-living animal, and a myxinoid must after all be regarded as such, can lose its eyes through disuse would seem to be an impossible position."

With such useful things to say the author might, to the advantage of his readers, have lifted the veil rather oftener. Criticisms like that of the story of the pedigree of horses are refreshing and salutary, and we regret to learn from the preface that the author has deleted a number of them. We look forward to the fourth volume to reveal more fully the author's scepticism "as to the value of some hypotheses widely held as to the course of organic evolution." It need hardly be said that Mr. Sedgwick is "a convinced evolutionist"; he also believes in the importance of natural selection, even in regard to non-living things; but "as to the origin of the manifold properties of living matter we know nothing. The Darwinian theory did not account for properties; it left their origin to an imperfectly understood interaction between the organism and the environment, and further than this we cannot at present go."

In referring to the construction which must follow criticism, Mr. Sedgwick says:—

"That is the task of the great band of workers in many departments of Biology, who, undeterred by failure and urged on by the fire, enthusiasm, and generous aspirations of youth, return time after time, generation after generation, to the assault of the fortresses of nature well knowing that their material reward will be small, that defeat means the world's neglect and that success, except the greatest, brings but a pittance of its esteem. To them I inscribe this book in the hope that it may serve if only to a small extent to smooth over the difficulties of part of the road which at first they have to travel."

We may be allowed to thank the author for doing more than "smooth over" the difficulties of the road on which all students of zoology have to travel, for he has cleared away many hindrances and pointed out many pitfalls. It would serve little purpose, however, to enter into any discussion of the numerous morphological problems in regard to which Mr. Sedgwick has made some personal and luminous contribution. We feel that we have not said enough in regard to the excellence of his workmanship, but praise of what is masterly is gratuitous. The book's scholarliness, clearness, and carefulness of statement are obvious, but those who work with it will discover other virtues—a suggestive scepticism, a mature judgment, and a more indefinable quality which we can only hint at in the phrase "morphological insight."

AN ESSAY IN HISTORICAL CHEMISTRY.

The Study of Chemical Composition: an Account of its Method and Historical Development. By Ida Freund. Pp. xvi+650. (Cambridge: The University Press.)

MISS FREUND is to be congratulated on having written a very interesting book. It is true that her subject-matter is to be found in many other quarters; she has really written a historical treatise on what is generally called stoichiometry; but having chosen as her title "The Study of Chemical Composition," she has left herself, so to speak, unfettered, and has been able to write somewhat more discursively than if she had compiled a treatise. Indeed, in the preface to the work she confesses:—

"Although anxious to trace separately the *historical development* in the discovery and in the establishment of certain laws and classes of phenomena, I have made no attempt to produce anything sufficiently complete or even sufficiently proportioned to deserve the name of *history*. I have preferred to deal in greater detail with a few researches, especially such as I could repeatedly utilise from various points of view, than to treat a greater number more cursorily, believing in what Lavoisier said more than a century ago that 'in such matters as these, the choice of proofs is more important than their number.'"

The result is a fairly full, indeed in some instances a very full, account of classical researches in the sphere to which she has confined her attention; the only omission is that of all reference to the laws of dilute solutions, and in this she was guided by the fact that the subject has been recently fully treated in many works which are easily accessible.

Beginning with a sketch of the method of the inductive sciences, quotations from Bacon, Jevons, Kant, Whewell, and Mill are introduced, with illustrations of deductive reasoning by Kepler, Lavoisier, Davy and others, having as its basis classification, generalisation, and law. Next follows a fairly detailed study of the phlogistic theory, giving an excellent summary of the views held by the phlogistonists. Here Cavendish's reasons for his choice of the terminology of the phlogistic theory might with advantage have been inserted. Examples of Lavoisier's and Stas's work, and of Morley's synthesis of water are given to illustrate the basis on which the doctrine of the "conservation of mass" is founded. But laws may be of two kinds, exact and approximate; the difference is illustrated by Boyle's law and van der Waals's improved form. We do not notice, however, the remark that van der Waals's formula itself is only a rough approximation to the expression of the behaviour of gases under high pressures. Landolt's experiments, which may be now accepted as a proof of the accuracy of the constancy of mass, are cited; the reviewer does not know if Landolt has published the fact that his doubts disappeared only after he had used silica instead of glass vessels.

Affinity is the subject of the next historical sketch; here the views of Bergmann and Berthollet are very well summarised; and this naturally leads to the conception of fixed ratios by Proust, and the succeeding work of Dalton and Berzelius, with reference to the ideas contended for by Laurent.

The author now harks back to theories of matter, taking up the subject at its earliest start in India and Greece. The speculations of Bacon, Descartes, Gassendi, and Boyle are described, generally in their own words. Next follows a full account of Dalton's atomic hypothesis, of Gay-Lussac's law of volumes, and of Avogadro's generalisation. Berzelius's attitude towards the rival views is explained, and a clear account is given of the veteran Cannizzaro's successful attempt to obtain full recognition of the justice of Avogadro's views, so long overlooked. The determination of atomic weight by means of specific heat, and an excellent account of Mitscherlich's work and its latest development by Retgers (this last, so far as the reviewer knows, has not previously been accessible except in original papers), complete this part of the subject. The periodic arrangement of the elements, and its bearing on the determination of atomic weights, leads naturally to a consideration of the doctrine of valency, and Miss Freund has not omitted to state the attempts which have been made to represent valency in terms of the electronic theory. A chapter on isomerism follows, and the concluding chapter treats of the constitution of matter and the genesis of the elements.

From this sketch it will be seen that Miss Freund has brought together, in a compact form, a great deal of interesting matter. She has quoted freely from the authors whose views she presents, and, on

the whole, with great judgment. The work is professedly a compilation, but it is a compilation by one who knows the subject. It would perhaps have been too much to expect that independent opinion on the many matters discussed should have been expressed, but we are at least put in possession of many views in an interesting and readable form. The work should be read by all advanced students of chemistry.

W. R.

THE KEW INDEX OF FLOWERING PLANTS.

Index Kewensis Plantarum Phanerogamarum; Supplementum Secundum, nomina et synonyma omnium generum et specierum ab initio anni MDCCCXCVI usque ad finem anni MDCCCC complectens. Ductu et consilio W. T. Thiselton-Dyer confecerunt herbarii horti regii botanici Kewensis curatores. Leucocoryne–Zygostates et emendanda addenda. Pp. 105–204. (Oxford: Clarendon Press, 1905.) Price *12s.* net.

THE second and concluding part of supplement ii. of the "Index Kewensis" follows quickly on the first. This means that we now have a list of the names and synonyms of genera and species of flowering plants published from the foundation of binominal nomenclature to the end of 1900—complete except for a serious gap in supplement i. representing the last third of the alphabet for the years 1886–1895. Three parts of the first supplement appeared between September, 1901, and November, 1903; the fourth is therefore much overdue. Its delay is the more to be regretted as the period with which it is concerned was one of considerable activity in systematic botany, including, for example, the great development of the Berlin school under Dr. Engler's direction. It is to be hoped that the completion of this portion of the work, for which Kew is not responsible, will soon be announced.

The best way to appreciate the Kew index is to call to mind the time before its appearance, when getting at the origin of a name meant often a long book-hunt, and sometimes a remarkable revelation of the wonderful and remote places in which it was possible to publish names, such, for instance, as the Melbourne *Chemist and Druggist*, in which, if we remember rightly, some species were published by the late Baron von Mueller. These literary researches were often extremely interesting, but they were not botany, and a failure by some botanists to realise their importance often caused worry and inconvenience to subsequent workers. In passing, we may note a feature of the index to which reference was made at the conference on nomenclature at Vienna last June. It was pointed out that the list of names of genera which a large majority of members agreed must be retained, even though they were not the earliest published names, departed very little from the names recognised in the index—it might even have been possible to have taken the index as a starting point.

The present number makes quite interesting reading, for it marks in a striking way the progress of systematic botany during the five years under consideration. Africa, especially tropical Africa, has afforded much material for work, as evidenced by parts of the Kew Floras, the catalogue of Dr. Welwitsch's Angolan plants, and other publications in this country; and the numerous papers on African botany issued from Berlin. The completion of the "Flora of British India" is chronicled by numerous citations in various genera of grasses; and there is also ample indication of the activity of North American botanists in working out their flora. Here and there is evidence of an important monograph, as that of Bromeliaceæ by Dr. Mez, or of Monimiaceæ by Miss Perkins, in a list of new species, combinations or reductions. Some entries under a quaint or unfamiliar name form a record of antiquarian research and love of priority; such, for instance, are those under Sitanion, a name of Rafinesque which antedates the well known Elymus; these names are promptly reduced to synonymy. It is, however, not always so easy to follow the reductions. For instance, American botanists seem generally agreed that Lewisia, a genus founded by Pursh, must be restored for certain species of Calandrinia; but the index quotes them only as synonyms, referring them back to Calandrinia. In looking down the columns one is struck by the large number of personal species-names, which seems to indicate a want of imagination on the part of some authors; thus nineteen out of forty-two new species of Polygala, and thirteen of twenty-two of Lissochilus, have names recalling the person who first collected or was in some way or other associated with the plant. A few omissions might be noted, though that has probably been done already by those concerned. A curious citation is given, under Peperomia and Panicum, of two species from Dr. Andrews's Christmas Island monograph.

In conclusion, we would express the hope that the record of the next five years, now nearly ended, may be available at as short an interval as possible.

A. B. R.

OUR BOOK SHELF.

Sugar and the Sugar Cane. By Noël Deerr. Pp. viii+395+xix. (Altrincham: Norman Rodger, 1905.) Price *7s. 6d.* net.

So many effects have already been ascribed by politicians and journalists to the Brussels Sugar Convention, that one hesitates to add to its account the recent large output of sugar-cane literature in this country, but there can be little doubt that the brighter prospects which the Convention seemed to promise sugar-cane planters has encouraged publication on this subject, and hence the issue, within the comparatively short space of three years, of four books, in English, dealing with the cultivation of the sugar cane or of the production of sugar therefrom.

There was, of course, much leeway to make up, since the interesting and important results achieved during recent years as the result of the cultural experiments carried on in British Guiana, the West Indies, Mauritius, Hawaii, Java, Queensland, India, and elsewhere were for the most part only available in the uninviting form of Government reports, and similarly there existed no general and concise account of the improvements recently brought about in the machinery used in sugar factories.

Mr. Deerr sets out with the object of "presenting in one consecutive whole a general view of the cane sugar industry," and it may be said at once that he achieves this object fairly successfully.

The arrangement of the volume coincides with the sequence of operations in the production of sugar, the earlier chapters dealing with such subjects as cane varieties, cultivation, influence of soil and climate, manuring and so on, and the later chapters with the harvesting of the cane, its transport to the factory, the extraction of the sugar, processes for the preparation of the commercial varieties of sugar, the disposal of molasses, the analysis of sugar products, and so on.

The objection might be made that some of these later chapters, notably those relating to the use of the polariscope, the estimation of "glucose," and the analysis of sugar-cane products are not sufficiently detailed to enable a novice to carry out the operations described, and yet are so full as to be tedious to anyone merely desirous of grasping the general principles upon which the processes are based.

The book will, however, be found useful by planters and sugar-estate managers who desire to be *au courant* with the progress made on the scientific side of their industry.

The volume is well illustrated—in this connection particular mention may be made of the coloured plates showing stems of some of the principal varieties of cane—and the text is remarkably free from errors, which is perhaps to be attributed to the fact that the book "was seen through the press" by the publisher, Mr. Norman Rodger.

My Strange Pets, and other Memories of Country Life. By R. Bell. Pp. vi+308. (Edinburgh: Blackwood and Sons, 1905.) Price 6s.

"IT is well known that the emu is a native of Australia, where on its vast plains they might have been seen in vast numbers" (p. 2). "The kick of an emu is a serious if not a dangerous one. . . . When sporting they spring up in the air, kicking sideways." Sentences like the above occurring close together at the beginning of a volume, and followed later by others of the same type, make one wonder whether the publishers or their printers keep a proof-reader on their establishments. But grammatical slips of this nature are not the only faults by which the work is disfigured, and the classically educated reader will scarcely fail to experience a severe mental shock when he finds the statement on p. 51 that "'lemur,' in the language of Madagascar, means 'night-wandering ghost.'"

Apart, however, from blemishes, Mr. Bell's book contains much interesting information with regard to the ways of many kinds of foreign creatures—from emus and rheas to jerboas and snakes—in confinement, accompanied by valuable hints as to the best manner of keeping them in health. The author, indeed, claims to have been the first to breed emus in Scotland, and it is perhaps a little characteristic of his nationality to find that the experiment undertaken for amusement turned out a financial success. The subject of foreign "pets" forms, however, only a portion of the volume, and the author records a number of more or less commonplace observations regarding the animals of his own country. As he appears to be an experienced angler, the statement of his disbelief in the theory that fresh-run salmon never habitually feed while in the rivers is worthy the best attention of the officials of the Scotch Salmon-Fishery Commission.

Throughout his life the author appears to have been specially interested in travelling menageries, and in a chapter on this subject he reproduces a long extract from the *Scotsman* of April 10, 1872, describing the sale of Wombwell's menagerie in that year. In this extract Wombwell is stated to have purchased the first rhinoceros and the first pair of giraffes ever imported into this country. As regards the former animal this statement is not strictly true, as witness the Indian rhinoceros described by Dr. Parsons in the early days of the Royal Society. If the statement with regard to giraffes be trustworthy, the fact has been generally overlooked by writers, George the Fourth's giraffe, received in 1827, and the four young animals obtained by the London Zoological Society in 1836, being generally regarded as the earliest importations. Wombwell's giraffes, it is stated, died before they were publicly exhibited. Although containing little that is absolutely new, the book is distinctly readable and entertaining. R. L.

Simple Lessons on Health for the Use of the Young. By Sir Michael Foster, K.C.B., M.P., &c. Pp. vii+114. (London: Macmillan and Co., Ltd.; New York: The Macmillan Company, 1905.) Price 1s.

MANY writers have tried their hands at the production of a small work which shall suitably present to a child's mind those elementary facts of healthy living which, as now generally recognised, should form an essential part of education; but it must be said that hitherto no one has wholly succeeded. Many have failed from an unnecessary elaboration of scientific detail, and others from a faulty presentation of the subject-matter.

Sir Michael Foster's manual makes no pretence at covering the whole of the necessary ground. He makes it clear in the preface that his object is to show how the reasons for *some* of the rules which ought to guide us in the physical conduct of life may be explained even to the very young. The subjects dealt with are:—fresh air, food and drink, light and cleanliness. The physiological basis of certain health principles could not be more happily expressed; but as to how the individual can best meet his hygienic needs in his daily life and circumstance the writer has little—far too little—to say. With this reservation it may be said that Sir Michael Foster's little book is a model of what simple lessons on health to the young should be, and that, as an illustration of how these matters should be presented to young children, it is unequalled by any other book with which we are acquainted. For this reason, if for no other, all those who are likely to have the important duty cast upon them of instructing the young on these vital matters should carefully study its simple, clear, and wholly satisfactory method of treatment.

Actualités scientifiques. By Max de Nansouty. Pp. 365. (Paris: Schleicher Frères, 1905.) Price 3.50 francs.

SUCH a collection of short readings in French as is here provided will prove of service to young students of science who are either learning French or are desirous of keeping up their knowledge of the language by reading which will not take them far from their serious work in science. There are eighty-four popular essays, each of three or four pages, divided into seven groups dealing respectively with physics and chemistry, astronomy and meteorology, electricity and its applications, agriculture, hygiene, psychology and physiology, and applied sciences.

The volume may appeal to a few general readers interested in popular accounts of progress in pure and applied science There are no illustrations.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The British Association and our Colonies.

THAT four hundred members of the British Association have recently visited the principal places of interest in South Africa, that they have been the recipients of magnificent hospitalities, that they have read papers and discussed points of importance bearing upon the development of African colonies, are facts well known to the reading public. Although so much has been written and said about what the association has done, but little has been conjectured as to possible outcomes from this remarkable excursion. To many the expedition may appear as a gigantic "picnic," the members participating in which have had a hurried glance at Africa and have returned with that modicum of knowledge which is proverbially regarded as dangerous. If, however, we turn to a list of the names of those who were members of the association party, and observe that it includes those of recognised leaders in science, literature, and in a variety of professions, casual conclusions of this nature are at once dispelled. What is realised instead is that South Africa has been visited by a number of specialists whose services are frequently retained by Governments and corporate bodies. No doubt these gentlemen have learned much, but it is difficult to imagine that they left South Africa without leaving some small return. Now that they are back in Britain it is tolerably certain that they have brought with them opinions bearing upon railways, mines, agriculture, emigration, and on other matters connected with the development of South Africa, all of which will command attention. A well known eastern country which sends its experts to exploit the western world attains a similar end by systematised departmental methods.

The benefits of greatest importance, however, may be the resultant of personal and friendly relationships which have been established between leading men of science and practical workers in two related countries. These relationships should stimulate reciprocity, remove misconceptions, and pave the way to cooperation in various directions. Regarded from this point of view, it is difficult to escape from the conclusion that the meeting of the British Association in South Africa has played an important part in strengthening a union between a parent and its offspring.

Should views of this description meet favour, it remains for members of the British Association and others to consider the possibility of extending the work of such national importance. One method by which this might be attained would be the organisation of an intercolonial meeting of the British Association. The difficulties connected with the organisation of such a convention, say in London, to be supplemented by visits to various centres in Britain, to which representatives and visitors from oversea connections should be invited, have already been informally discussed by home and colonial members of the British Association. They do not appear to be insuperable, and it may be anticipated that such an undertaking would meet with national approval and support.

JOHN MILNE.

The Stone Age of the Zambesi Valley, and its Relation in Time.

ABOVE and below the Victoria Falls stone implements are present in profusion, both in the river gravels on the highest margins of the Zambesi valley and also spread broadcast, along with rolled gravel, on the basalt platforms of the ancient river channel below the Victoria Falls. Stone implements are also found in abundance along the highest banks of the Zambesi below the present falls, at the junction of the "desert sands" and the underlying basalts. (I use the term "desert sands," for, though its surfaces are now wooded, it has been deposited under Æolian desert conditions.) At the base of these "desert sands," which form the highest margin of the old Zambesi valley below the present falls, and resting immediately on the basalt platform, are horizontal beds of chalcedony, ferruginous sandstone, and quartzite sandstone; these are certainly the products, and have been formed at the base of the "desert sands."

These "desert sands," which occur on both sides of the Zambesi valley, I was able to examine for some distance below the Victoria Falls. They are of considerable thickness, at places fifty, sixty, and perhaps a hundred feet in depth. The railway from the falls to Bulawayo passes through these sands, and good sections are to be met with. There are no stone implements, pebbles, or stone of any description to be found throughout their entire structure until we reach the very bottom, where the horizontal beds of chalcedony, ferruginous sandstone, &c., rest *in situ* on the basalts. The chalcedony layer varies in thickness from a few inches to two feet or more. I may here remark that the majority of the implements are made of chalcedony; likewise to a great extent are the pebbly gravels of the river, both above and below the Victoria Falls. Of the thousands of implements and rolled pebbles that I handled, very few were made of any other substance but the rocks that lie at the base of the "desert sands," and I did not find a single implement made of basalt or dolerite. The quarries of the prehistoric men were the beds that lie at the base of the "desert sands," and when they were fashioning their implements along the horizon of the chalcedony formation there can be no doubt that the Zambesi was flowing at their feet, a smooth and noble stream, precisely as it flows now through the "desert sands" above the present falls, and the basalt and dolerite platforms were sunk under the waters of the river.

The evidences that the river gravels and included implements now resting upon the basalt platforms below the Victoria Falls were deposited by the Zambesi when it flowed at a height of 400 feet or 500 feet above its present level are as follows:—Above the Victoria Falls, on the left bank of the river, near the ferry to Livingstone Island, the river gravels are well in evidence. They consist of rounded pebbles of chalcedony, quartzites, and various other rocks; the contained implements are more or less water-worn, and of the same character as those in the gravels below the Victoria Falls. I took from this horizon implements of Palæolithic type.

When we pass below the Victoria Falls to the Rain Forest, we can realise without doubt that the Zambesi once flowed over this area, and that its southern cliff must once have been the falls of the river. In the water-worn gullies of the Rain Forest implements and rounded pebbles are to be found of the same character as those in the beds above the Victoria Falls; they must have been deposited there by the river when the Rain Forest area formed part of its bed. When we travel further down the course of the old river-bed we find on the platforms and promontories of the basalt, now eroded by deep lateral ravines, which overlook the zigzags of the cañon, where the Zambesi rushes 400 feet below, deposits of implement-bearing gravel. We cannot therefore escape from the conclusion that these implements and pebbles were deposited there by the Zambesi when it flowed over these surfaces prior to the excavation of the chasm. From these surfaces I took implements some of which, if found in Europe, would be called typical Palæolithic types.

If I am correct in my observations as to the method of deposition of these implements, we may be satisfied that an immense period of time has elapsed since Palæolithic man lived on the banks of the Zambesi. We cannot at present measure that period by our chronological record, but we may be satisfied that man lived there when the Zambesi below the Victoria Falls flowed 500 feet above its present level, and before its waters had carved out through hard basaltic beds the wonderful chasm that now extends for forty miles below the Victoria Falls. Perhaps geologists may in the future be able to arrive at some trustworthy conclusions as to the rate of retrocession of the falls of the Zambesi, and the carving out of its chasm, which would give a more or less accurate determination of the period when primæval man occupied the Zambesi valley. At present we can only say that a great lapse of time must have occurred; but this deduction, being based

on recognisable geological factors, namely, the wearing out of the chasm of the Zambesi and the retrocession of its falls, we have an advance in our positive knowledge as to the remote age of the Palæolithic stone implement beds of South Africa. H. W. FEILDEN.

Terminology in Electrophysiology.

TAKING the diagram given by Dr. Fraser Harris (p. 5), all writers will agree with him that A is positive plate and negative pole, and I believe that the use of the word "zincative" has gone some way to promoting this agreement.

Dr. Harris goes on to say that no loophole for confusion could be left if the qualifying words *externally* or *internally* were added, by stating, *e.g.*, that A is internally electropositive to B and externally electronegative to B.

I find three objections to this suggested clarification:—

(1) The expressions thus qualified are cumbrous, and must infallibly become abbreviated in current language by omission of the qualifying words.

(2) The expression "externally electronegative" contradicts the conventional use of the word "electronegative" which is attached to the plate and not to the pole.

(3) There is no provision for the complementary qualification to denote that a tissue is capable of being aroused to electromotive action, *i.e.* capable of being rendered zincative, *i.e.* zincable.

I freely admit that this convenient jargon offends the ear while arousing the understanding. I will gladly bury the words "zincative" and "zincable" when they have fully served their purpose as danger-signals that confusion is possible; but until we have agreed that active tissue shall be called "externally or galvanometrically negative" or "internally electropositive" I do not think loopholes for confusion have been closed. I should be satisfied with the old external word "negative" if it did not involve the conception of an internal "propagation of a wave of negativity," and the occasional misstatement that a wave of electronegativity is propagated through nerve and muscle. I should be glad to say that A is electropositive to B if I were not convinced that the prefix "electro" would be occasionally dropped to the further confusion of the reader accustomed to be told that A was (externally) negative.

So that, *en attendant mieux*, in order that there may be no confusion as to my own meaning that A is externally negative and internally positive, I say that A is like zinc or zincative. The parable, if there be parable, is intended to point out and avoid a confusion, but there appears to be an unfortunate tendency to confuse an indication of confusion with an introduction of confusion.

The physicist does not help us much. When he has appreciated the ambiguity of our physiological language, which is of physical origin, he supposes it to be no more than another case of the ambiguity familiar to us in the naming of accumulator poles, where, in order to avoid the perplexities that would arise from calling the same plate positive during charge and negative during discharge, the convention has become accepted always to call positive the plate that is connected with the positive pole of the charging battery or dynamo.

Our trouble is that there is among physiologists no accepted clear convention analogous with this convenient custom of miscalling the positive plate of an accumulator in a perfectly intelligible manner. Therefore again, when it seems particularly desirable to indicate seat of activity and direction of current internally as well as externally I still say "*zincative*" in order that there may be no mistake of meaning. A. D. WALLER.

BOTH Dr. Harris (p. 5) and Prof. MacDonald (p. 28) somewhat misrepresent the use by physicists of the signs + and −. As applied to a closed circuit they are purely relative, each point being simultaneously positive to all points on one side of it and negative to all those on the other. The confusion arises from the fact that terms belonging properly to electrostatics were adopted long ago in describing the phenomena of the galvanic battery.

It is impossible to define direction in a circle—or any closed circuit—with less than four points—one lying in a different plane from the other three. In a circle drawn on paper, one of these is given, namely, the position of the observer behind or in front of the paper. If we put two others on the circle there is still ambiguity, for we may go from + to − in either direction, as in the armature coils of a dynamo; but with the use of three symbols the ambiguity vanishes. Thus *abc, bca, cab* indicate one direction, and *cba, acb, bac* indicate the other. As with formulæ containing an asymmetric carbon, the enantiomorph is given by turning the diagram over.

In diagrams of electric circuits some portion of the apparatus, either the source of E.M.F. or the place where it is being used, is tacitly taken as the third symbol, and the signs + and − put on either side of it to indicate which way the current flows. Dr. Waller's word "zincative," to anyone who knows how zinc behaves, indicates without possibility of error the direction of the current across the region that generates it, and the electrically-minded student may trace its course thence by arrows, remembering that while the circuit is closed the tail of each arrow is positive to its head, but directly the circuit is broken the whole of the side that ends with a head is positive to the whole of the side that ends with a tail.

To the physicist the terminology formerly used by physiologists was most confusing—in my own case it conveyed an entirely wrong impression until I had made an experiment with my own hands. It is most desirable that the anomaly should be removed, and in my opinion it may best be done by dropping the unsuitable terms positive and negative, and saying either that current flows from the more active to the less active part of a tissue or that the one is zincative to the other. GEORGE J. BURCH.

University College, Reading, November 11.

Action of Radium Salts on Gelatin.

ON continuing the experiments detailed in NATURE of October 26, I found that lead and strontium salts produced the same results upon gelatin as was the case with radium, but the strontium "growths" were much less vigorous than the others.

On considering the results, it is seen that the metals named are those which form insoluble sulphates, and it occurred to the writer that the "growths" were simply a precipitate of some insoluble body formed by the action of the salts used upon the gelatin.

Various solutions of bouillon and gelatin were prepared, and to each were added a few drops of solution of radium or barium or lead salts, with the result that in each case a precipitate was obtained which on careful examination was found to consist of a sulphate, or at all events an insoluble compound, containing sulphur.

The precipitate produced by the radium salt was tested to see whether it was in any way different from that produced by the barium salt, but, with the exception that it was radio-active, it appeared to be similar in all respects. It was insoluble in strong acids, and gave a sulphide on fusion with sodium carbonate on charcoal, and qualitatively contained no other metal than barium.

In making the experiments, a few drops of the gelatin were placed on a glass slide, and particles of radium and barium salts added as described in the last communication. The "growths" appeared. Some solution of barium nitrate or radium salt was now added to the liquefied jelly. The usual precipitate appeared, and this was filtered off through a porous tube. The clear jelly was now tested with radium and other salts, and no growth could be seen even after seven days.

I think this proves very conclusively what the alleged "growths" are, viz. that they are nothing more than finely divided precipitates of insoluble barium salts. I have examined these precipitates with the highest microscopic power at my disposal, and cannot, in any case, perceive that there is anything of the nature of cell division occurring.

Of course, many pairs of particles may be found, but the grouping must be purely fortuitous.

As there is only a limited amount of matter in the gelatin which can be precipitated by the radium, a concentration occurs at the point of contact of the salt with

the gelatin, and then a slow diffusion of the remaining salt takes place downwards, and this might give rise to the idea that the thing was really growing.

W. A. DOUGLAS RUDGE.

Woodbridge School, Suffolk.

The Spectrum of the Positive Rays (Canal-Strahlen).

IN former publications (*Ann. d. Phys.*, vol. xiv., p. 524, 1904; vol. xvi., p. 490, 1905; "Die Elektrizität in Gasen," Leipzig, 1902, pp. 446, 457) I have expressed the opinion that the carrier of the line spectrum of a chemical element is the positive atom-ion, while, on the other hand, the band spectrum is due to the re-combination of positive atom-ions with negative electrons. From this it would follow that the particles of the positive rays (being positive atom-ions) should emit the line spectrum of the gas in which they are produced. Moreover, since these particles possess a considerable velocity, their spectrum lines, observed in the direction of the rays, should have a position and breadth differing from the position and breadth when the lines are observed in a direction normal to the rays. Again, since the positive rays ionise the gas traversed by them, re-combination of positive and negative ions must take place in their path; the gas traversed by the positive rays must therefore emit the band spectrum, which will be superposed on the line spectrum due to the positive rays themselves. The lines of the band spectrum must have the same position whether they are observed in the direction of the positive rays or in a direction at right angles to them, inasmuch as their carriers do not possess the velocity of the positive rays.

I now state briefly the results of an experimental spectrographic examination of the light emitted by a gas traversed by positive rays. (1) Nitrogen shows simultaneously the band and the line spectrum, hydrogen shows simultaneously the series spectrum ($H\alpha$, $H\beta$, . .) and the many lines spectrum. (2) The line spectrum emitted normally to the positive rays and the line spectrum emitted in the direction of the rays are different; the former shows in hydrogen sharp lines of the known wave-length, while the latter shows these "stationary" lines, and besides them, on their ultra-violet side, new widened lines ("displaced" lines). (3) This displacement is greater when the velocity of the positive rays is greater. (4) The lines of the band spectrum (many lines spectrum) have the same position and breadth whether they are observed in the direction of the positive rays or in a direction at right angles to them. A full account of the investigation will be published shortly.

Göttingen, November 3. J. STARK.

Replicas of Diffraction Gratings.

KINDLY allow me to correct a statement contained in your notice of Mr. R. J. Wallace's replicas of diffraction gratings in your issue of November 2 (vol. lxxiii. p. 21).

It is there stated, as also in the *Astrophysical Journal* from which the extract was taken, that I first flood the grating with oil in my method of producing replicas. This I may say I have never done except when making experiments, my procedure being exactly the same as Mr. Wallace's, viz. to flood the grating direct with the clarified celluloid solution, dry it in much the same way, but using special precautions to ensure perfectly even drying, stripping and mounting in a similar manner to Mr. Wallace, but leaving out the gelatin coating, which in my opinion is quite unnecessary.

I beg to enclose you one of Mr. Wallace's first quality (average) replicas, kindly sent to me by him in exchange for one of my own, as also a couple of mine for comparison. The great difference to be noted in their surfaces and performance is due to the peculiarities in the surfaces of the original gratings, one of my own replicas having a brightness in the first spectrum on one side of at least four times that of the other, and twice that of Mr. Wallace's replica.

The grating from which the very bright replica is taken is a "Rowland" of 14,438 lines to the inch, and was formerly the property of the late Dr. Common. The original of the other is a very beautiful specimen of recent work on the Rowland engine, 15,038 lines to the inch. Now, whilst the latter when mounted on parallel plane glass gives comparatively feeble spectra, when mounted on prisms for direct-vision purposes, and tilting the prism to the angle required for the minimum deviation for the diffraction spectrum, first order, the brightness approaches that from the "Common" grating, whilst its much greater freedom from scattered light renders it very suitable for prominence and similar work, the dispersion being about equal to five 60° flint glass prisms in the centre of the spectrum, and decidedly greater at the red end.

This increase of brightness is, of course, attributable to the form of the grooves, less interference being produced under the latter condition, and this notwithstanding the increase in dispersion.

It may be of interest to some to know that I have succeeded in mounting these grating films on a perfectly flattened ring of glass, so that, by avoiding the use of glass as a base, light of very short wave-length can be examined by this means, either in the one case by transmission to about λ 2600 or by reflection to as low as λ 1850, and possibly lower. (The discovery of this reflective property for ultra-violet light was made by Mr. Morris-Airey, of the Victoria University, last year.) In order to examine by reflection either a partial vacuum is created behind the film when mounted on a glass ring or the film is mounted on a concave surface, which, although not giving the lines of the grating their true form, gives very fair resolution.

I have also succeeded in making concave replicas practically as perfect as plane ones, by rotating the grating during the drying process at such a rate that the paraboloidal curvature of the solution was practically the same as that of the grating. Anyway, the difference is so slight that when dry no rings can be seen on examining it by monochromatic light before the film is stripped from the grating. The difficulty of silvering these replicas satisfactorily has, however, prevented further progress, for the present at least.

In justice to Mr. Wallace I ought to say that, in a reply to a letter from me, he states he obtained his information from a patent I once took out in connection with the application of these grating replicas to colour photography; but the method there described is not the one I have adopted in making my replicas.

THOMAS THORP.

Whitefield, near Manchester, November 6.

THE article referred to by Mr. Thorp was, as mentioned in its first two lines, simply a *résumé* of Mr. Wallace's article in the *Astrophysical Journal*; and the statement corrected by Mr. Thorp was taken from that journal. It may be said, however, that the three gratings sent by Mr. Thorp have been compared, under similar conditions, and the results are in full accordance with the descriptions given above.

The second "Thorp" replica (15,120 lines) is a beautiful specimen in appearance, having none of the mottling which appears on the 14,438-line copy, but its first-order spectra are excelled in brightness by the first-order spectrum on one side of the latter, which is a similar replica to those that have produced such remarkably good results in eclipse and other observations when attached to just an ordinary hand-camera or a simple modification thereof.

THE WRITER OF THE NOTICE.

Aurora of November 15.

AN extraordinary aurora was seen here on November 15 at 6 p.m., in appearance something like a "stormy" sunset. The lower part of the aurora was illumined with a bluish-green light, and had an altitude at the centre of about 10°. Above this, extending for a further ten or fifteen degrees, the sky was brilliantly illuminated with streamers of a rosy red colour. I did not wait for its disappearance, but at 9.30 p.m. red streamers were visible in the N.N.W.

I looked for the Leonids this morning continuously from 1.20 to 2.35 from the vantage ground of the Dartmoor hills (1500 feet). I saw only one Leonid at 2.30, but the moon would prevent small ones being seen. The night was perfectly clear. ROWLAND A. EARP.

Buckfastleigh, S. Devon, November 16.

TRAVELLING this evening between Plymouth and Exeter, I pulled the screens over the light in my compartment to enjoy the moonlight, and was rewarded by seeing a fine display of aurora borealis, which was, I hope, witnessed by some other of your readers.

Between 9 p.m. and 9.30 p.m., when near Totnes, there was a bright flattened arch near the northern horizon, with white streamers rising from it at intervals, and very bright patches of rose-red, extending from north-east to north-west, and passing nearly overhead. At 9.15 one of these patches, on the right of the Great Bear, was a veritable "pillar of flame," and was more remarkable because of its contrast to the moonlight, which was very brilliant.

I think I am right in saying that a similar display has not been seen in the south of England for twenty-five or thirty years, and the last "rose-red" display that I can remember was in 1870. R. LANGTON COLE.

November 15.

A LUNAR THEORY FROM OBSERVATION.

ON June 3, visitation day at the Royal Observatory, Greenwich, the editor, who is a member of the board of visitors, asked me to write an account of my researches on the moon for NATURE. I delayed doing this for a few months in order to render my account more complete.

The moon's longitude contains about 150, and the latitude about 100, inequalities over $0''.1$. The arguments of these inequalities, and the mean longitude of the moon, require a knowledge of three angles connected with the moon, viz. the moon's mean longitude, the mean longitude of perigee, and the mean longitude of the node. The other angles involved in the arguments define the position of the sun, planets, the solar perigee, &c., and their values are to be determined from other observations than those of the moon.

The problem that I have had in view, therefore, is to determine the values of three angles as functions of the time, and to give a list of some 250 inequalities in all as accurately as possible.

Before the time of Newton, this was clearly the only way the problem of the moon's motion could be attacked, only the limit worked to was then more nearly $500''$ than $0''.1$. Since the time of Newton, the method has been almost entirely abandoned. Many mathematicians have attempted to calculate how the moon ought to move; the comparison between its observed and theoretical course has been rough in the extreme. No attempt has been made to verify from observation the coefficients of those inequalities for which a theoretical value had been calculated; observation has merely been required to furnish values for those constants which are theoretically arbitrary, and, as I shall show, the determination of these constants has often been rendered less accurate than was necessary by the tacit assumption that all theoretical terms had been accurately computed.

My point of view, as I have said, is that which was necessarily the only one before the time of Newton. Let us consider the application of this most ancient of all methods to the time when no observations were possible except a record of eclipses.

The two principal inequalities of the moon's longitude are

$$22640'' \sin g + 4586'' \sin (2D - g),$$

where g is the mean anomaly and D the mean elongation of the moon. Whenever the moon is either new or full, $2D = 0$; at such times, therefore, the two inequalities are indistinguishable from a single inequality

$$22640'' - 4586'' = 18054'' \sin g.$$

The "evection," as the smaller inequality is called, could evidently not have been discovered until the moon was observed near its quarters; moreover, a correct value of the eccentricity of the moon's orbit could never have then been obtained. On the other hand, so long as the sole object of astronomers was to obtain places of the new and full moons it did not matter whether the two inequalities were separated or not. Roughly speaking, material of a limited class is always good enough for generalisations confined to the same class; it is unsafe to extend the generalisation to a wider class, as in this instance it would be wrong to predict for the quarters of the moon from the formula $18054'' \sin g$.

When we have an extended series of observations and wish to determine whether a term $x \sin \alpha t$ runs through the errors, and, if so, to determine x, the theory of least squares directs us to multiply each error by $\sin \alpha t$ and add. But before equating

$$x\Sigma \sin^2 \alpha t = \Sigma \epsilon \sin \alpha t$$

we must pause and consider whether there may not be some other error $y \sin \beta t$ running through the observations such that

$$y\Sigma \sin \alpha t \sin \beta t \text{ is not zero.}$$

Now an interfering term of this sort may arise in two ways:—(1) β may differ so little from α that throughout the whole series of observations the difference between αt and βt does not take indiscriminately all values from $0°$ to $360°$; (2) the difference between αt and βt may be exactly equal to the mean elongation of the moon, in which case, since the observations are not uniformly distributed round the month, the two inequalities are liable to be confounded, just as the elliptic inequality and the evection were confounded in the early days of astronomy. Interference of the first kind can be eliminated by sufficiently extending the series of observations, but no amount of observations will obtain a correct result in the second case if the mathematical point is overlooked.

As a result of attending carefully to these considerations, I have succeeded in obtaining practically the same value of the eccentricity of the moon's orbit from two different series of observations compared with two different systems of tabular places. Hansen and Airy have given values of the same quantity differing by more than one second of arc. For the same reason, the value of the parallactic inequality of the moon obtained by me corresponds closely with the value of the solar parallax obtained in other ways. The consideration neglected by Airy in this case was the possibility of error in the tabular semi-diameter.

I have determined from the observations the coefficient of every term the coefficient of which was known to exceed $0''.1$. This constitutes, as I have said, the solution of the problem of the moon, as it presented itself before the time of Newton. It forms, too, the proper basis for comparing observation with theory. Previously the only thing known about the vast majority of terms was that whereas the apparent errors of Airy's tabular places frequently exceeded $20''$, those of Hansen's seldom differed from the mean of neighbouring observations by so much as $5''$, a quantity that might be attributed to errors of observation entirely. When, however, Newcomb in 1876 came to re-determine the value of the moon's eccentricity (in his immediate object he was not particularly successful owing to the neglect of the considerations I have just set down), he brought to light a term the coefficient of which is one second, and the argument of which was at the time unknown. The discovery of this term shows how unsafe it is to test the tables by the mere inspection of the series of errors of individual observations. However, in all my far more

exhaustive search I only brought to light one fresh inequality that runs through the errors, and that is to all appearance due to an error in the adopted parallax of the moon. My analysis, however, enables me to say that the solution of the problem of three bodies, as recently completed by E. W. Brown, is final. This might fairly be inferred from its agreement with Hansen and Delaunay, and from the numerous equations of verification employed throughout by Brown. But on my analysis a further remark may be based; not only are Brown's expressions a correct solution of his differential equations, but those differential equations do really represent, with all necessary accuracy, the problem of three bodies as presented by nature. The problem has been solved. If in the future a method as much superior to Hill's as Hill's is to Hansen's were to be invented, it would no doubt be worked out numerically, but no matter how ingenious it might be, the test of its accuracy would be—does it agree with Brown?

Another inference may be drawn from what I may call my empirical lunar theory. As the coefficients of solar terms are verified by Brown's calculations with a probable error of about 0″·04, that is presumably a measure of the accuracy of the constants. Moreover, on comparing the planetary and figure of earth terms with theory, larger discordances are found, especially in the figure of earth terms and in the Jupiter evection term. There is no special difficulty in obtaining these terms from observation; they are presumably determined as accurately as the others. Consequently, appreciable errors still exist in the theoretical values of the figure of earth terms and the Jupiter evection term.

Two suppositions of Hansen's on which he founded alterations of his tables have also been disproved, a mechanical ellipticity of the moon and an eccentricity in the face that it exhibits to the earth.

I come now to another class of investigations. The theory of the moon is deficient in that it does not explain the cause of a term of period of about 300 years and coefficient 15″ which observation shows to exist. This deficiency of theory is an inconvenience in many ways. It renders the determination of the secular acceleration of the moon, and the resulting measurement of tidal retardation, impossible from modern observations. It will be years, possibly two centuries, before from observation alone a really accurate estimate of the missing term can be given, unless, as is much to be hoped, theory accounts for it in the meanwhile. This unknown term renders difficult also the determination of the motion of the node and perigee. The position of the perigee is found by measuring an arc equal to the mean anomaly back from the mean position of the moon, and it is fairly clear that the unknown term is also an inequality of the anomaly. Hence the motion of the anomaly contains a periodic part that it is difficult to allow for accurately. I have determined the motion of the node and perigee over a period of 150 years, and I get small differences from the theoretical values recently published by Brown. Possibly the cause that produces the term of long period also produces a small motion of the node and perigee. Hansen assumed an empirical term of 240 years' period for this unknown term, but before Hansen's tables had been in the Nautical Almanac for twenty years, Newcomb found it necessary to change the period assumed to 273 years. Each assumption was associated with an argument in the hope that it would turn out to be the correct argument, but both in turn have been disproved. My own idea as to the term is that its period is more nearly 350 years, and I have no suggestions to make as to its argument. There are also smaller terms of 40 and 70 years' period approximately, or possibly the errors assume a more complicated form still. The periods are so long that the uncertainty is great.

The last section of my investigations deals with the ancient solar eclipses and the value of the secular accelerations. The three angles mentioned at the outset of this paper as requiring measurement contain terms proportional to the square of the time. It is evident that these terms become of considerable importance at remote epochs. Also on their accurate determination depend (1) the degree of assistance that astronomy can extend to chronologists; (2) a numerical estimate of the tidal retardation of the earth's diurnal rotation.

I have succeeded in showing that the alteration of two of the secular terms renders total, or at any rate central, five ancient eclipses which are partial according to the existing tables. This may, of course, be an extraordinary coincidence, but it seems more natural to suppose that records of the eclipses have come down to us because they really were striking phenomena worth recording—in one case the account says "fire in the midst of heaven," which seems to indicate the corona, and therefore totality. There is also the further fact in favour of these corrections that one of them is confirmed and the other supported by the ancient lunar eclipses. It may be of interest to mention that the most ancient eclipse of the five was communicated to me from the British Museum after I had deduced corrections from the other four, and that the corrections already found satisfied the condition of totality for the newly discovered eclipse. To such an extraordinary piece of luck the words of Virgil seem applicable:—

> "Turne, quod optanti divom promittere nemo
> Auderet, volvenda dies en attulit ultro."

It had occurred to me to wonder whether it was worth while to write to the British Museum, but the chance seemed so small that I was letting the days slip by without doing so.

Ancient eclipses, therefore, give an accurate measure of the relative distances of three points, the positions of the node, the sun, and the moon. The next question is, "Where is the equinox relatively to these three points?" My first interpretation of my results proceeded thus:—The position of the sun relatively to the equinox has never been called in question. We may be assumed to know it. Therefore my calculations determine the distance of the node from the equinox. This view of the matter, I now am glad to say, was found on examination to be untenable. In the words of Dante, what I spun in October did not last until the middle of November (the date of the first meeting of the Royal Astronomical Society):—

> "a mezzo novembre
> non giunge quel che tu d'ottobre fili."
> Purg., vi., 143.

The position of the node, in fact, may be inferred with certainty from the gravitational calculations of Prof. Brown. Hence my eclipse results determine the position of the sun as well as of the moon. The conclusion is that the sun's motion is being accelerated.

The most obvious hypothesis to account for this observed fact—it does not follow that it is the only hypothesis—is that the æther has a sensible retarding effect. It may seem curious that the resistance of the æther should accelerate the earth's orbital motion, but that undoubtedly would be the effect. The total energy must be diminished, and this implies that the planet falls in towards the sun and consequently revolves faster in its orbit. P. H. Cowell.

SCIENCE AND ART OF CRICKET.

THE golfing world already owes a debt of gratitude to Mr. Beldam for his "Great Golfers." This companion volume, setting forth on the same lines the styles of play of our greatest cricketers, cannot fail to appeal strongly to all lovers of the most English of our national games. The method adopted here is identical with that of the earlier book. Each of the many batsmen pictured has been photographed in one or more characteristic attitudes before, during, or after the striking of the ball, and after a careful study of every picture Mr. Fry has set down his own interpretation for the guidance of the reader. No better guide could have been got, for among the great cricketers of our day Mr. Fry stands conspicuous as one who has studied the art of cricket with phenomenal success.

The book is divided into two parts. In part i. (individualities) close on 300 photographs are given of eighteen of our best known batsmen, including Grace, Ranjitsinhji, Trumper, Fry, Hill, Jackson, Duff, MacLaren, and so on. In part ii. (strokes illustrated) the various kinds of recognised strokes are systematically discussed and illustrated by photographs of other great batsmen. There is, of course, a good deal of repetition of the same ideas in the letterpress of these two parts, but each has its own value. In the one case it is the individual batsman whose pose and actions are being studied; in the other it is the kind of stroke which is the object of discussion, and this is helped out by an appeal to the example of a number of different cricketers. The volume ends with a short but very practical and interesting chapter upon the art of timing with the camera. We learn that the operator sometimes used a finger release of the shutter and sometimes an electric. The latter method enabled Mr. Beldam to act, in same cases, both as bowler and photographer. The requisites for good work of this kind are complete knowledge of the mechanism and capabilities of the camera, thorough acquaintance with the game itself, and a delicacy of judgment which must be partly inborn and strongly developed by practice. We are not told what proportion of photographs taken were failures, but the beauty and clearness of the 600 here shown prove that Mr. Beldam is a master hand in the art of taking action-photographs.

Where almost every picture is admirable, and illustrates some essential part of a particular stroke, it is not possible to choose for reproduction any that might be regarded as representative. W. G. Grace, for example, is shown in twenty-six different attitudes, and all have some lesson to tell. In the photograph reproduced we have the finish of an on-drive, in which the turn of the body has aided powerfully in giving full effect to the stroke. The eyes are still looking at the spot where the ball was when it was struck. The whole series of photographs proves that all great batsmen follow the ball with their eye right up to the moment of striking. It is this which gives precision, just as in golf.

FIG. 1.—W. G. Grace—Finish of an On-drive.

Ranjitsinhji is figured in twenty photographs, and it is in the comparison of these with the attitudes of other cricketers that the limitations of the method of

[1] "Great Batsmen, their Methods at a Glance." By G. W. Beldam and C. B. Fry. Pp. xiv+716: illustrated by 600 Action-photographs. (London: Macmillan and Co., Ltd., 1905.) Price 21s. net.

instantaneous photography appear. Except in a few cases there is no appreciable difference between his attitudes and those of others; the characteristic style of Ranjitsinhji depends upon the rapidity of the successive movements which go to make the complete stroke, and this is necessarily lost in the momentary picture. One very characteristic poise of body is given in the eighteenth of the series of pictures of the Indian cricketer. Here we have the finish of the well known leg-glance. To quote from Mr. Fry's description:—"the unique part of the stroke is the foot work . . . the left foot is moved across right in front of the wicket, passing immediately across the right. The body from the hips upwards is twisted round towards the leg-side. The bat, at the instant it meets the ball, is perfectly upright just in front of the left knee. Playing this stroke in this way would be impossible for anyone less supple and less quick than Ranjitsinhji."

FIG. 2.—K. S Ranjitsinhji—Finish of the Leg-glance.

This is not the place for discussing in any detail the many different kinds of strokes recognised in cricket, though a good deal might be spoken regarding the dynamical principles underlying some of the methods indicated. For example, the lowering of the grip of the right hand in defensive strokes, as when the player plays back, is the obvious way of getting a more powerful couple to act on the bat and prevent it being rotated by the impulse of the ball. The player probably does not think of it in that way, but by experience he has found it to be the most effective method. The important distinction between wrist play and arm play is referred to again and again, and the value of wrist play insisted upon with great incisiveness. It seems to us, however, that Mr. Fry occasionally directs attention to evidence of powerful wrist play in certain attitudes where, strictly speaking, it does not to any marked degree exist. To bring out our meaning more precisely, let us suppose the batsman is taking his stand at the wicket. His first position with the bat resting in the block hole and his eyes looking towards the bowler gives him such a stance that when he rises upright with the bat drooping easily in front of him the face of the bat is directed straight towards the bowler. This is the zero position through which the bat will swing with its face always properly oriented. If he lifts both arms at the same rate by a rotation about a horizontal axis parallel to a line through the shoulders, the face of the bat will still look in the same direction; but if he moves the arms in any other way the conditions of the geometrical constraint imposed by the grip of the hands on the handle will necessitate a combined rotational and translational motion. Let anyone with bat in hand try to shape for a drive or a cut and endeavour at the same time to prevent the bat rotating round its own axis of figure, and he will find himself forced into the most awkward and constrained of attitudes. In the description of plate xxii., showing Grace preparing for the on-drive the finish of which we have reproduced, the last sentence reads thus: "If you study the turn of his bat you will see that in order to bring the face of the bat against the ball he must put in a pronounced turn of the wrist." The truth is that if the right elbow is kept down the bat must take the position shown, and the accompanying *turn* of the wrists is slight, involuntary, and *natural*, and mainly in the left wrist. In plate xxiii., reproduced above, the geometrical conditions of constraint compel a rotation of the bat round its axis in the opposite direction. Let anyone go through the motions slowly with the initial and final attitudes as shown in these two plates, and he will find the bat take the positions pictured passing through the zero position with face looking front, and through the whole motion he will not be *sensible* of any wrist action at all. The coordinated but geometrically

complex movements of arms and body give to the bat held by the two hands a complex screw motion which may approximately be described as a rotation about an oblique axis outside the bat altogether. Plate ii. of L. C. H. Palairet's series, showing his second position, is a perfect illustration of the remarks just made; with the attitude of body and arms as given it would be impossible for the bat to have any other position without an unnatural turn of the wrists.

The effect of the true wrist-action is well described in the later part of the book. It is as effective in cricket as in golf, bringing into play a rapid acceleration just at the instant of impact. It is at the foundation of all graceful batting. As Mr. Fry well remarks, "wrist-work is the chief secret of a versatile, neat and effective style."

The book is full of a great variety of most interesting and instructive points. Those among us whose cricket is a memory will almost wish they were twenty or thirty years younger if only for the chance of testing the soundness of the teaching of Messrs. Beldam and Fry's remarkable volume; while the youthful devotee eager to improve himself in the most attractive part of our national sport will get many valuable hints from a careful perusal of its pages and study of its pictures. C. G. K.

NOTES.

The council of the Royal Meteorological Society has awarded the Symons gold medal to Lieut.-General Sir Richard Strachey, G.C.S.I., F.R.S., in recognition of the valuable work which he has done in connection with meteorological science. The medal will be presented at the annual general meeting of the society on January 17, 1906.

The suggestion made by Prof. Milne in our correspondence columns this week, that an intercolonial meeting of the British Association should be held in London, is well worthy of consideration. Such a conference of representatives of science in British dominions beyond the seas and at home would strengthen the bond of union existing between them, and do something to coordinate the intellectual forces of our Empire. It is essential that men of science widely separated from one another should have opportunities of exchanging opinions upon investigations and results in which they are interested; and the advantages of such conventions are felt long after the meetings have ended. It is probable that Prof. Milne's proposal will meet with the approval of members of the association engaged in scientific work.

Members of the British Association who recently visited the Victoria Falls will be interested to learn that the small herd of hippopotami that frequents the islands above the Falls, and adds substantially to the attractions of the place, has again become troublesome. Apparently the animals have been irritated by the increasing traffic on the Zambesi; for a note in *South Africa* of November 18 states that several boats have been upset, causing one fatality and several narrow escapes. "Hippo, from any sentimental point of view," it is remarked, "are hardly the sort of things to be preserved as pets on a portion of the river where there is constant traffic, and it is to be hoped that every effort will be made to exterminate them before more serious accidents occur. . . . Those desirous of seeing the hippo in their natural haunts should find some more solitary spot where there is less danger to human life."

The *British Medical Journal* announces that the next meeting of the German Society of Experimental Psychology will be held at Würzburg on April 10–13, 1906. Reports will be presented on the following subjects:—(1) The relations between experimental phonetics and psychology (by E. Krueger); (2) experimental æsthetics (by O. Kuelpe); (3) the psychology of reading (by F. Schumann); and psychiatry and individual psychology (by R. Sommer).

The account of the surveying work connected with the construction of the Simplon Tunnel, in Nature of November 9 (p. 30), may be supplemented by the following final results, which have just been ascertained and are described in the *Times* of November 18 by Mr. Francis Fox. The actual measurements are as follows: The length of the tunnel, which is $12\frac{1}{2}$ miles, proves to be greater by 31 inches. The levels of the two galleries were within $3\frac{1}{2}$ inches of one another. As regards direction, the axis of the tunnel, driven from the north end, deviated 4 1-3 inches towards the west, whilst the line driven from the south end deviated 3 2-3 inches towards the east; consequently the greatest divergence from the true line was 4 1-3 inches, which is well within the calculated probable error.

A *Times* correspondent gives in the issue of November 20 a graphic description of the means taken to stamp out yellow fever in Panama. The first cases of the disease were concealed, and it was not until a serious epidemic was in progress that President Roosevelt, on his own initiative, Congress having refused to aid him, appointed Judge Magoon to Panama as Resident Governor of the canal zone with autocratic power. The prevalence of fever was bad enough, but the demoralisation of public spirit in the American colony was worse. Governor Magoon found that, while some in utter panic were fleeing from the isthmus as a plague-spot, others had fallen into a state of cynical bravado. They professed contempt for the mosquito theory of disease dissemination, and refused to obey the preventive rules which had been formulated. They took a boastful delight in exposing themselves to mosquito bites, and tore holes in the netting which had been placed over the windows of the office buildings and hotels. The Governor soon changed all this, expressed his own fear of the disease, insisted that the evidence of the transference of the disease by mosquitoes was overwhelming, and arranged for the fumigation of every building in the city. Medical inspectors were also appointed who daily examined every inhabitant. The effect of these measures is shown by the figures of the incidence of the disease:—in May there were 38 cases; in June 62 cases; in July, after the institution of these measures, 42 cases; in August 27 cases; in September 6 cases; and since then not a single case, although a reward of 50 dollars, gold, has been offered for a notification.

Mr. C. O. Stevens, writing from Bradfield, Reading, states that on Friday last, November 17, widespread attention was attracted and curiosity aroused by sounds as of heavy-gun practice and rifle firing that made themselves felt, as well as heard, in the neighbourhood for miles around. They occurred, on and off, from about 11.30 a.m. until 4 p.m.

To the Irish Fisheries Board we are indebted for a copy of the first instalment of a list of the marine copepod crustaceans of Ireland, by Mr. J. Pearson, published as No. 3 of "Scientific Investigations" for 1904. The author states that previous students have mainly confined their investigations to the pelagic types, and that consequently

much remains to be ascertained concerning the parasitic and bottom-dwelling forms. The present section deals with littoral types and those infesting fish.

IN the report of the council of the Natural History Society of Northumberland, Durham, and Newcastle-upon-Tyne, attention is directed to the important work which has been recently accomplished in the matter of scientific publications. Unfortunately, this has somewhat crippled the society's resources, and unless additional support be accorded a pause must be made in the good work. It is estimated that the total number of visitors to the society's museum during the year will be about 17,000.

THE October issue of the *Emu* contains some beautiful photographic illustrations of the haunts and nests of the Australian lyre-bird, as well as of the bird itself. It is, however, sad to learn that, in the opinion of Mr. Kitson, the author of the accompanying notes, the lyre-bird is destined to disappear ere long from the Victorian bush unless it develops the habit of nesting in trees, as is occasionally its practice at the present time. The main persecutor is the European fox, which has been introduced with only too much success into its haunts. In South Gippsland, on the other hand, man is the criminal, and breech-loaders, forest spoliation, and bush-fires will, it is thought, before long complete their fell work, and render the lyre-bird unknown in a district where it formerly occurred in thousands. A supplement to this issue contains a useful "key" to the birds of Australia drawn up by Mr. A. C. Campbell on the "dichotomous" plan, that is to say, by according two contrasting diagnostic characters to each species.

WE regret to have to record the death of that eminent French naturalist Jean Frédéric Émile Oustalet, of whom a brief obituary notice is published in a recent issue of *La Nature*, to which journal the departed zoologist was a constant contributor. Born at Montbéliard on August 24, 1844, Oustalet passed the whole of his scientific career in the service of the Paris Museum, which he entered as an assistant in 1875. In August, 1900, he became professor of "mammalogy," with special charge of the menagerie, and co-director of the École des Hautes Études. He died "in harness" at St. Cast (Côtes du Nord) on October 26. The laureate of the Institute of France in 1877, Mr. Oustalet was secretary to the committee for ornithological investigations, and president of the Ornithological Congress in 1900. He was a Chevalier of the Legion of Honour, and had likewise received decorations from other countries. Among his more important works may be cited "Recherches sur les Insectes fossiles," "Monographies des Mégapodes," and "Les Oiseaux de la Chine."

THE *Journal of the Royal Sanitary Institute* for November (xxvi., No. 10) contains an address by the Duke of Northumberland on the occasion of the opening of the new hospital for infectious diseases at Newburn; Prof. Kenwood's address on the public health delivered at the opening of the medical session at University College; particulars of model cottages at Earswich, York, by Mr. Appleton; and a discussion on aspects of the pure milk question, together with notes, reviews, &c.

THE Michigan State Agricultural College Experiment Station has issued two useful Bulletins (June). No. 229 details interesting observations by Mr. Marshall on the associative action of bacteria in the souring of milk. Experiments prove that the activity of lactic acid-forming bacteria may be much increased by admixture with another bacterium which itself does not produce lactic acid. In No. 230 Mr. Sackett describes several bacterial diseases of plants prevalent in Michigan, viz. pear blight, bacteriosis of beans, black rot of cabbage, wilt of cucumber, soft rot of sugar beet, and blight of Irish potato, tomato, and egg-plant.

IN the *Arkiv for Botanik* (vol. v., No. 3) Dr. J. Eriksson takes up the subject of the origin and spread of rust diseases in plants to combat the views of Klebahn, Marshall Ward, and others. Criticising the argument that the *uredo*-stage can carry infection through a severe winter, he lays stress on the want of proportion between the development in autumn and the intensity of the disease in the following summer.

As the first of a series of articles to appear in the *Indian Forester* on Indian forest fungi, Mr. E. J. Butler describes a trichosporium disease observed in Casuarina plantations; the fungus spreads through the cambium and ruptures the bark. Considerable interest attaches to the notes by Mr. F. B. Manson on the preparation and sale of rubber grown on the rubber plantation at Mergui, from which it is evident that good Para can be produced in Lower Burma.

IN a small brochure ("Die Lichtentwickelung in den Pflanzen") Prof. H. Molisch deals with the subject of light emission by plants. The production of light is confined to fungi, bacteria, and Peridineæ in the plant world. Prof. Molisch determined that the luminosity of meat is caused by a bacterium, and showed that the bacterium can generally be produced in a few days by partially immersing a piece of meat in brine. The emission of light from wood has been traced to the same source, and similarly decaying leaves of oak and beech may become luminous. The connection between nutrition, growth, and luminosity has been studied by Beijerinck. As to the teleological factor in the production of light, little is known except that it is an oxidation process; Prof. Molisch postulates a substance, photogen, that produces light waves in the presence of oxygen.

A SCHEME of no little interest, and worthy of generous support, has been initiated by the Midland Reafforesting Association for planting trees on the spoil banks in the black country. Anyone who has traversed the road from Wolverhampton to Dudley by way of Gornal will have realised something of the former beauty of this district. The object of the association is to prove that plantations are still feasible on the unsightly pit-mounds that cover the land. Last autumn a six-acre plot was planted at Wednesbury and a small model plantation was formed at Old Hill. The extension of the work that is now in progress makes it necessary to employ a paid organising secretary. To provide funds for this purpose, and to obtain a larger balance than is at present available as working capital, Sir Oliver Lodge, the president of the association, is appealing for contributions. The honorary secretary is Mr. P. E. Martineau, Bentley Heath, Knowle, Warwickshire.

SEVERAL interesting memoirs have been issued by the Geological Survey of Queensland. One of the most valuable of these is a general index (Publication No. 197) to the various reports issued by the survey (Nos. 177 to 196), compiled by Mr. Russell Dixon. In Publication No. 196 Mr. B. Dunstan gives notes on the gold deposits near Mount Ubi, on the iron ore of Mount Lucy, on testing samples for prospectors, on monazite in Queensland, on a soil survey for Queensland, on boring for coal near Townsville, and on the testing of Queensland coals. He

also gives some mineralogical notes on agate pebbles occurring in abundance on the surface of decomposed basalt at Little River, on penetration-twin crystals of gypsum from Eukalunda, on tellurides of gold, silver, and lead (hessite and altaite) from Gympie, and on calcite crystals with pyrites inclusions from Golden Gate, Croydon. In Publication No. 198 Mr. Lionel C. Ball describes the occurrence of gold, platinum, tinstone, and monazite in the beach sands on the south coast of Queensland. The results obtained indicate that this is a favourable field for the use of a dredger. In Publication No. 199 Mr. Lionel C. Ball gives a preliminary report on the recent discovery of gold at Oaks View, near Rockhampton. The ore is a soft ferruginous material resulting from the alteration of an original serpentine. In Publication No. 200 Mr. Walter E. Cameron describes the central Queensland (Dawson-Mackenzie) Coal-measures. The coal is of permo-Carboniferous age, and a promising forecast is given of the great resources of this portion of Queensland in high-class steam-coal.

THE pretty and well known lecture experiment showing the alternations between longitudinal and torsional oscillations in a suspended spiral spring carrying a weight was described by Wilberforce in 1894. In the *Festschrift* commemorative of the seventieth birthday of Adolf Wüllner (Leipzig: B. G. Teubner, 1905) Prof. A. Sommerfeld describes some further experiments with spiral springs and discusses their use in the determination of Poisson's ratio. The following methods are distinguished:—statical observations, observations of the separate oscillation periods, construction and measurement of the Lissajou curves, determination of the conditions of resonance.

IN the *Arkiv* for mathematics, astronomy, and physics of the Swedish Academy, Mr. W. Walfrid Ekman gives an investigation (in English) on the influence of the earth's rotation on ocean currents. It had been observed by Dr. Nansen on the *Fram* that the drift produced by a given wind did not follow the wind's direction, but deviated some 20°–40° to the right, and a mathematical investigation by the writer of the present paper showed how this deviation could be accounted for by the earth's rotation. In the present communication account is taken of the influence of continents and of neighbouring currents. The calculations show the existence of a surface current tending somewhat to follow the shore lines, but deviating 45° from the direction of the wind in the absence of boundaries, a midwater current with a velocity almost uniform and parallel to the coast, lastly a bottom current compensating for the flow of water towards or from the land in the surface current.

THE *Popular Science Monthly* for November contains a note by Prof. Mansfield Merriman on the "cattle problem" of Archimedes. This problem occurs in the form of a poem of forty-four lines in a manuscript in the library of Wolfenbüttel, and it was brought into notice by Lessing shortly after his appointment as librarian there in 1769. The problem consists, in the first place, in determining the total number of cattle grazing on the plain of Sicily, divided into white, black, dappled, and yellow bulls and cows, from seven equations of condition connecting the numbers in the eight various categories. The problem in this form is easy, but a further rider imposes the additional conditions that the number of white and black bulls shall be a square number, and the number of dappled and yellow bulls a triangular number. Amthor showed in 1880 that numbers satisfying these conditions could be found, but instead of the total number representing a possible herd of cattle, it would consist of no less than 206,545 digits. Finally, in 1889 Mr. A. H. Bell, in conjunction with two other mathematicians, began the work of solution, and in the course of four years determined the first thirty or thirty-one and the last twelve digits of the actual numbers. It is, however, pointed out that to determine all the 206,545 digits would occupy a thousand men for a thousand years.

IN No. 2, vol. xxii., of the *Astrophysical Journal* Mr. W. W. Strong, of the Dickinson College, Carlisle (Pa.), describes the results obtained from a series of experiments on the spectrum of the magnesium spark under various conditions. The spectra were photographed with a 4-inch Rowland grating having 14,400 lines to the inch. Using magnesium poles, he found that the "principal series" lines (λλ 2802 and 2795) and the line at λ 2852 were reversed in the end-on positions, but if a copper or iron pole were substituted for one of the magnesium poles, and the remaining magnesium pole was placed *away* from the slit, the reversals did not occur. This seems to indicate that the reversals are caused by the surrounding vapour of magnesium, and, to prove this, the spark was made to pass between an iron and a magnesium pole through a fine hole. For holes of less than 0·5 mm. in diameter this "reversing layer" was entirely cut off, and the spectrum of the spark between the hole and the *iron* pole *never* showed any reversal. Other results, in connection with other lines, were also obtained, but an attempt to get a measurable "Doppler" effect was defeated by the diffuse nature of the lines.

THE Journal of the Meteorological Society of Japan for June last contains several useful articles, including one (in Japanese) by I. Hattori on oyster development and meteorological conditions, and notes on the climate of the Bonin Islands (in English) by T. Okada. In the summer of 1901 a station was established by the Tokio Meteorological Office at Peel Island, one of the largest of the group; the station is situated in lat. 27° 5′ N. and long. 142° 11′ E. In addition to the automatic records, observations have been regularly made at 10h. a.m. and 2h. p.m., and the results are published for the years 1902–4. The principal facts relating to this isolated Pacific station may be interesting to some of our readers. The mean annual temperature is 71°·8, the mean monthly maximum being 79°·5, in August, and the minimum 61°·5, in January; the highest temperature recorded was 91°·4, in September, and the lowest 45°·5, in February; no frost or snowfall has been recorded, and vegetation is astonishingly luxuriant. North-westerly winds blow almost constantly from December to February, inclusive; the easterly monsoon prevails from July to October, inclusive. The rainy seasons are June and September, and the driest months are April and January; the total annual rainfall is about 54 inches, and, on an average, there are 147 rainy days in a year. The mean annual relative humidity is 75 per cent.

IN the October number of the *Journal de Physique* M. H. Buisson gives particulars of a new determination of the mass of a cubic decimetre of pure water. The author criticises the usual method of determining the volume of a solid by measurement of the linear dimensions; in his experiments two parallelepipeds of quartz, almost cubes, of four and five centimetres edge were used, their densities, and hence their volumes, being determined by the hydrostatic method, after correcting all the data to 0° C. The geometrical dimensions of the cubes were then ascertained by two distinct optical methods based on the

principle of interference. By a comparison of the two sets of values, the ratio of the litre to the cubic decimetre was found in two determinations to be 1·000026 and 1·000029 respectively. The error on the kilogram is thus +26 to +29 milligrams.

MESSRS. SWAN SONNENSCHEIN AND CO., LTD., have published a third edition of "Sanatoria for Consumptives," by Dr. F. Rufenacht Walters. The book, the first edition of which was reviewed in NATURE for July 6, 1899 (vol. lx. p. 221), gives a critical and detailed description, together with an exposition, of the open-air or hygienic treatment of phthisis.

DR. H. C. VOGEL, director of the Astrophysical Observatory at Potsdam, has edited the third edition of Newcomb-Engelmann's "Populäre Astronomie," published by Mr. W. Engelmann, Leipzig. Many additions have been made, both to the text and illustrations, particularly in the sections devoted to spectrum analysis, photometry, photography, and other branches of astrophysics; and the whole work has been satisfactorily revised. Short biographies of deceased astronomers from Thales to Keeler, arranged according to their years of birth, are given near the end of the volume.

WE have received from Mr. H. K. Lewis, 136 Gower Street, W.C., a copy of No. 23 of his *Quarterly List* of additions to the circulating library. The list contains more than 100 titles, and includes several important new books and new editions on the various subjects covered by the library. There are brief notes to most of the books which, while not pretending to give the subscriber an exact idea of the book, enable an opinion to be formed on its general scope. On looking through the books included we notice that, since the first number appeared, considerable extension in the scope of the library has taken place. The library has been long known as a useful medium for the supply of medical literature, and the inclusion of all branches of technological and general scientific books, commenced some two or three years ago, should add to its value.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A COMET, 1905*b*.—A telegram from the Kiel Centralstelle announces the discovery of a comet by M. Schaer at Geneva on November 17. At 8h. 7·8m. (M.T. Geneva) the position of the comet was

$$\text{R.A.} = 4\text{h. } 22\text{m. } 32\text{s., dec.} = +86°.$$

The apparent daily movement of this object is given as $-54°$ in R.A. (*i.e.* 3h. 36m.) and $-1°$ in declination.

A second telegram from the same source announces that the comet was observed at Bamberg on November 18·075. The position, at 6h. 50·6m. (Bamberg M.T.), was

$$\text{R.A.} = 0\text{h. } 58\text{m. } 19·5\text{s., dec.} = +80° \ 40' \ 5''.$$

It thus appears that this object was first seen near to Polaris, and is now travelling quickly down through Cepheus towards Cassiopeia.

NOVA AQUILÆ NO. 2.—The results of a number of observations of Nova Aquilæ are recorded in No. 4052 of the *Astronomische Nachrichten*.

On September 29 Prof. Wolf recorded the magnitude of the Nova as 9·6–9·7, which indicated scarcely any decrease in the brightness since September 17.

A photograph, taken on October 16 with fifty-six minutes' exposure, showed, however, that the Nova's magnitude had decreased to 10·8, that is to say, it had fallen about 1·2 magnitudes in seventeen days. On this photograph the image of the Nova is surrounded by a faint uneven halo 1′ or 2′ in diameter.

THE TENTH SATELLITE OF SATURN.—No. 9, vol. liii., of the Harvard College Observatory Annals contains an account, by Prof. W. H. Pickering, of the discovery of Saturn's tenth satellite, to which the name Themis has been allotted.

So far no variation of the satellite's brightness has been detected, its magnitude remaining constant at about 17·5. As this magnitude is beyond the power of existing telescopes, the satellite can never be observed *visually* until more powerful instruments are available. The probable diameter of Themis is about 38 miles; the orbit of the satellite is inclined about 39°·1 to the ecliptic, and its eccentricity and semi-major axis are about 0·23 and 906,000 miles respectively. The period of revolution is 20·85 days. As the observational data are, as yet, so few, all the above values are to be considered as only approximate. A drawing accompanying the description represents the orbit diagrammatically.

Owing to its great eccentricity, the orbit of Themis crosses the orbits of both Hyperion and Titan, and, when near to these bodies, the newly discovered satellite must suffer enormous perturbations, the results of which are discussed in Prof. Pickering's paper.

THE EVOLUTION OF THE SOLAR SYSTEM.—Another alternative to Laplace's theory of the formation of planetary systems is suggested in an article by Mr. F. R. Moulton, of Chicago University, in the *Astrophysical Journal* for October. In 1900 this writer and Prof. T. C. Chamberlin examined the older hypothesis from the dynamical standpoint, and found so many conclusive contradictions as to lead them to abandon it.

The theory now suggested supposes that the planets and their satellites have been formed around primitive nuclei of considerable dimensions existing in a spiral nebula probably similar to those which Prof. Keeler showed to be many times more numerous than all the nebulæ of other types.

The growth of each nucleus was caused by the gradual accretion of smaller masses, and the method of this growth which is suggested accounts for all the different types of bodies now found in the solar system, and for their present motions and velocities, on dynamical principles.

The original spiral nebula is supposed to have been formed by the near approach of another star to the body which is now our sun. This exterior attraction set up tides in the solar matter, and, being continued, actually caused immense masses to be ejected and drawn out into the spiral form. On this assumption the spiral would emerge from the central nucleus in two directions, on opposite sides, and this is the form generally shown on photographs of such nebulæ.

Mr. Moulton's paper considers at length the explanation, on this hypothesis, of the existing conditions, and a fuller exposition of the theory is promised in a new work which is to be published shortly.

CATALOGUE OF VARIABLE STARS.—No. 7, vol. liii., of the Harvard College Observatory Annals contains a second supplement to the provisional catalogue of variable stars which was issued in a previous volume of the Annals. The original intention of the Harvard authorities was to publish a supplement, similar to the one issued in 1903, every five years, but the large number of variables recently discovered renders a change of plan necessary. More than 400 variables are included in the present supplement, many of them belonging to the nebulous regions investigated by Miss Leavitt.

During 1904 the number of variable stars was increased by 503, of which 431 were discovered photographically at Harvard. The card-catalogue of variables which is being compiled at Harvard now comprises about thirty-five thousand cards.

STAR CALENDAR FOR 1906.—We have received a copy of a very useful star calendar compiled by [H.P.H.], and published by Messrs. Hirschfeld Bros. The calendar consists of four cards designed to hang on the wall for ready reference. Each card contains the ordinary date-calendar for the quarter, a table showing the positions of the planets in regard to the constellations, and a star map so marked that the constellations and stars which may be observed on any evening during the quarter, may be instantly recognised by their relative positions in regard to the cardinal points and to the zenith. The price of the calendar is 1*s*. net.

NEW MUSEUM AND LABORATORIES OF ZOOLOGY AT LIVERPOOL.

THE new museum and laboratories of zoology of the University of Liverpool were opened on Saturday last, November 18, by the Earl of Onslow, formerly President of the Board of Agriculture and Fisheries, and now chairman of committees of the House of Lords.

The history of the department of zoology at Liverpool and the character of the new buildings are described in a pamphlet issued by the university, and abridged at the end of this record of the opening ceremony.

Preparatory to the actual ceremony of inauguration at the new building, there was a large gathering in the arts theatre of the university of guests of the council and senate of the university. Apologies and letters of regret for unavoidable absence were received from the president of the Royal Society, Sir Archibald Geikie, Prof. Ray Lankester, Sir Henry Roscoe, and many other men of science. A resolution passed at the meeting of the Linnean Society of London on November 16, signed by the officers, and congratulating the University of Liverpool and their president (Prof. Herdman) on the new laboratories, was received.

Dr. Nansen had accepted the invitation and hoped to be present, but at the last sent his regrets and a telegram saying:—"Hearty congratulations to the Zoological Department of the University of Liverpool.—NANSEN."

Lord Onslow was introduced to the assembly by the Chancellor, the Earl of Derby; and in the course of his remarks he is reported by the *Liverpool Daily Post and Mercury* to have spoken as follows:—

LORD ONSLOW ON SCIENCE AND THE STATE.

In the first place he wished to congratulate the University of Liverpool on their decision to set apart a sum sufficient properly to equip the museum and laboratories of the natural history and zoological department of the university. He thought that was a wise step, but it was a step which could only have been accomplished, in common with all the rest of the work of the university, by the great liberality of the captains of industry in Liverpool, who had realised that the application of science to commerce was one of the most important things for commerce itself. When he looked back on the list of benefactors to the Liverpool University, he found the names of Brunner, Holt, Tate, Johnston, Rathbone, and others, and he was struck by the fact that in Liverpool at any rate the application of science to commerce was thoroughly appreciated. Although there was in this country a great amount of private wealth and of private benefaction, he was afraid it must be confessed that the amount which had been devoted to the promotion of university education "pales its ineffectual fires" before what had been done in America. In the United States of America as much as 7,000,000*l.* had been bequeathed or given in two years to the purposes of university education. What was the reason for that? He thought that in a large measure it was due to the great difference between the United States of America and this country. The difference was that in the United States there were no hereditary honours or titles, and if a man wanted the future generation to have a record of his existence it could only be done by associating his name either with a university or with a chair in that university, or by some other great benefaction. The result was that the United States had rich universities, such as that of Cornell, founded by individuals, and he confessed that if he were a man of great wealth he would much rather posterity would remember him as having founded a university or a chair of a university than as having been a liberal subscriber to the funds of his party. Though a good understanding existed between this country and other Great Powers, provision should be made for the war in commercial supremacy. What were the armaments with which we were to provide ourselves for the purposes of defence in the war of commercial supremacy? They were those provided by science and by scientific research. Fortunately for us, the inventions of science could not be patented in the interests of any one particular country, but the slightest improvement upon them could, and it was those improvements, arrived at by scientific research, which would make or mar the supremacy of any country in commerce. The power of adding to a train-load that could be carried by a locomotive in the other hemisphere might make a difference of two shillings in the price of corn, which was the shuttlecock between the political parties at the present time. It was the same with all our manufactures. The greatness of England in the past century had been due to men of science like Faraday, Watt, Stephenson, and Kelvin. Were we doing all that we ought to see that any latent genius in the whole of the British nation got the opportunity to come out, and to give to the world those great triumphs of scientific research from which this country had so enormously benefited? He thought it must be confessed that until quite recently education in this country was in a chaotic state. Even now it was only in favoured cities and places that there was anything like an educational ladder by which an intelligent boy at the national school could, without cost to his parent, work his way up until he took a university degree, and could devote himself to scientific research for the benefit of his fellow-countrymen. He had great hopes that a spirit was arising in the nation now which saw the necessity of those educational facilities, and that by the assistance and liberality of our citizens they would build up from the lowest to the highest facilities that every citizen could avail himself of. There were two great public questions before the people

FIG. 1.—New Buildings of the Department of Zoology, University of Liverpool.

of this country upon which the prosperity of the future of the country depended. One of them was the re-organisation of the Army, and the other was the organisation of the education of the country. Both those questions required the expenditure of large sums of money, and he did not believe that under the present system it would be possible to obtain those large sums unless in some manner or another they could see their way to broaden the basis of taxation. When the business of the fisheries of the country was handed over to his (Lord Onslow's) department he naturally expected, as an ignorant Minister did, that he would find the broad lines upon which it was expected that he should shape his policy already laid down by experts and men of science. But instead of that he found a wall of ignorance as regarded everything that affected the biological and physical condition of our territorial waters. What they wanted to know was by scientific research whether anything could be done to stem the depopulation of the ocean if that depopulation was actually know how to protect human beings from the danger of eating contaminated shell-fish. They had done much in the Liverpool University for the study of tropical diseases; they had ascertained much to protect the lives of their fellow-subjects who went out to the malarial coasts of West Africa; he sincerely hoped that they would be able also to show them how they could avoid pollution from the contamination of shell-fish. He hoped that all who had worked in the laboratories of the university would be stimulated to greater efforts by the better buildings in which they would be housed.

The Chancellor read a communication received from Sir Thomas Elliott, Permanent Secretary of the Board of Agriculture and Fisheries, intimating that the Board were pleased to award the university a grant of 200*l.* for the financial year ending March, 1906, in respect of the zoological work carried on in connection with the fishing industry, and conveying the congratulations of the Board on the completion of the zoological museum and labor-

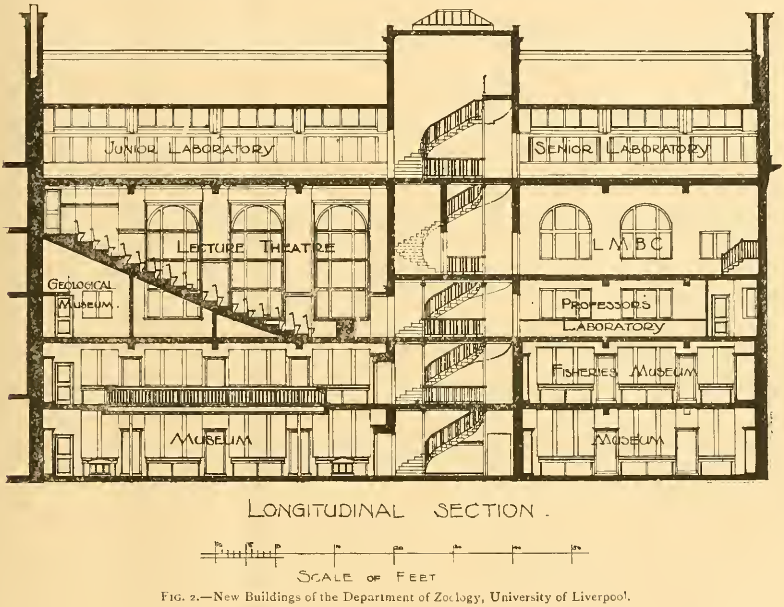

FIG. 2.—New Buildings of the Department of Zoology, University of Liverpool.

going on. That work must be divided under two heads—statistical and biological. The statistical work could not, of course, be properly performed by a university such as that. That was a matter which must be taken in hand by the central authority. He looked very largely to the Lancashire Sea Fisheries Committee, acting in conjunction with the University of Liverpool, to pursue the biological part of those inquiries. He was in hopes that when the expenditure of this country upon the international investigation of the North Sea came to a close there might be national funds available for assisting them in the research which they had undertaken for some time past, and which he could not doubt but with the opening of those new buildings would be largely stimulated and increased, and that thereby they might be assisted by them to solve problems which were great and national. There was also the great and important question of the connection of human disease with shell-fish. They wanted to find out to what extent there was contamination in shell-fish, and also what was not dangerous to the human frame. It was really of the very greatest possible importance that they should

atories, which they hoped would be of service "both in the advancement of scientific knowledge and in the solution of many problems of importance to the fishing industry." Sir Thomas Elliott afterwards spoke.

Replying to a vote of thanks moved by Mr. E. K. Muspratt and seconded by Sir John Brunner, M.P., Lord Onslow said he was not by any means alone in his appreciation of not only the benefit, but the absolute necessity of all Government departments in their respective spheres availing themselves of the advantages of scientific research. It applied not only to Government departments, but equally to all the great industries, to the Navy and the Army, and to every branch of national enterprise. In regretting that the 200*l.* contribution to which Sir Thomas Elliott had referred was regarded as small, Lord Onslow said it was not the Board of Agriculture who was rich, it was the Chancellor of the Exchequer, and when they got a few thousands out of the Chancellor of the Exchequer for all the purposes of agriculture and fisheries, they thought they had done very well when they were able to contribute 200*l.* to one place.

The proceedings in the arts theatre then ended, and Lord Onslow and the council and senate and guests walked through the university grounds to the new zoology buildings, where, after a short speech by Prof. Herdman, Sir John Murray addressed the assembly upon oceanography. Mr. R. B. Haldane also delivered a brief speech, in the course of which he remarked that by obtaining the grant of 200*l*. from the Chancellor of the Exchequer Sir Thomas Elliott had established a principle and connected the University of Liverpool with His Majesty's Government.

THE DEPARTMENT OF ZOOLOGY.

The Derby chair of natural history was established by the fifteenth Earl of Derby in 1881—an appropriate gift from a descendant of the scientific founder[1] of the celebrated zoological collections once alive at Knowsley and now secured to Liverpool in the Derby Museum of the Public Galleries. The first Derby professor was appointed at the end of 1881, and thus natural history was one of the three or four scientific departments with which University College opened in January, 1882. The work of the Liverpool Marine Biology Committee has been so intimately bound up with the Natural History Department during the last twenty years that, although not, strictly speaking, a part of the university organisation, it is impossible to omit a brief record of its history. Established for the purpose of exploring the fauna and flora of Liverpool Bay and the neighbouring parts of the Irish Sea, it brought a number of the local field-naturalists into close relation with the university department and laboratory methods, it gave rise to dredging expeditions and observations and experiments at sea, which led on in later years to sea-fisheries investigations, and it resulted in the accumulation of collections which have proved of considerable interest and scientific value. The "local" collection in the museum of the new buildings has been almost wholly obtained through the work of the L.M.B.C.

Probably the most important outcome of this exploring work has been the establishment of a marine biological station on the west coast of England. After five years' use of an old Dock Board observatory on Puffin Island, off Anglesey, the committee moved their marine station to Port Erin, at the south end of the Isle of Man, where they have now a substantial, new, two-storeyed building, measuring 95 feet by 45 feet, containing laboratories, an aquarium, and a fish-hatchery, and provided with a large, open-air, sea-water pond for the spawning and rearing of fish. As to the results obtained from this institution (which is under the direction of the Derby professor, and is worked in connection with the university department), it will suffice to state that during the last year thirty-six investigators worked in the laboratory, about five millions of young plaice were sent out to sea from the fish-hatchery, and more than thirteen thousand visitors paid for admission to the aquarium.

It was certainly to this marine biological work in the past that the natural history department owed in the first instance that connection with the local sea-fisheries authorities which has recently developed into a formal agreement between the university and the Lancashire and Western Sea Fisheries Committee. The scientific work of the local fisheries district is carried on in the laboratories by assistants paid by the Fisheries Committee, and the professor has been appointed honorary director of the scientific work, and furnishes an annual report on the work of the fisheries laboratory. A share of the laboratory accommodation in the new buildings will be devoted to the furtherance of the work of the Liverpool Marine Biology Committee, of the Lancashire and Western Sea Fisheries Committee, of economic entomology, and of other useful applications of zoology.

It has been recognised for some years that the accommodation in the old college buildings was quite inadequate to meet the wants of this department, and although some extensions had been made, such as a wooden fisheries laboratory on the roof and a convenient little museum (given about ten years ago by the late Mr. George Holt), these were temporary expedients which in some ways only emphasised the pressing need for new and much larger buildings. Research work offered to the department was hampered, and in some cases had to be declined for want of room. These facts were given expression to in the statements of needs drawn up in connection with the university movement of 1901–2, and after the establishment of the university a sum of 18,000*l*. was voted to the council by the university committee in October, 1902, for the purpose of erecting and equipping a new department of zoology, to contain a museum and a lecture theatre, the necessary students' laboratories, and also accommodation for sea fisheries investigations and other lines of marine biological research.

[1] The thirteenth Earl of Derby, President of the Linnean Society, 1828–1833, and subsequently President of the Zoological Society.

THE NEW BUILDINGS.

This zoological institute has a frontage of 123 feet on the western side of Brownlow Street, is 41 feet from front to back, and 84 feet in height from the street level. It is built of red pressed brick relieved with white sandstone from the Storeton quarries in Cheshire. The building consists of a central tower containing the entrance hall and staircase and some of the smaller rooms on each floor, and of two blocks, the north and the south, which have been treated rather differently as regards internal structure. The south block has only three main floors, while the north has five in the same height. The central tower extends a storey higher. In the south block the three floors accommodate (1) the museum with its large gallery; (2) the lecture theatre; and (3) the large junior laboratory at the top of the building. In the north block, on the two lower floors there are extensions of the museum to receive special collections, and the rest of the space is devoted to the senior class-room, senior and honours students' laboratories, the departmental library, and rather large laboratory and store-room accommodation for the sea fisheries department, the work of the economic entomologist, of the marine biological committee, and other practical applications of zoology. In the central tower, along with the staircase, there are small rooms for the professor and two demonstrators, the laboratory assistant, with diagram, chemical, aquarium, photographic, macerating rooms and students' lavatories.

GEOLOGY AT THE BRITISH ASSOCIATION.

IN Section C the papers read were largely on subjects of local interest, and in many cases by South African geologists. The delivery of the presidential address in this section having been fixed for the meeting at Johannesburg, the proceedings at Cape Town were opened with a short address of introduction by the president, followed by a lecture by Mr. A. W. Rogers, the director of the Colonial Geological Survey, on the outlines of the geology of the Cape Colony.

Among the subjects discussed, the Karroo claimed a considerable share of attention. Prof. R. Broom, in a paper on the classification of the Karroo beds, retained the division into Dwyka, Ecca, Beaufort, and Stormberg series. He subdivides the Beaufort series into three, and the Stormberg into two parts on reptile evidence, and correlates the various divisions with European strata thus:—Dwyka and Ecca series with Lower and Middle Permian, Lower Beaufort beds with Upper Permian, Middle and Upper Beaufort beds with Lower and Upper Trias, Lower Stormberg beds with Rhætic, and Upper Stormberg beds with Lower Jurassic.

Mr. A. L. du Toit gave an account of the Stormberg formation in Cape Colony. This uppermost division of the Karroo beds consists of a considerable thickness of nearly horizontal sandstones, shales, and volcanic rocks, and includes (in descending order):—(4) Volcanic Beds; (3) Cave Sandstone; (2) Red Beds; (1) Molteno Beds. The formation covers a considerable area in the east of the colony, in the Stormberg and Drakensberg districts, the summits of the mountains being commonly formed of the lava flows of (4). The sediments were deposited in an inland sea, the "Karroo Lake," the southern shore-line of which ran along the present coast-ranges of the colony, and thence north-eastward, outside and parallel with the coast-line of Natal. The author suggests the correlation of the Volcanic Beds and Cave Sandstone with the Rájmahál series of India (Middle? and Lower Jurassic), and of the Molteno beds with the Kota-Maleri series of India and the Wianamatta series of New South Wales (Rhætic).

Prof. A. Young described a remarkable case of an artesian well in the Karroo which shows a daily fluctuation in its discharge. The curve obtained during some weeks by a self-recording apparatus is very regular, and has a period of almost exactly $12\frac{1}{2}$ hours. The amplitude shows a marked variation, corresponding in time with the phases of the moon, and analogous to marine spring and neap tides. The outlet is more than 2700 feet above sea-level, and the author suggests that the water, which contains a large amount of inflammable gas, is forced up from a great depth through fissures by the pressure of natural gas, and that the observed fluctuation is a minor effect, due to the moon, superimposed on the effect of the constant gas-pressure. The phenomenon is scarcely affected by barometric changes.

At a joint meeting with the Geographical Section on the second day, Mr. H. C. Schunke-Hollway gave an account of the physical geography of Cape Colony. Mr. Rogers read a paper on Glacial periods in South Africa, in which he described the glacial deposits of Table Mountain Sandstone- (Silurian?) and of Dwyka- (Carboniferous) age, each formed of materials derived from the north. There is no satisfactory evidence of glacial action in later times, the glaciated forms of certain hills in Griqualand West, cited by Stow, being now known to have been produced at any rate not later than Dwyka times, since similar forms may be traced underneath the surrounding Dwyka conglomerate. They have been preserved by a thick covering of Dwyka and other beds, which have only recently been removed.

Prof. A. Penck (Vienna) contributed a paper on changes of climate as shown by variations of the snow-line and upper tree-limit since Tertiary times, in which, from a consideration of the geological evidence as to the relative height of the snow-line and tree-line in Glacial times, he drew conclusions as to the cause of the glacial conditions. The facts pointed to a lowering of temperature as the cause of the glaciation rather than to an increase of precipitation. Prof. Penck suggested that an examination of the higher parts of the Drakensberg might probably reveal traces of a Pleistocene Ice age in South Africa, though hitherto satisfactory evidence of this has been wanting.

Prof. W. M. Davis, of Harvard, brought forward evidence for the sculpture of mountains by glaciers.[1] He based his arguments principally upon the marked difference in form between valleys proved in other ways (*e.g.* by the presence of striations) to have been once glaciated, and those which have not been glaciated, the differences being in nature and distribution such as glaciers would cause on the assumption that they could erode.

Papers were also read by Prof. Sollas, on the continent of Africa in relation to the physical history of the earth; by Prof. J. Milne, on recent advances in seismology; by Mr. E. H. L. Schwarz, on "Baviaan's Kloof, a Contribution to the Study of Mountain Folds"; and by Mr. H. T. Ferrar, on the geology of South Victoria Land, giving the results of his observations on Antarctic rocks and glaciers made during the voyage of the *Discovery*.

Prof. Sollas sketched a possible way in which the present distribution of oceans and continents on the globe may have arisen. The earth is not strictly a spheroid, but resembles an ellipsoid, of which the shortest axis passes through the poles, while the longest lies in the plane of the equator and emerges in Central Africa. The distribution of land and water is such as would obtain if the earth had the form of a pear which had been somewhat compressed in the direction of its core, and thereby caused to bulge laterally. Africa would be situated on the broad end of the pear, and would represent the remains of the primeval continent—a supposition consistent with the known absence of marine sediments over the greater part of the interior, notwithstanding the thick accumulations of flat-bedded strata existing there.

Mr. Schwarz's paper contained an account of a remarkable piece of geological structure observed in the valley of the Baviaan's River, a tributary of the Gamtoos River, in the neighbourhood of Port Elizabeth. On the Baviaan's River occur certain outliers of Enon conglomerate (Cretaceous) which have been found by bore-holes to occupy steep-sided, basin-shaped depressions with no outlet, in Palæozoic rocks of the Bokkeveld and Witteberg series (Cape system). The basins are bounded by faults or steep dip-slopes, and are explained as having been formed by two series of cross-foldings trending E.S.E. to W.N.W. and N.E. to S.W., which took place while the country was covered with the Enon conglomerate, the latter being faulted down upwards of 1000 feet. The author objects to the usual explanation of rock-folding as produced by a direct tangential thrust against an obstacle, caused by shrinkage of the earth's crust, and suggests that it may in fact be gradually produced by earthquake-waves travelling through one kind of rock (say sedimentary beds resting on granite) and encountering a mass of rock having a different modulus of elasticity (as, for example, a boss of the underlying granite). The effect of this would be to heap up the strata in folds against the obstacle, somewhat as when waves break on the shore.

At Johannesburg a considerable number of the papers were, appropriately, of mineralogical and petrographical interest.

The proceedings opened with the delivery of the presidential address by Prof. Miers (Nature, August 24, vol. lxxii. p. 405).

Prof. J. W. Gregory followed with two papers of special interest to gold miners. In one of these, on the Rhodesian Banket, he stated that he had found during a recent examination of the district that the name had been applied to several different rocks which are locally auriferous—not only to an undoubtedly sedimentary conglomerate forming the main mass of the material, but also to crush-conglomerates and breccias, and to a diorite dyke with segregations of amphibolite. The Rhodesian conglomerate may probably be rightly called Banket, but differs considerably from the Banket of the Rand in its fluviatile origin, the greater variety in size and composition of the pebbles, and its probably greater age. The question as to the right of the Rhodesian deposit to the name of "Banket" aroused considerable discussion.

In his second paper (on the Indicators of the goldfield of Ballarat—a study in the formation of gold pockets) Prof. Gregory showed the secondary origin of the so-called "indicators," or thin iron-stained bands, which traverse the slaty country-rock of Ballarat and lead to rich pockets of gold at the points where they intersect the otherwise barren quartz reefs. The indicators are shown by microscopic and field evidence to be narrow seams of chlorite or rutile needles, which are not quite, though, as a rule, nearly, parallel to the bedding, and cannot therefore be of sedimentary origin.

Prof. R. Beck, of Freiberg, gave a summary of recent investigations on the origin of pegmatites as products of the crystallisation of the residual mother liquors of a solidified plutonic magma. Certain ore-veins have been formed thus as metalliferous pegmatites, for example the tin veins of Zinnwald and Embabaan, the copper ores of Telemarken and the auriferous quartz-reefs of Berezowsk, the Yukon district and Passagem, and other places in Brazil. The presence of tourmaline in certain gold-quartzes bears out this view of their origin.

Prof. A. P. Coleman, of Toronto, dealt with the magmatic segregation of sulphide ores. The recent complete mapping of the eruptive sheet with which the nickel-ore deposits of Sudbury (Ontario) are all connected, shows that the Sudbury ore is, like the pyrrhotite nickel ores of Norway described by Vogt, really a product of segregation from the rock, of which it forms an integral part with every gradation between ore and rock. Gravitation has probably played a large part in the segregation process.

Prof. Grenville A. J. Cole read a paper on marginal phenomena of granite domes, in which he upheld the view that banded gneissic rocks are due rather to the incorporation of the surrounding rocks with the materials of an invading granite than to simple dynamic metamorphism; the banding is produced by igneous flow, and is especially marked in cases where the absorbed rocks were sedimentary or already foliated.

On the second day Mr. G. W. Lamplugh gave his report of a journey, made under the auspices of the association to examine the zigzag gorge of the Zambesi

[1] The papers by Prof. Penck and Prof. Davis will be published shortly in the *Geographical Journal*.

below the Victoria Falls, from which he had just returned. Mr. Lamplugh, who penetrated down stream for a distance of 70 miles from the Falls, accepts and confirms the explanation given by Mr. Molyneux, of Bulawayo, who attributes the zigzags to the guidance of the stream-erosion by transverse joints in the basalt plateau through which the gorge has been cut.

Prof. Penck read a paper, illustrated by a fine series of lantern slides, on the Glacial deposits of the Alps.

Mr. Kynaston, director of the Geological Survey of the Transvaal, gave an account of the recent work of the survey. Since its re-organisation in 1903, the attention of the survey has been chiefly occupied with the later formations forming the central portion of the country, and the results obtained bear testimony to the able way in which the work has been carried on. The igneous complex of the Bushveld to the north of Pretoria may be mentioned as forming an interesting petrographical province. It illustrates the differentiation of a magma, in what is probably an enormous laccolite, intruded between the Pretoria and Waterberg series, into zones of increasing basicity, ranging from the red granite of the central region to the norites, pyroxenites, serpentine, and magnetite-rock of the margin.

Dr. F. H. Hatch explained the views arrived at by Dr. Corstorphine and himself as to the correlation between the pre-Karroo beds of the Transvaal and those of Cape Colony ("Geology of South Africa," 1905). Dr. Hatch also exhibited an instrument, devised by Mr. Oehmen, for surveying bore-holes, that is, for determining the amount and direction of the inclination of the bore-hole to the vertical at any given depth—a problem of considerable importance in a country where diamond drilling is so largely used as in South Africa, as a deep bore-hole may deviate as much as 30° or more in its lower levels.

The Rev. S. S. Dornan gave an account of his observations on the geology of Basutoland. The rocks belong to the Stormberg series, and consist of sandstones, mudstones, and shales forming the Molteno Beds and the overlying "Red Beds." Fossils are rare, but a few plant and reptile remains have been found in the former. Above the Red Beds lies the Cave Sandstone, a thick-bedded sandstone, which forms the crests of the hills and contains caves sometimes showing Bushman paintings. Reptile tracks are frequent, but few other fossils occur. The higher ridges of the Drakensberg and Maluti ranges are formed of lava-flows and intrusive sheets belonging to the volcanic series. This communication was of special interest on account of the difficulty of making observations and collecting fossils in Basutoland, as it is a native reserve, and the natives are unwilling to allow any prospecting, fearing lest they might lose their country should gold be discovered.

On the last day of the meeting Mr. C. B. Horwood read a description of the Dolomite formation, which is important as being practically the only source of underground water supply in the Transvaal. The rock is probably a deep-sea deposit, which has subsequently undergone dolomitisation in shallow water, and has lost in the process all trace of organic remains, so that its age is unknown. Mr. W. Anderson contributed a paper describing the first Tertiary rocks of marine origin which have been discovered in South Africa. These comprise sands, marls, and shales, with marine Mollusca (identified as probably of Eocene age) and Foraminifera in the upper beds, while in the lowermost shales occur numerous isolated bones of Mammalia (elephant, rhinoceros, hippopotamus, &c.), with water-worn fragments of fossil wood, and fish and crustacean remains. The beds, which are confined to the coast of Natal and Zululand, are probably of estuarine origin. A calcareous grit, forming the Bluff at Durban, is also probably Tertiary in age.

A paper by Mr. E. T. Mellor dealt with the evidences in the Transvaal of glacial conditions in Permo-Carboniferous times, and the distribution of the glacial conglomerates forming the base of the Karroo system, which corresponds to the Dwyka conglomerate of Cape Colony. Here, as in the country to the south, the striations, as well as the nature of the boulders, point to a northerly origin. Mr. Lamplugh read a note on the occurrence of Dwyka conglomerate at Kimberley Mine.

In a paper on the diamond pipes and fissures of South Africa, Mr. H. S. Harger expressed his view that the source of the diamond lay in a zone of ultra-basic rocks—eclogites, lherzolites, and pyroxenites—in which it may be an original constituent crystallising from the magma, for it has been frequently found in garnets and more rarely in olivine, and has been produced artificially in the latter. The blue ground filling the diamond pipes and the associated fissures is an altered breccia formed by the shattering of these ultra-basic diamondiferous rocks during a period of volcanic activity, probably in late Triassic or Jurassic times. Mr. Harger's paper was especially valuable as embodying the results of careful personal observations carried on through several years on the occurrence and associations of the diamond in the numerous mines scattered up and down the country, some of which are little known outside South Africa. An interesting collection of specimens of the associated minerals was on exhibition in the adjoining museum.

Papers were also communicated to the meeting by Dr. J. T. Carrick, on the geology of the West Rand; by Mr. F. P. Mennell, on the plutonic rocks and their relations to the crystalline schists; and by Mr. E. Heneage, on a consideration of the Archæan period of North America and South Africa with reference to mineral occurrences.

Apart from the papers read, a more than usual amount of interest attached this year to the geological excursions, of which a large and most interesting series were organised by Dr. Molengraaff, Prof. R. B. Young, and Mr. Rogers, to whom, with the other gentlemen who acted as leaders, the thanks of the section are especially due.

These excursions—many of which occupied several days and were on a scale hitherto unprecedented, except possibly at the Toronto meeting in 1897—afforded the members of the Geological Section a unique opportunity of seeing the most interesting features of the country under the guidance of the men by whom they had been investigated, members of the various surveys being spared for the purpose by their respective Governments.

After the meeting at Cape Town Mr. Rogers led a party through the Karroo, visiting, among much else of interest, the folded ranges of the Hex River district, and exposures of the Dwyka conglomerate (or Boulder-clay) and of the Beaufort beds which have yielded Pareiasaurus and other characteristic reptiles. While in Natal, several members visited the glaciated surfaces and overlying beds at Vryheid, under the guidance of Mr. W. Anderson, the Government geologist, and Dr. Molengraaff, formerly State geologist of the Transvaal. During the meeting in Johannesburg a number of afternoon excursions were made to the gold mines and other points of interest, while after its conclusion several more extended expeditions took place. These included one to Vereeniging, under Dr. Hatch, to examine the sandstones and coal-seams of the Ecca series, which have yielded the Glossopteris flora, and the associated beds, and to see Mr. T. N. Leslie's collections of fossil plants from the Ecca sandstone and of flint implements from the Vaal River. Another party had an opportunity of studying the norites and syenites of the Plutonic complex of the Bushveld, at the Pyramids and in the neighbourhood of the Pienaar's River, to the north of Pretoria, under Mr. Kynaston and Mr. A. L. Hall; while a third party, with Mr. Hall and Mr. Frames, visited the Duivels Kantoor, at the eastern edge of the Transvaal plateau, where the escarpment of the Black Reef series and Dolomite overlooks the floor of Archæan rocks, on the denuded surface of which they rest unconformably.

Excellent opportunities were also afforded of studying the occurrence of the diamond, both at the Premier and other Transvaal mines, under Mr. Cullinan, the chairman of the Premier Diamond Company, and Messrs. Hall, Harger, Kynaston, and Trevor, and at Kimberley through the kind offices of Mr. Gardner Williams, the chairman of De Beers.

In addition to this, there was a great deal of interest to the student of surface geology to be seen during the long train journey, among which may be mentioned the hill-country in the north of Natal, the flat and sandy bush-scenery along the line to the north, and the wonderful examples of weathering in the granite country of the Matopo Hills.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—Dr. Haldane, Fellow of New College, has been re-appointed lecturer in physiology on the nomination of the Waynflete professor. The appointment is for three years from January 1, 1906. Chemical physiology is the particular subject assigned to the lecturer.

The degree of M.A. has been conferred, by a decree of Convocation, on Dr. Schlich, secretary to the delegacy for superintending the instruction of Indian forestry students.

Cambridge.—An election to an Isaac Newton studentship will be held in the Lent term, 1906. These studentships are for the encouragement of study and research in astronomy (especially gravitational astronomy, but including other branches of astronomy and astronomical physics) and physical optics. The studentship will be tenable for the term of three years from April 15, 1906. The emolument of the student will be 200*l.* per annum. Candidates for the studentship are invited to send in their applications to the Vice-Chancellor between January 16 and 26, 1906, together with testimonials and such other evidence as to their qualifications and their proposed course of study or research as they may think fit.

An appointment to the Anthony Wilkin studentship in ethnology and archæology (*Reporter*, May 23, pp. 920–1) will be made in January, 1906. Applicants should send in their names, qualifications, and a statement of the research which they wish to undertake, to the Vice-Chancellor before January 1, 1906.

Mr. T. S. P. Strangeways, of St. John's College, has been re-appointed demonstrator of pathology for a period of five years from Michaelmas, 1905.

Prof. C. S. Sherrington, F.R.S., and Prof. R. Threlfall, F.R.S., have been elected honorary fellows at Gonville and Caius College.

The State Medicine Syndicate has nominated Mr. J. E. Purvis, Mr. G. H. F. Nuttall, Dr. J. Lane Notter, Dr. R. D. Sweeting, and Dr. A. Newsholme to be examiners in State medicine in the year 1906; and Mr. G. H. F. Nuttall, Mr. C. W. Daniels, and Prof. Ronald Ross, C.B., F.R.S., to be examiners for the diploma in tropical medicine and hygiene in the year 1906.

Dr. W. A. Bone, F.R.S., has been appointed professor of applied chemistry (fuel and metallurgy) in the University of Leeds.

Mr. Charles W. E. Leigh, formerly of the Natural History Museum, South Kensington, and late assistant secretary and librarian to the Manchester Literary and Philosophical Society, has been appointed librarian of the University of Manchester.

The following appointments, *Science* states, have been made in the faculties of the George Washington University:—General Henry L. Abbott, U.S.A., to be professor of hydraulic engineering; Dr. Edward B. Rosa to be professor of physics; and Brigadier-General George M. Sternberg, U.S.A., to be professor of preventive medicine.

We learn from *Science* that President Eliot, of Harvard University, has received a letter from President Pritchett, of the Massachusetts Institute of Technology, communicating the fact that, in view of the recent decision of the Supreme Court of the State in the case of John Wilson and others *v.* the Massachusetts Institute of Technology, the corporation of the institute find it impossible to proceed with the plan of cooperation between the university and the institute which has been under consideration for the past six months. The committee appointed by the Harvard board at the request of the institute has consequently been discharged.

At the annual general meeting of members of the Bedford College for Women, held on November 17, the chairman, the Right Hon. A. H. Dyke Acland, announced that the Parliamentary grant to Bedford College had for the current session been increased from 2000*l.* to 4000*l.* It was also reported that past students had already contributed 3500*l.* to the building fund. Principal T. G. Foster, of University College, and Lady Lockyer have been elected members of the council, as representatives of the senate of the University of London. The council offers two open scholarships of the value of 20*l.* each for one year for the course of secondary training beginning in January, 1906. The scholarships will be awarded to the best candidates holding a degree or equivalent in arts or science. Applications should reach the head of the training department not later than Monday, December 18.

Sir W. H. Preece distributed the prizes and certificates to the students of Birkbeck College on November 14, and afterwards delivered an address on the simplicity of science. Sir William Preece said he has never believed that in scientific and technical training Englishmen are far behind the rest of the world. However lacking we may have been in the upper regions of higher education, we have never failed to encourage education in other ranges, and Birkbeck College was one of the first in this country to spread the love of science and to offer educational facilities to those willing to use them in their leisure hours. What is wanted now, he continued, is that men who make fortunes in the metropolis shall become patriotic founders of endowments for enabling us to distribute the teaching advantages already existing to all classes of society. Sir W. Preece incidentally remarked on the absence of memorials to pioneers of science, mentioning especially Sir Henry Bessemer—an old student of Birkbeck College. Towards the conclusion of his address he suggested that Members of Parliament, before being permitted to legislate, should have to go through a course of instruction in scientific modes of thought.

At a dinner given by the Society of Apothecaries on November 14, Mr. John Tweedy, president of the Royal College of Surgeons, responding to the toast "The Royal Colleges of Physicians and Surgeons," dealt with the subject of medical education. He said that, in accordance with the promptings of the General Medical Council, the Royal College of Surgeons has raised the standard of general education of medical students, and has increased the multiplicity and severity of the examinations. But Mr. Tweedy would like to see the wheel turned back a little. He thinks that too much is being attempted in the way of examinations, and desires to see steps taken in the direction of simplification, without any sacrifice of efficiency. If some of the restrictions and regulations were relaxed, he believes a better class of practitioner than is possible under the present *régime* could be produced. The student is over-taught, over-examined, so that he has no time to reflect, to exercise his reason or his intellect. Mr. Tweedy believes that the medical examinations are best entrusted to professional corporations. Although he does not go so far as to advocate deprivation of the universities' power of granting qualifying degrees, he pointed out that the universities do not possess a qualifying degree in law.

SOCIETIES AND ACADEMIES.

London.

Royal Society, July 29.—"Studies on Enzyme Action. VII.—The Synthetic Action of Acids contrasted with that of Enzymes. Synthesis of Maltose and Isomaltose." By E. Frankland **Armstrong**. Communicated by Prof. H. E. Armstrong.

The belief has grown up of late years that the enzymes which are capable of inducing the hydrolysis of di-saccharides or bioses act reversibly; as yet, however, but little has been done to define the theory of the process, and no understanding has been arrived at as to the limitations to which such changes are subject. The same is true of the action of acids, which also act reversibly under certain conditions.

The key to the interpretation of the changes which attend condensation must be looked for in the behaviour of glucose itself in solution.

The term glucose, in fact, has a double connotation, and these two substances must usually be thought of under the single name. As crystallised from alcohol, it consists almost entirely of the α-form; but this changes over into the β-form if maintained during several days at about 105°. If either form be dissolved in water, change takes place of the one into the other; ultimately, the two forms

exist in solution in equilibrium, in proportions which depend on the conditions, the β-compound predominating. Change takes place in a similar manner in other media.

The process by which a monose is converted into a biose must be regarded as precisely similar to that by which α-glucose and β-glucose are converted into the two methylglucosides: the behaviour of maltose, in fact, is such as to characterise it unquestionably as glucose-α-glucoside; isomaltose is presumably the stereoisomeric glucose-β-glucoside.

When glucose undergoes condensation "uncontrolled," it should give rise to both maltose and isomaltose, the proportions of which ultimately present in equilibrium would depend on their relative stability under the conditions operative at the time. But, inasmuch as hydrolysis under the influence of enzymes is an absolutely selective process, being so controlled that it takes place in one direction only, it might be supposed that synthesis under their influence would also be a controlled operation, and that the tendency of the enzyme would be to reproduce the biose which it hydrolyses: apparently this point of view was present in Croft Hill's mind and led him to suppose, at first, that maltose was the actual product; as a matter of fact, it is uncertain at present whether maltose is produced at all: it is certainly not the sole or even the predominant product.

The formation under the influence of the enzyme of a single biose, *isomeric with that which it hydrolyses*, could be accounted for on the assumption that both are produced initially, but that the one again undergoes hydrolysis as soon as it is formed, so that it all but disappears.

Proof is given in the present communication that when the condensation is effected under laboratory conditions the action takes place in the manner indicated above; in other words, the two products required by theory are both formed. Evidence is adduced to show that isomaltose is the β-glucoside correlative with the α-glucoside maltose. Experiments are described bearing on the formation of isomaltose by the agency of the α-enzyme maltase and of its correlative maltose by the agency of the β-enzyme emulsin which leave little doubt that the two bioses are producible from glucose. Whilst it is left undecided whether maltase can give rise to maltose, evidence is cited which at least renders it probable that emulsin does not give rise to isomaltose.

"Studies on Enzyme Action.—Lipase." By Henry E. **Armstrong**, F.R.S.

The study of vegetable lipase is of special importance, as the ordinary fats which are hydrolysed under its influence with peculiar readiness—are not asymmetric material but simply glycerides of acids of the acetic or oleic series. The interest of the inquiry is enhanced by the fact that animal lipase, according to Dakin, acts selectively but the selective effect of lipase is of a different order from that displayed, for example, by an enzyme of the sucroclastic class, which can only attack one member of a pair of enantiomorphous isomerides.

In the course of the experiments, Connstein's contention has been confirmed that the presence of acid is necessary to condition the hydrolysis and that practically any acid is effective provided a sufficient amount be used. Aspartic and glutamic acids—which are formed at an early stage of the germination of seeds—were found to be highly active; glycin and asparagin, however, were practically without effect.

All attempts resulted in failure which were made to obtain an extract containing an enzyme, whether from the freshly-ground material directly or after this had been deprived of the fatty matter and whether or no acid were present. Apparently, acids do not act merely by liberating the enzyme.

The Ricinus enzyme has been found to have but little action, not only on ethylic butyrate, on acetin and on dimethylic tartrate and racemate but also on ethylic mandelate, which, according to Dakin, is readily attacked by animal lipase.

It is difficult to resist the impression that the differences observed are not merely consequences of differences in stability of the various ethereal salts but that the Ricinus enzyme is possessed of properties which make it specifically capable of promoting the hydrolysis of glycerides of the higher fatty acids.

Received August 10.—"Fertility in Scottish Sheep." By Dr. F. H. A. **Marshall**. Communicated by Prof. E. A. Schafer, F.R.S.

Received August 18.—"The Pressure of Explosions. Experiments on Solid and Gaseous Explosives." Parts i. and ii. By J. E. **Petavel**.

Part i. deals with the methods and apparatus used in the research. Part ii. is devoted to a study of the properties of cordite.

Received September 7.—"On the Nature of the Galvanotropic Irritability of Roots." By Dr. Alfred J. **Ewart** and Jessie S. **Bayliss**. Communicated by Francis Darwin, For.Sec.R.S.

After the contradictory experiments of Müller-Hettlingen, and Elfving, Brünchorst found that strong currents produced a positive, and weak currents a negative, curvature. Roots hence appeared to possess a parallelotropic irritability to electrical currents, reversible according to the intensity, as in the case of heliotactic and heliotropic irritability. The experiments were not altogether satisfactory, nor did they reveal the mode of stimulation, so further investigations seemed desirable.

These have shown that the curvatures are produced by the acid and alkaline products of electrolysis liberated on opposite sides of the root. The acid products are more effective than the alkaline, so that when the current is led transversely through the subapical sensitive region the curvature always takes place towards the positive electrode; but if one electrode is placed upon the hypocotyl and the other on the irritable zone, the curvature is always towards the latter electrode, whether it be positive or negative. These *galvanogenic* curvatures are hence chemotropic in origin, as has been shown by direct experiments with acids and alkalis. Thus, if the roots are imbedded at varying distances in gelatin through which a current is passed, the roots curve in regular order towards the electrodes shortly after the acid or alkali, as evidenced by phenolphthalein, has diffused near to them.

In addition, the application of the electrolysed region of a root or of filter paper moistened with decinormal acid or alkali produces similar curvatures.

All these curvatures have been produced on a klinostat and without any injury to the root. Indeed, in many cases a constant current of 0·000009 of an ampere is sufficient to cause a curvature. Using non-polarisable electrodes, no response is given unless very strong currents are used, since the stimulation is now dependent upon the restricted internal polarisation in the root.

It is doubtful whether the electrical currents in the soil call this special irritability regularly into play. The power of curving towards faintly acid or alkaline regions must aid the root greatly in reaching soil where soluble constituents are most likely to be abundant, or where anaërobic nitrogenous decomposition (with a production of ammonia) or the subsequent aërobic nitrification (with a production of traces of nitrous and nitric acids) are in progress.

The non-development of any power of curving away from strong acid or alkali is to be explained by the non-occurrence of high local concentrations in normal soil. Even when a strong local acidity or alkalinity is artificially produced in the soil, the roots are killed before they can curve away from it, and even if the apical zone did curve away, the non-curving zone behind would be rapidly killed.

Sociological Society, October 24.—Sir John Cockburn in the chair.—Biological foundations of sociology: Dr. G. Archdall **Reid**. The author outlined modern teaching on the subject of heredity, accepting the Weissmannian conclusion regarding the non-inheritance of acquired characters. These principles he applied to human qualities with especial reference to the possibilities of selective breeding. Four main conclusions were reached:—(*a*) That there is a confusion, in popular and in uncritical medical opinion, of variation with acquirement. Many individual acquirements are considered innate. (*b*) That racial

change through heredity is a process requiring very long periods of time, so increase of natural ability by selection of variations must remain, on the whole, inconsiderable. (*c*) That the more important factor is individual acquirement or education. The great output of genius during the Athenian and Renaissance periods is to be explained, not in terms of natural ability, but as arising from exceptional opportunity. (*d*) That the one practicable method of improving the racial average of natural ability is by the elimination of clearly degenerate types.

Challenger Society, October 25.—Mr. F. W. L. Holt in the chair.—Charts illustrating the physical conditions in the English Channel during 1903 and 1904: Dr. E. J. **Allen** and D. J. **Matthews.** The observations, which were conducted from the Plymouth laboratory of the Marine Biological Association as a centre, had been made by the association's steamers *Huxley* and *Oithona*, by ocean-going liners and cross-Channel steamers, and at lightships and lighthouses. They extended from about Dungeness to Cape Finisterre, and showed the north-easterly movement of oceanic water of high salinity and temperature, the southerly movement of water of low salinity from the Irish Sea, and the varying effects of these movements on the waters of the English Channel in different months.

Royal Astronomical Society, November 10.—Mr. W. H. Maw, president, in the chair.—Observations of the sixth and seventh satellites of Jupiter, from photographs taken at the Royal Observatory, Greenwich, with the 30-inch reflector of the Thompson equatorial: **Astronomer Royal.** The photographs were shown on the screen, with diagrams to illustrate the orbits of the satellites.—Observations of the satellite of Neptune, from photographs taken at the Royal Observatory, Greenwich, with the 26-inch refractor: **Astronomer Royal.**—Expedition to Vinaroz, on the east coast of Spain, to observe the total solar eclipse of August last: Father **Cortie.**—Eclipse expedition to Burgos: Mr. **Thwaites.**—Eclipse expedition to Labrador: Mr. **Maunder.**—Photograph of the partial phase of the recent eclipse showing distinctly the entire disc of the moon: Mr. **Saunder.**—(1) Secular acceleration of the earth's orbital motion; (2) Ptolemaic eclipses of the moon as recorded in the Almagest: Mr. **Cowell.** In a paper already printed the author showed that the ancient solar eclipses are satisfied by adopting the following secular terms:—(1) in the distance of the moon from the node $+4''.4$, and (2) in the distance of the moon from the sun $+6''.8$. He now showed that these conclusjons are supported by the eclipses of the moon as given in the Almagest. Mr. Cowell considered that a secular acceleration of the earth's orbital motion does not contravene gravitational theory, as Prof. Newcomb had suggested, since it might be ascribed to the resistance of the ether.—Other papers were taken as read.

Physical Society, November 10.—Dr. C. Chree, F.R.S., vice-president, in the chair.—The question of temperature and efficiency of thermal radiation: J. **Swinburne.** It has long been known that various surfaces have different emissivities, and it is generally held that at a given temperature some bodies radiate a larger percentage of their total radiation in the form of light. This view is largely based on some experiments by Evans and Bottomley, both of whom, the author remarks, make the same slip in confusing difference of emissivity with difference of efficiency at the same temperature. It is urged that a body A at the same temperature as B cannot give out radiation corresponding to a higher temperature of B, for if it could, and A and B were enclosed in a perfectly reflecting space, A would heat B to a higher temperature than A.—Note on constant-deviation prisms: T. H. **Blakesley.** It appears that any prism of three faces can be made to give a spectrum in which the light, that occupies the centre of the field of view of the telescope at any moment, has undergone passage through the two refracting surfaces of the prism in such a way that its original angle of incidence is equal to its final angle of emergence. This condition, which in the ordinary employment of the prism is associated with minimum deviation, must be described as isogonal passage, the property which has the minimum value being not the deviation, but the rate of passage across the field of view for a given motion of the prism, to which alone in these instruments motion has to be given to bring different parts of the spectrum into the field, the telescope and collimator both remaining fixed. If any triangle having the angles α, β, γ is adopted as the shape of a prism, the telescope must be set to make one of these angles, say γ, with the line of the collimator. Then the prism being placed in the region between them, a position can be found so that any ray selected will be refracted through one of the sides containing the angle γ, reflected at the side opposite γ, and finally refracted through the remaining side containing γ. On emergence it will be parallel to the telescope, and its passage through the refracting faces will be isogonal. The prism will affect the light to the same degree as one used in the ordinary way, of refracting angle $\beta-\alpha$, would do. The sine of the angle of original incidence is equal to $\mu . \sin(\beta-\alpha)/2$ for every ray occupying the centre of the field of view. If the prism is turned over, but the same angle γ employed, the telescope will remain unaltered, but the spectrum will run in an opposite direction to the first. Mr. Blakesley showed the case of two prisms in which the spectra ran in different directions. The top prism was slightly tilted by the insertion of a small piece of silver paper between the prisms. By this means one of the spectra was shifted upwards by a small amount, and one could see in the telescope a band, at top and bottom, of the component colours, and in the centre a band of the resulting colours. It was suggested that spectroscopes on this plan could be advantageously employed in measuring the motion in the line of sight of heavenly bodies, as a line brought into coincidence with itself for a terrestrial source in the two spectra would, in the case of such motion, split up into two moving *different* ways in the field of view. It was also explained how such prisms could be placed in trains for increased dispersion.

Royal Meteorological Society, November 15.—Mr. Richard Bentley, president, in the chair.—The rainstorm of August 24 to 26 in counties Dublin and Wicklow: Sir John W. **Moore.** The atmospheric disturbance which caused the torrential rainfall was near the shores of Kerry and Cornwall on August 24, and the next morning it was near the Scilly Islands. Thence it travelled slowly northwards up St. George's Channel, its centre passing near Dublin early on the morning of August 26. At this time the system suddenly changed its course, crossing the channel eastwards to Wales, and finally passing over central England and out to sea at the mouth of the Humber in a north-easterly direction. It appears that the rainfall on August 25 exceeded 3 inches at all stations in the counties Dublin and Wicklow, while it rose above 4 inches, and even 5 inches, at stations near the Dublin and Wicklow mountains. Sir John Moore is of opinion that this remarkable downpour was brought about by the cooperation of the following factors:—(1) a chill antecedent to the arrival of the rain-bearing depression; (2) the slow progress of the depression; (3) the fact that the counties Wicklow and Dublin lay to the westward of the cyclonic centre, and so received its north-easterly and northerly winds; and (4) the physical configuration of those counties and their coast line. As the result of this remarkable rainstorm a destructive flood occurred over the low-lying parts of the Bray urban district near the mouth of the Bray River. At Little Bray the water rose to a height of 4 feet in the streets, flooding houses, destroying domestic animals and fowls, wrecking furniture, and covering floors, yards, and gardens with a thick alluvial deposit.—The aquameter: Dr. W. B. **Newton.** This is a new instrument for measuring accurately the amount of aqueous vapour present in the atmosphere.

Paris.

Academy of Sciences, November 13.—M. Troost in the chair.—Nitrates and nitrites as manure: Th. **Schlœsing,** jun. Nitrate of calcium is now produced by electrical means from the air, and the salt thus obtained contains nitrite. It was desirable to ascertain whether the calcium nitrate is equivalent for manurial purposes to the sodium nitrate in ordinary use, and also whether the nitrite was in any way prejudicial. Cultivation experiments showed that the two nitrates were equivalent, and that the presence

of nitrite was without objection.—On the floating spiked Decapods collected by the American expeditions of the *Hassler* and the *Blake*: E. L. **Bouvier.**—On the congruences of skew cubics: M. **Stuyvaert.**—On the development of a uniform analytical function in an infinite product: M. **Zoretti.**—On the complementary geodesic triangulations of the upper regions of the French Alps (third expedition): P. **Helbronner.**—On a dynamometric brake designed for measuring the power of motors, and which allows of the utilisation, in an electrical form, of the greater part of the work developed: A. **Krebs.** This electrical brake has been successfully applied to measuring the horse-power of motor-car engines of from 1 horse-power to 200 horse-power. It has several advantages over the friction dynamometer, as it can be used as long as may be required without any danger of over-heating, and is not liable to the errors introduced by the variations in the coefficient of friction.—On the electrical phenomenon created in liquid chains, symmetrical as regards concentration, by the formation of a fresh surface of contact: H. **Chanoz.**—On the liquefaction of air by compression with external work: Georges **Claude.** A continuation of an earlier paper on the same subject, and giving an account of the modifications which it has been necessary to make in the arrangements of the apparatus to secure an increased yield of liquid air.—On the molecular conductivity of the phosphoric esters: P. **Carré.** Measurements are given for the monoalkylphosphoric esters derived from ethyl and isobutyl alcohols, glycerol, erythritol, and mannide, and it was found that the ionisation of the acid phosphoric esters is considerably greater than with phosphoric acid itself.—A general method for the synthesis of $\alpha\beta$-glycidic esters and of ketones: Georges **Darzens.** In a previous paper the author has shown that by the condensation of monochloroacetic acid with ketones, trisubstituted glycidic esters are formed by the saponification of which unstable acids are produced, the latter readily splitting up into carbon dioxide and a ketone. This reaction has now been extended to α-chloropropionic acid, giving ketones of the type $RR_1.CH-CO-CH_3$. The reaction appears to be quite general; eight new glycidic esters and five new ketones are described.—On the constitution of crystallised bodies: Fréd. **Wallerant.**—Observations relating to the morphology of aërial bulbs: Marcel **Dubard.** *Coleus Dazo* shows a tendency to accumulate its reserves in its aërial organs when the conditions of growth are unfavourable to the formation of subterranean stems. These reserves, of a starchy nature, are deposited in the axillary buds originally intended to form flowers.—The changes in the amount of fragrant oil present in the plant during the accomplishment of the functions of the flower: Eug. **Charabot** and Alex. **Hébert.**—Comparison of the cycles of evolution of the Orthonectidæ and Dicyemidæ: F. **Mesnil** and M. **Caullery.**—The formation of the vitellus in the sparrow: M. **Dubuisson.**—The embryogeny of the Hexactinidæ: L. **Faurot.**—The reason why certain deaf mutes can hear low notes better than high ones: M. **Marage.** From experiments on animals unprovided with any organ of hearing, the author concludes that the perception of low musical notes by deaf mutes is not hearing in the proper sense of the word, but a special sense for low notes which is also met with in the lower animals. The increase in the activity of the pancreatic secretion by calcium salts: C. **Delezenne.** The experiments described show the importance of calcium salts in developing the activity of pancreatic juice. A complete explanation of the effects produced is not, as yet, forthcoming.—On the tectonic at the S.W. of Chott and Hodna: J. **Savornin.**—On the use of hydrostatic pressure in tapping thermal springs: L. **De Launay.**—The exploration of the free atmosphere above the Atlantic Ocean, north of the tropical regions, on board the yacht of the Prince of Monaco, in 1905: H. **Hergesell.**

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 23.

ROYAL SOCIETY, at 4.30.—On the Nature of the Galvanotropic Irritability of Roots: Dr. A. J. Ewart and Miss Bayliss.—Some Observations on *Welwitschia mirabilis*, Hooker-f.: Prof. H. H. W. Pearson.—On the Effects of Alkalies and Acids, and of Alkaline and Acid Salts, upon Growth and Cell Division in the Fertilised Eggs of *Echinus esculentus*; a Study in Relationship to the Causation of Malignant Disease: Prof. B. Moore, Dr. H. E. Roaf, and E. Whitley.—A Note on the Effect of Acid, Alkali, and Certain Indicators in Arresting or Otherwise Influencing the Development of the Eggs of *Pleuronectes platessa* and *Echinus esculentus*: E. Whitley.—On Certain Physical and Chemical Properties of Solutions of Chloroform and other Anæsthetics. A Contribution to the Chemistry of Anæsthesia. (Second Communication): Prof. B. Moore and Dr H. E. Roaf.—(1) On the Possibility of Determining the Presence or Absence of Tubercular Infection by the Examination of a Patient's Blood or Tissue Fluids: (2) On Spontaneous Phagocytosis and on the Phagocytosis which is obtained with the Heated Serum of Patients who have responded to Tubercular Infection, or as the Case may be to the Inoculation of a Tubercle Vaccine: Dr. A E Wright and Staff-Surgeon S. T Reid, R.N.—On the Occurrence of the Heterotypical Mitosis in Cancer: Dr. E. F. Bashford and J. A. Murray.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Applications of Electricity in the Royal Gun Factory, Woolwich Arsenal: Colonel H. C. L. Holden, R.A., F.R.S.

FRIDAY, NOVEMBER 24.

PHYSICAL SOCIETY, at 5.—The Dielectric Strength of Air: A. Russell.—On the Electrical Conductivity of Flames containing Salt Vapours for Rapidly Alternating Currents: Dr. H. A. Wilson.—On the Lateral Vibration of Loaded and Unloaded Bars: J. Morrow.

SATURDAY, NOVEMBER 25.

THE ESSEX FIELD CLUB (at Essex Museum of Natural History, Stratford), at 6.30.—Report of Club's Delegate at Meeting of Corresponding Societies' Committee, British Association, 1905: F. W. Rudler, I.S.O.—Romance of Plant Life: F. Martin-Duncan.

MONDAY, NOVEMBER 27.

SOCIETY OF ARTS, at 8.—The Measurement of High Frequency Currents and Electric Waves; Prof. J. A. Fleming, F.R.S.

INSTITUTE OF ACTUARIES, at 5.—Valuation by Select Tables: Separate Papers by Messrs. T. G. Ackland, O. F. Diver and G. King.

TUESDAY, NOVEMBER 28.

ZOOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Discussion*: On Waterways in Great Britain: J. A. Saner.—*Also, time permitting*: The Steam-Turbine: The Hon. C. A. Parsons, C B., F.R.S., and G. G. Stoney.

WEDNESDAY, NOVEMBER 29.

SOCIETY OF ARTS, at 8.—The British Association in South Africa: Sir William H. Preece, K.C.B., F.R.S.

FRIDAY, DECEMBER 1.

INSTITUTION OF CIVIL ENGINEERS, at 8.—An Installation for the Bacterial Treatment of Sewage, at Neath: W. L. Jenkins.

LAGUERRE'S MATHEMATICAL PAPERS.

Œuvres de Laguerre. Tome ii. Pp. 715. (Paris: Gauthier-Villars, 1905.) Price 22 francs.

THE publication of the mathematical papers of Laguerre, undertaken after his death in 1886 by MM. Hermite, Poincaré, and Rouché under the auspices of the Academy of Sciences, has at length been completed. A first volume, to which M. Poincaré contributed as a preface an admirable appreciation of the author, appeared in 1898; and now some eighty papers which treat of geometrical subjects have been collected from the various scientific journals and reprinted in a second and final volume of more than 700 pages. Most of these papers are of but four or five pages in length, for it was Laguerre's habit, when a mathematical investigation had aroused his interest, to return to it again and again as new ideas occurred to him; and so it comes to pass that the majority of his writings on geometry may be classified as dealing with one or other of some half-dozen wide but distinct subjects.

The discovery with which Laguerre made his entry into the ranks of original investigators is of such moment in the history of modern mathematics that we will pause in order to realise the condition of geometrical knowledge at the time, and the circumstances in which it was made. The first three of the papers now under review bear the dates 1852–3, and were written when the author, a student eighteen years of age at the Institution Barbet, was still only a candidate for admission to the École Polytechnique. It was a time when a great change in geometrical thought had been initiated. Poncelet and Chasles had begun to build up the theory of projective geometry, and through it mathematicians had been made to recognise that theorems previously regarded as wholly without connection might in reality be but different presentments of the same more fundamental fact. But the structure was as yet very far from complete; many of the chief features of the theory as we now know it were still obscure and needed explanation. It fell to Laguerre to provide the most important and prolific discovery on which modern geometrical theory has been founded, the inner meaning of angular magnitude. In the second of his three early papers was enunciated for the first time the proposition that the sides of an angle form with the two isotropic lines through the vertex a pencil the anharmonic ratio of which depends only upon the magnitude of the angle.

This was no chance discovery, lighted on by a stroke of undeserved good fortune, for the rest of the paper shows how true a grasp of the new principles Laguerre had already obtained. He goes on to point out that the proposition furnishes the solution of the problem of homographic transformation of angular relations—a problem which had baffled the founders of projective geometry—and gives many further developments and results, a special case of one of which may be cited as illustrative. The well known theorem of Menelaus concerning the ratios of the segments into which the sides of a triangle are divided by any straight line is identical with the theorem that the angles of a triangle make up two right angles; either theorem can be deduced from the other. It is regrettable that English treatises upon analytical geometry so rarely attribute theorems to their authors, for it is with this discovery, rather than any achieved later in more advanced subjects, that we should wish the name of Laguerre to be always associated. Certainly no discovery has had so far-reaching an influence upon geometrical research during the past half-century.

In the twelve years which followed Laguerre published nothing. His military duties as an officer of artillery at first absorbed him; then, having been transferred to the manufactory of arms at Mutzig, he found leisure to take up once more his favourite study; it was not, however, until 1865, after his recall to Paris to the École Polytechnique, that he published the first of the series of original papers which he continued without intermission until his death.

A large number of these are concerned with analytical geometry, and through an interesting section of them runs an idea allied to his earlier work, the use of imaginaries in geometry. Thus in one of the first papers we find a full exposition of the theory of foci as extended from conics to plane curves of any class, and the distinction is drawn between ordinary foci and singular foci of a curve which passes through the circular points. Another such matter with which Laguerre frequently occupied himself, and which seems never to have received the attention it deserves, is the means of representing in a concrete manner the points of a plane or in space the coordinates of which are complex quantities. Imaginary values of the coordinates may satisfy the equation of a curve, and are then often spoken of as the coordinates of an imaginary point on the curve; cannot geometry suggest some mode of representing these points similar to that of Argand, which plays so important a part in the theory of equations involving a single variable? No solution could be satisfactory which varied with the coordinate-system employed. Laguerre's method was to represent a pair of points the coordinates of which are conjugate complex quantities by a real segment of a line, distinguishing the two imaginary points when necessary by the sense in which the segment is measured; the ends of the segment are the intersections of the lines which join the imaginary points to the circular points. Thus the line joining two real foci of a conic represents the two imaginary foci. It now becomes feasible to express the conditions of collinearity, &c., of imaginary points by properties of their representative segments. For points in space a similar procedure is adopted; a point the coordinates of which are complex is represented by a real circle, which must be described in a definite sense.

Having extended the notion of a focus to curves other than conics, it was natural that Laguerre should study curves which possess focal properties; accord

ingly he made many investigations upon special quartic curves, both plane and twisted; he considered the meaning of a focus of a curve traced on a sphere, showing that the method of inversion changed the ordinary foci of such a curve into foci of the inverse curve; he published many investigations upon a class of loci to which at the time considerable attention was paid, anallagmatic curves and surfaces. Other papers treat of the cyclide of Dupin, the curve of intersection of two quadric surfaces, and a family of curves called by Laguerre Cassinians: and it is to be noted that while writing upon a particular curve he would at times include theorems of wider application.

A passing mention may be accorded to an interesting statement of the addition theorem of hyperelliptic functions closely resembling that derived from Poncelet's polygons in elliptic functions; to researches upon Steiner's Roman surface and its reciprocal, known as Cayley's cubic surface, and other applications of the theory of forms to geometry. Finally, at the end of the book we meet with a series of papers in which Laguerre's discovery of *geometry of direction* is developed. The idea from which this sprang is elementary enough; a straight line or a circle may be traced out by a moving point in two opposite senses, and therefore is regarded by Laguerre as composed of two "half-lines" or two cycles. The notion of tangency is modified when a curve is described in a definite direction, so that a cycle is regarded as possessing one tangent only parallel to a given half-line. Following up this thought, Laguerre is led to divide all curves into curves of direction, which can be divided analytically into two trajectories traced out in different senses, and curves which have not this property; he finds the form of the tangential equation of the most general curve of direction. By help of a highly ingenious "transformation by reciprocal half-lines," it is shown how certain problems may be greatly simplified; the problem of drawing a circle to touch three given circles, for example, is reduced to that of drawing a circle through three points. The theory is extended also to spherical geometry.

Laguerre's life-work in geometry forms a volume which no mathematician can study without being profoundly impressed by the ingenuity of the author and his skill in handling every method which he employs; papers such as his, models of clear polished style, are read with keen intellectual enjoyment. Yet when the book is laid down and we reflect on the work as a whole, there comes a regretful conviction that what has been accomplished is very far from all that could have been hoped for from the powers of the author and his brilliant first achievement. Delicate in health and of retired life, Laguerre's isolation from the march of scientific thought is betrayed in his writings. General notions appealed to him solely by their applicability to particular problems, and he therefore chose to bestow the utmost care upon a number of short discussions of special topics. Let the reader, if he would appreciate what is best in these collected writings of Laguerre, realise when he takes up the book that its author was one of those who are content to apply to small things powers capable of far higher work, and he will find matter to arouse his interest and admiration in every paper reprinted in the volume.

PHILOSOPHICAL STUDIES.

(1) *Goethe's Philosophie aus seinen Werken.* Edited with an introduction, by Max Heynacher. Pp viii+428. (Leipzig: Dürr'sche Buchhandlung. 1905.) Price 3.60 marks.

(2) *Immanuel Kant, Physische Geographie.* Second edition. Edited by Paul Gedan. Pp. xxx+386. (Leipzig: Dürr'sche Buchhandlung, 1905.) Price 2.50 marks.

(3) *Dialoge uber naturliche Religion, über Selbstmord und Unsterblichkeit der Seele.* By David Hume Translated into German and edited by Dr. F Paulsen. Third edition. Pp. 165. (Leipzig. Dürr'sche Buchhandlung, 1905.) Price 1.50 marks

(4) *Immanuel Kant's Kleinere Schriften zur Logik und Metaphysik.* Second edition. Edited by Karl Vorländer. In four parts. Pp. xxxii+169, xl+172, xx+175, xxxi+176. (Leipzig: Dürr'sche Buchhandlung, 1905.) Price 5.20 marks.

(5) *G. W. F. Hegel, Encyclopädie der philosophischen Wissenschaften im Grundrisse.* Second edition. Edited by Georg Lasson. Pp. lxxvi + 522. (Leipzig: Dürr'sche Buchhandlung, 1905.) Price 3.60 marks.

(1) GOETHE'S work was so many-sided, and withal so voluminous, that it is a real service to educated thought to have presented, as here, a volume of extracts, in moderate compass, containing in his own words an account of the great writer's philosophic and scientific views, and of the influences exerted on him by different systems. Herder, Spinoza and Kant all obviously attracted him at various times, and his name must find a place in any account of the theory of colour or of comparative anatomy—to name only two of the scientific subjects in which he was interested. With these and kindred matters the editor deals in a well-informed introduction. He knows the literature well, his Eckermann, the Goethe Jahrbuch, and Goethe's poetry. Goethe's title to be regarded as a forerunner of Darwin is duly emphasised.

(2) That Kant should thus have lined the wings of his spirit in the dregs of the sensible world will astonish the average reader, for this work condescends to minute details regarding the animal, vegetable, and mineral kingdoms, the characteristics of different races of men, and the like. Even one of the earlier parts, dealing with mathematical preliminaries, is not at all speculative in its nature, and only one or two paragraphs in the introduction, which point out that geography deals with facts in space as history with events in time, remind us of the Critique of Pure Reason; but the services of Kant to geography are not negligible, and have been attested by Helmholtz.

The present edition contains a full statement of

variant readings, and many corrections of the text due to this editor.

(3) Hume's dialogues on natural religion run on much the usual lines. The characters are three in number, Demea the representative of believing scepticism, Philo of unbelieving scepticism, and Cleanthes of conciliatory rationalism. But there is this peculiarity in Hume's treatment, that, while there is no doubt that his own standpoint is that of Philo, he has chosen to make Cleanthes the hero, and concludes his work with the opinion that Philo's principles are more probable than Demea's, but that those of Cleanthes approach still nearer to the truth. The essays on suicide and on the immortality of the soul have been preserved only by accident, as their author attempted to suppress them. The German translation and introduction are from the pen of the well known professor in Berlin, and, like everything published in this philosophical series, are excellent.

(4) This volume contains about fifteen of Kant's smaller metaphysical and logical works, some of them translated from Latin, some of them written before the birth of the "critical" philosophy, not all of them interesting or important. They range over a variety of themes, from the dreams of a spiritist (viz. Swedenborg) to the well known prize-essay on the progress of metaphysic since the time of Leibniz and Wolf. This editor's introductions to the various essays and treatises are extremely helpful and interesting.

(5) The encyclopædia, the only complete and authentic statement of Hegel's system—best known to English readers by the late Prof. Wallace's translations of its first and third parts—is here published in an excellent form. In the introduction the editor discusses (*a*) the fundamental ideas of the Hegelian philosophy; (*b*) philosophy as science; (*c*) the encyclopædia, and Hegel's relation to earlier systems.

OUR BOOK SHELF.

The Oxford Geographies. Vol. ii. The Junior Geography. By A. J. Herbertson. Pp. 288. (Oxford: Clarendon Press, 1905.) Price 2*s*.

When a school-book treats of the geography of the whole world in less than 300 pages of large, clear print, interspersed with abundant diagrams, its claim to compete with the ordinary class-book must be based on the substitution of quality for quantity, wise selection and arrangement for all-including comprehensiveness. The book before us may fairly make such a claim. There is nothing of the gazetteer about it: its method is that of connected description; in place of statistical tables we have an abundance of distribution-maps, and continents and countries are divided according to physical features more than by political boundaries. Thus in the case of England the counties are entirely ignored, and the pupil is spared the necessity of learning as many "facts" about Oxfordshire as about Lancashire. So, too, in the case of Europe, there is a special section on Alpine lands, which renders possible a connected account of the railway routes across the Alps, and should prevent the common misconception of the Alps as coextensive with the political area of Switzerland.

Nearly one-third of the book is occupied with the British Isles, and about as much with Europe, the remainder being about equally divided between Asia, Africa *plus* Australia, and America. It would be easier to form a judgment on the opening part if the "Preliminary Geography," which is intended to precede it, had been published. As it stands, this opening part, consisting of a large number of distribution-maps (orographical, climatic, industrial, &c.) of the British Isles, with a discussion of their meaning and relations, is full of suggestiveness to the enthusiastic teacher, and in his hands is capable of expansion into a course of practical geography.

In such a book the critic can, of course, find plenty of missing "facts," though we have found remarkably few of first-rate importance. Several which we failed to find in the text turned up in the maps, which is just as well in view of the importance which the author attaches to the study of maps. ("Look at the map and notice . . ." is a constantly recurring phrase.) Chicago, it is true, appears to be only casually mentioned on p. 262, without any allusion to its unique geographical position with reference to the Mississippi basin and the great lakes; and along with the trans-Alpine routes to which we have already referred we should have expected to find some account of the longitudinal route of the Orient express. While the numerous diagram-maps form one of the best features of the book, their execution is unequal, the lettering on some being indistinct and the shading sometimes amateurish. In the map of the chief North American railways the names of the lines might be given as far as possible, and the route of the projected Grand Trunk Pacific continued to Port Simpson instead of ending at Winnipeg; while in Fig. 22 it seems unnecessary to distinguish part of the Scotch coal-fields merely because the coal is of Lower Carboniferous age.

A. M. D.

Organic Evolution. By C. W. Saleeby, M.D. Pp. 124. (London and Edinburgh: T. C. and E. C. Jack, n.d.) Price 1*s*. net.

Dr. Saleeby has written a little book on a great subject, and there is much to admire in his achievement. Without technicalities and with vivacious clearness he discusses the history of the idea of organic evolution, the so-called evidences which show the validity of the evolution-formula, the conditions of evolution (heredity and variation) and the factors in the process (natural and sexual selection), the evolution of plants, the history of the horse, the past and future evolution of man. And we can get all this for a shilling! The author writes in an unconventional chatty way, and is nothing if not up to date. He seems, however, to have written in hot haste, for he makes many slips. Perhaps it does not matter much that he speaks of Alfred Russel Wallace as being in 1858 "a young surgeon," but it is hard on the whale to have it said of him that his five "fingers, hand and all, are buried deep in blubber, and serve him no purpose whatever." Surely Dr. Saleeby's teacher, Sir William Turner, to whom he gracefully refers, will be rather shocked at this libel on the whale's flipper. Perhaps it does not matter much that a certain Matthew Hay (Patrick Matthew?) is credited with having conceived the idea of natural selection in the early years of the nineteenth century, but we are somewhat baffled by being twice told that while the hen has three and a half fingers, the embryo chick has *a five-fingered hand*. If we dissect the embryo we shall see this, we are told. We do not like Dr. Saleeby's version of the lineage of extinct forms "which continuously connect the horse of to-day with a five-toed ancestor," but we object still more to the statement that "the adult or fully-developed barnacle is far inferior to the larva, for it

is little more than a fixed fleshy stalk, upon which grows the body and its shell"—"a palpable case of what we call degeneration." If all degeneration were on the lines of the barnacle's life-history, it would be difficult to distinguish it from progress. We wish there had not been these and other blemishes in this sprightly and interesting little book, for it is sure to be popular. J. A. T.

Le Chauffage des Habitations par Calorifères. By M. Raymond Périssé. Pp. 173. (Paris: Gauthier-Villars et Fils, n.d.) Price $2\frac{1}{2}$ francs.

THIS little work is of a very practical nature; and although it appeals more particularly to the engineer and architect it may be read with advantage by the general reader, for it sets out, in a manner which is clear and easily intelligible to all, the advantages which accrue from the systems of heating dwellings by the various warming apparatus which are installed, not in the living rooms, but on the ground floor or in the basement. The advantages in the use of steam, hot-water, or hot-air apparatus, instead of fireplaces or stoves, are certainly real ones; for the house is more uniformly and better heated, at a less expense, trouble, and risk, and the apartments are not encumbered with the large stoves so generally seen on the Continent.

The advantages and disadvantages of the different systems are explained, and various applications of these systems are illustrated. The reader is also told how each may be best applied and regulated to meet the variable requirements as to heat, the different circumstances of the dwelling, the conditions of occupancy, and the like.

Auslese aus meiner Unterrichts- und Vorlesungs-praxis. By Dr. Hermann Schubert. Erster Band. Pp. 240. (Leipzig: G. J. Göschen, 1905.) Price 4 marks.

TEN chapters dealing with a variety of subjects—logarithms, cyclotomy, the theory of physical dimensions, systems of circles and spheres being the most important. The principal novelty is the treatment of logarithms (pp. 1–68), fair approximations being obtained by combining inequalities such as

$$-\log m+2\log(m+1)-\log(m+2)>0.$$

The method is quite elementary and very ingenious, but it has no practical value, and strikes one as being artificial. The chapter on dimensions (reprinted from the *Naturw. Wochenschr.*, 1895) is interesting, but not convincing; its essential feature is

$$[\text{mass}]=[\text{length}]^3[\text{time}]^{-2}.$$

Pangéométrie; ou Précis de Géométrie fondée sur une Théorie générale et rigoureuse des Parallèles. By N. J. Lobatschewsky. Réimpression facsimilé conforme à l'édition originale. Pp. 279–340, and list of errata. (Paris: A. Hermann, 1905.) Price 5 francs.

LOBATSCHEWSKY shares with the Bolyais the credit of founding the theory of non-Euclidean geometry, in which Euclid's axiom of parallels is not assumed to be true. His "Pangéométrie" was communicated to the mathematical faculty of the University of Kazan in 1855 on the occasion of his jubilee; this fact might well have been indicated in the present reprint. It is the author's last and most complete exposition of his theory, and mathematicians will be glad to have it in this accessible form, though, like other similar reprints, it is rather trying to the eyesight.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Bates-Müller Hypothesis of Mimicry: a Question of Historical Accuracy.

A PAPER dealing with the above subject, by the late Dr. A. S. Packard, has just been published in the *Proceedings of the American Philosophical Society* (vol. xliii., No. 178, p. 393), in which this well known entomologist endeavours to show that the markings of organisms ("pœcilogenesis") are "due to the physical rather than to the biological environment." I must leave it to others to consider how far the late author has established his case as against Bates, Fritz Müller, and those who have accepted the theories of mimicry associated with these names. My object in asking you to give space to this letter is to point out a distinct error which, if allowed to pass unchallenged, is likely to be accepted as a true statement of Darwin's views in the sense conveyed by the American writer.

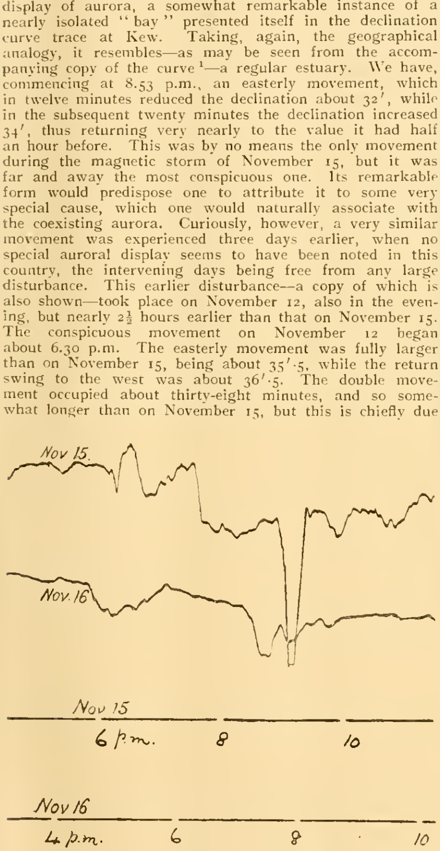
Happening to know the actual history of the Müllerian theory of mimicry through the courtesy of Mr. Darwin himself, I can assure those who read the paper that the passage which is quoted does not refer to that theory at all. In the letter to Fritz Müller referred to (August 28, 1870) Mr. Darwin says:—"I should not be at all surprised if your suggestion about sexual selection were to prove true; but it seems rather *too speculative to be introduced in my book*," &c. ("More Letters," vol. ii., p. 91). Now Dr. Packard quotes only the words which I have italicised as "Darwin's own estimate of Müller's little paper," but this is a misstatement of the facts. Darwin, it will be observed, is referring to a suggestion about sexual selection, and I am in a position to state what that suggestion was. At the date of the correspondence quoted (1870), Fritz Müller had observed the striking resemblances, or "mimicry," between butterflies belonging to "protected" groups, as, in fact, Bates had done before him. In searching for an explanation of this apparent violation of the Batesian theory, he suggested that it almost appeared as though the females of one protected species had been influenced in their choice by seeing the predominant pattern of other protected species always about them. Mr. Darwin was good enough to allow me to read Müller's letter to him, and in forwarding it to me in 1872 he added:—"You will also see in this letter a strange speculation, which I should not dare to publish, about the appreciation of certain colours being developed in those species which frequently behold other forms similarly ornamented" ("Charles Darwin," by E. B. Poulton, p. 202). This is the "suggestion about sexual selection" to which Darwin refers in his letter to Müller, and, so far as my memory serves me, I do not think this speculation was ever formally published to the scientific world.

The Müllerian theory which the late Dr. Packard considered that he had demolished was not published until 1879, the "little paper" in question having been contained in a number of *Kosmos* which Mr. Darwin forwarded to me in that year. On reading the said note I was at once convinced that Müller had found the true explanation of mimicry between protected groups, and I accordingly directed Mr. Darwin's attention to the matter and published a translation of the paper (*Proc. Ent. Soc.*, 1879, p. 20) in order to bring it under the notice of English entomologists. Writing to me in 1879 about this paper, Mr. Darwin said:—"F. Müller's view of the mutual protection was quite new to me" (Poulton, *loc. cit.*, p. 213). It is thus evident that Dr. Packard confused a tentative speculation of Müller's, which was contained only in a letter to Darwin, and probably never intended for publication, with the now well known Müllerian theory which was published formally some nine years later.

R. MELDOLA.

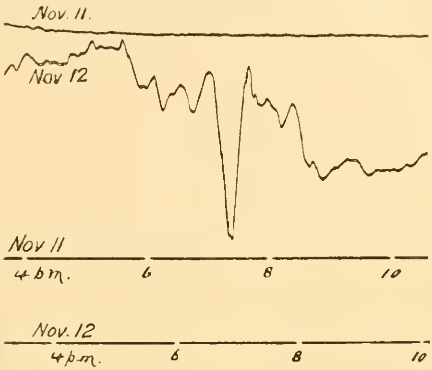
Magnetic Storms and Aurora.

IN view of the interest recently displayed in theories as to the origin of magnetic disturbances, attention may be directed to some rather curious phenomena exhibited during the magnetic storms experienced lately. Usually when a magnetic element during a storm suffers a large deviation in one direction it does not simply return to, but overshoots, its original value, and oscillates about its undisturbed position. If we liken the curve to the outline of an island on a map, a conspicuous indentation of the coast line is usually accompanied by a correspondingly pronounced promontory. Whilst this is much the more common phenomenon, it is by no means very unusual to have, as it were, an isolated bay in an otherwise straight coast line; only when this happens the "bay" seldom forms a deep indentation, and the curvature of its outline is seldom very great. On November 15, during the recent display of aurora, a somewhat remarkable instance of a nearly isolated "bay" presented itself in the declination curve trace at Kew. Taking, again, the geographical analogy, it resembles—as may be seen from the accompanying copy of the curve[1]—a regular estuary. We have, commencing at 8.53 p.m., an easterly movement, which in twelve minutes reduced the declination about 32′, while in the subsequent twenty minutes the declination increased 34′, thus returning very nearly to the value it had half an hour before. This was by no means the only movement during the magnetic storm of November 15, but it was far and away the most conspicuous one. Its remarkable form would predispose one to attribute it to some very special cause, which one would naturally associate with the coexisting aurora. Curiously, however, a very similar movement was experienced three days earlier, when no special auroral display seems to have been noted in this country, the intervening days being free from any large disturbance. This earlier disturbance—a copy of which is also shown—took place on November 12, also in the evening, but nearly $2\frac{1}{2}$ hours earlier than that on November 15. The conspicuous movement on November 12 began about 6.30 p.m. The easterly movement was fully larger than on November 15, being about 35′·5, while the return swing to the west was about 36′·5. The double movement occupied about thirty-eight minutes, and so somewhat longer than on November 15, but this is chiefly due



to the movement on November 12 beginning and ending somewhat less abruptly.

The total ranges of the declination disturbances on November 12 and 15 were respectively about 42′ and 50′. The other elements were also disturbed, the horizontal force range being approximately 200 γ on November 12 and 250 γ on November 15 ($1\gamma = 0{\cdot}00001$ C.G.S. unit). In each of these horizontal force curves there was also a prominent movement somewhat analogous to the above movements in the declination, but not synchronous with them, and with an *increase* of force. The horizontal force movement on November 12 was the more striking, the force increasing by about 180 γ in thirteen minutes, and



then falling off about 155 γ in the next thirteen minutes. On November 15 the nearest analogous movement was of a more normal character, an increase of 110 γ, occupying about ten minutes, being followed by a fall of 160 γ in the next twenty minutes. On November 12 the prominent horizontal force change was only a few minutes later than the prominent declination change, but on November 15 the most prominent horizontal force movement preceded the prominent declination movement by about $2\frac{3}{4}$ hours. There were considerable horizontal force movements at the time of the prominent declination movement on November 15, but they were of a more commonplace character. The disturbance on November 12 commenced about 9.30 a.m., terminating about midnight; that on November 15 lasted much longer, starting about 3.15 p.m., and continuing for about thirty hours.

National Physical Laboratory, November 21.

[1] Two days' curves—each with its base line—are taken on each photographic sheet; the upper is always the earlier.

Absorption Spectra of Ultra-violet Rays by Vapour and Liquids

IN connection with some letters recently published in NATURE (vol. lxxii. pp. 557, 630), the following note may perhaps have some interest. Researches on the above named subject have been made in the physical institute of the University of Erlangen. Dr. Pauer (*Wied. Ann.*, lxi., p. 363, 1897) has determined for a great number of substances the position of the absorption bands, and Dr. Müller (Erlangen Inaugural Dissertation, 1903, *Sitzungsberichte der physikalisch-medicinischen Societat in Erlangen*, vol. xxxiv., p. 188, 1902) has tried to get some values of the absorption coefficients of vapours. By the researches of Friedrichs and Grebe, the results of Pauer have been in many respects amplified. Perhaps I may direct attention to the fact that Dr. Pauer found that the law of Kundt on the displacement of the absorption bands towards the red with increasing refraction index or dispersion is true when passing from the vapour to the liquid and then to the solutions in different media. His observations were made on benzol, toluol, the isomers of xylol and æthylbenzol, chlorobenzol, bromobenzol, iodobenzol, anilin, nitrobenzol, pyridine, bisulphide of carbon. Benzol and bisulphide of carbon were especially carefully treated by him.

Erlangen, November 13 E. WIEDEMANN.

The Second Law of Thermodynamics.

Is it not true that the Second Law of Thermodynamics is contradicted by the known facts of diffusion? When, for instance, masses of hydrogen and nitrogen are separated by a palladium partition, a difference of pressure is set up, owing to the diffusion of some of the hydrogen into the compartment which at first contained only nitrogen. In this condition the system is able to do work at the expense of its own heat, or heat entering from without. The palladium, in fact, takes the place of Clerk Maxwell's Sorting Demon, though, in this case, the process cannot be made continuous. M. A. BROWNE.

Christ's College, Cambridge, November 10.

BRITISH EXCAVATIONS IN THE NEAR EAST, 1904–5.

DURING the past year British archæologists have carried on the work of disinterring the remains of the ancient civilisations of Greece, Egypt, and Mesopotamia with energy. The excavations of the Trustees of the British Museum at Ephesus have resulted in interesting discoveries. The work was intended to supplement and complete that carried out under the auspices of the Trustees from forty to thirty years ago on the site of the Great Temple of Diana of the Ephesians. That work, carried out by the late Mr. J. T. Wood, resulted in the planning of the temple and the removal to England of many valuable antiquities now in the British Museum. The present work was entrusted by the trustees to the distinguished archæologist Mr. D. G. Hogarth. It has resulted in the discovery, undreamt of by Wood, of the remains of two earlier temples below that of the Crœsus temple, which he supposed to be the earliest, and of a vast number of votive objects of the eighth and seventh centuries B.C., among them many of gold and silver, besides Egyptian blue composition scarabs of the early twenty-sixth dynasty period. These were found underneath the second or "præ-Crœsus" temple. By the laws of Turkey, the antiquities, especially those of precious metal, must go to the Museum of Constantinople, but duplicates will come to the British Museum. Much new knowledge of the third or Crœsus temple, discovered by Wood, has also been gained. The two earlier ones seem to have been of interesting construction. Much heavy pumping work had to be carried out in the temple area, which had become filled with water. Mr. Hogarth is to be congratulated on having brought this interesting work to a successful conclusion.

On the mainland of Greece, Lakonia has been handed over by the Greek Government to the British School of Athens for excavations. Several minor discoveries of interest have been made, including that of a fifth-century local *heroön*, or hero-shrine, with its equipment of cultus-images, reliefs, figurines, and votive cups, &c., near Monemvasia. The work was carried out by Mr. R. C. Bosanquet, the Director of the School, and Mr. F. C. Hasluck.

The Cretan work of the British School has now been brought to a conclusion. The excavation of the site of Palaíkastro, in the province of Sitía, has not yet been completed, but is suspended, let us hope not for long. Mr. R. McG. Dawkins was in charge, and carried out his work most successfully under adverse conditions, owing to the now unhappily renewed troubles in the island, due to the fixed determination (whether it be right or wrong) of the Cretan people to effect their union with Greece. We can, parenthetically, only pray that Candia may not be the scene of riots, not for the sake of the Cretans, but for that of the museum, which contains all the trophies of the last few years' wonderful discoveries at Knossos and Phaistos, the destruction of which would be an irreparable loss to the whole civilised world.

This by the way. Mr. Dawkins's work has resulted in the discovery of the complete stratification of the temple site back to the first post-Neolithic age, and the discovery of fine pottery of the various stages of the Minoan period. It is evident that the later temple was built over the Minoan settlement, probably as the result of a survival of religious tradition in connection with the site. The exploration of the Minoan town has been regularly continued. In the hills near by Mr. Dawkins also discovered a Neolithic settlement with a very interesting deposit of twenty stone axes, "more than half of them in brand-new condition. This discovery gives us, for the first time in the Ægean, a definite idea of a Neolithic homestead."

The explorations of Messrs. Arthur Evans and Mackenzie at Knossos have been continued with the assistance of Mr. Doll as architect. By the kindness of Dr. Evans we are enabled to give a short sketch of the results of his work this season in advance. The chief work has been the exploration of the magazines on the paved way leading west from the "Stepped Theatral Area" (see NATURE, October 5). More stores of tablets relating to the royal chariots and armoury have been found, and a complete building excavated. On the hillside beyond the Candia road, the building to which the way led from the palace has been found and partly excavated. It proved to be a late Minoan house, larger than any other *dépendance* of the palace, and in it were found the remains of a shrine containing fetish images in the shape of natural stalagmite blocks of quasi-human form, together with a painted clay goat and other figures. Owing to heavy rainfall, the modern wooden pillars of the quadruple staircase in the main palace gave way, and Dr. Evans was obliged to rebuild the whole. This he did in more solid form with stone pillars of ancient shape and appearance. More interesting discoveries were made during the course of the work. We regret to learn that owing to absence of outside support for the Cretan Exploration Fund the Knossian excavations may shortly be brought to an end. It is evident that an excavator cannot go on bearing indefinitely the greater part of the cost of his excavations himself, as Dr. Evans has done. There is much more of the greatest importance to science to be found at Knossos, and we again appeal to those who are interested to subscribe to the Cretan Exploration Fund. There ought to be some money somewhere for the most important archæological exploration of the decade, which, despite the claims of Egyptian excavations, Dr. Evans's work must undoubtedly be admitted to be. We hope and confidently expect that, after a pause of a year or two devoted to the full publication of the momentous results hitherto obtained, Dr. Evans will be enabled to proceed afresh with the exploration of Knossos.

In Egypt the chief excavations of the year have been those of the Egypt Exploration Fund. The excavators employed by the fund were, as before, Profs. Naville and Petrie, and Messrs. Hall, Currelly, and Ayrton, Mr. Hall being lent, as last year, by the British Museum. To Messrs. Naville, Hall, and Ayrton was assigned the continuance of the excavations at Dêr el-Bahari, with the assistance of Mr. and Mrs. H. Garnett-Orme, who kindly gave their services to the Fund for this work. Messrs. Petrie and Currelly, with a party of helpers, among whom may be mentioned Captain Weill, of the French *génie*, were commissioned to investigate and clear

the well known temple of Sarábit el-Khadim, in the Sinaitic peninsula. Captain Weill has made the Egyptian inscriptions of Mount Sinai his special study.

The results of the first season's work on the eleventh dynasty temple at Dêr el-Bahari were described in NATURE, June 16, 1904; those of the second season have been equally interesting and important. The new temple is, in fact, the oldest now known at Thebes, and is the best preserved of the older temples of Egypt. It is the only temple of its period (about 2500 B.C.) known to us, and is therefore important as telling us previously unknown facts with regard to the architecture and art of that time. The temple is the funerary chapel of King Neb-hapet-Rā (formerly called "Neb-kheru-Rā") Mentuhetep, the first great Theban king. Last year's excavations were brought to an end when only a corner of the temple had been uncovered. Those of this year have resulted in the clearance of the main portion of it, leaving only the western end to be excavated this winter. It is a symmetrical rectangular building built upon an artificially levelled platform of rock. In the centre is a square erection which was apparently the base of a dummy pyramid of small size. Round this is an ambulatory or corridor of octagonal pillars, the outer wall of which was decorated with coloured reliefs. The platform was approached from the east on its centre line by an inclined plane or ramp, flanked by colonnades of square pillars on the lower level. This arrangement of platform, ramp, and flanking colonnades was apparently copied by the later architects of the temple of Queen Hatasu or Hatshepsut close by, which was excavated for the Egypt Exploration Fund by Prof. Naville, assisted by Mr. D. G. Hogarth and others, some years ago. The main arrangement of the old temple, with its central pyramid, &c., was not copied by Hatshepsut's architects.

A large number of fragments of the reliefs already mentioned have been found this year as last, and were exhibited at the annual exhibition of the Egypt Exploration Fund in the rooms of the Society of Biblical Archæology in July of this year. The brilliancy of their colouring and delicacy of their workmanship were remarkable, and they form an important addition to the chief known relics of Egyptian art. The carving of some of the sculptured hieroglyphs is of the finest style, which is not often seen in Europe, and was hardly known to many who had not visited Egypt and seen Abydos and Dêr el-Bahari.

Apart from the actual temple-buildings, the two most important discoveries were those of the sarcophagi of the priestesses of Hathor who were buried within the temple, and six portrait statues of the King Usertsen or Senusret III. of the twelfth dynasty, representing him at different periods of his life. The heads of two are missing. The portraits, especially the two oldest, are very fine. One of the white limestone sarcophagi is most beautifully carved with scenes of offerings being brought to the deceased priestess, of the cows of Hathor, &c. The sarcophagus and one of the statues are illustrated in an article on the temple by Mr. Hall in the August number of *Man*, from photographs taken by Mr. Ayrton.

The small votive offerings which were such a feature of last year's discoveries were not found in any quantity this year, but instead a much larger number of workmen's tools, hoes, baskets, mallets, &c., were found.

Prof. Petrie's work consisted in the clearance and planning of Sarábit el-Khadim and the study of the Wadi Maghara inscriptions. In the Wadi Maghara an inscription of the early King Sa-nekht, whose tomb was discovered by Mr. Garstang at Bêt Khallâf, in Upper Egypt, a few years ago, was found. The peculiarities of the plan of Sarábit el-Khadim had long been known, and now that they have been fully made out they appear sufficiently curious to demand some explanation, which Prof. Petrie has attempted to give. He explains the building as not primarily an Egyptian but a Semitic shrine, with *ḥanefiya* courts like those of a mosque, while the peculiar stelæ inscribed with records of Egyptian miners and the upright stones, which are such a feature of the place, he identifies as Semitic *bethels* or *baetyli*. Prof. Petrie also claimed this as the only Semitic temple known. His conclusions do not, however, seem to be altogether approved by other archæologists, and Mr. R. C. Thompson, of the British Museum, has criticised them in a recent article in *Man*, to which Prof. Petrie has replied, with the result of drawing a further reply from Mr. Thompson. The point about this being the only Semitic temple must undoubtedly be abandoned; the Babylonian temples are far older. That they are Sumerian is no argument against this, for the Semites took over most of their religious ideas from the Sumerians; but to an unprejudiced critic the weakest point of Prof. Petrie's argument seems to be the identification of the stelæ as *bethels*. If they were, they would, as Mr. Thompson says, be inscribed, not with mere records of Egyptian garrison and mining officials, with prayers to the Egyptian goddess Hathor, as they are, but with inscriptions of *Semitic* religious import, recording dreams and prophecies, &c. Prof. Robertson Smith's "Religion of the Semites" should be consulted on this point. The form of the stelæ is as Egyptian and non-Semitic as their inscriptions; we may compare with them the stela or obelisk of Usertsen I. at Begig, in the Fayyûm, and the two great stelæ in front of the funerary temple of King Sneferu at Mêdûm, discovered by Prof. Petrie himself in 1891.

A large number of interesting objects were brought back by the expedition, and were exhibited by the Egypt Exploration Fund at University College, Gower Street, in July.

Excavations have been carried on by Mr. Garstang for the University of Liverpool at Kom el-Ahmar, the site of the ancient Hierakonpolis, at Hissaya, south of Edfu, and at Esna. At Kom el-Ahmar Mr. Garstang found interesting remains of the third dynasty or earlier, at Hissaya graves of the Persian period, and at Esna a series of town-remains from Hyksos times until the twentieth dynasty. Two remarkable tomb-structures were found, of eight or ten chambers on the ground floor and a stairway leading up to the first floor, where there was a similar series. The site in general illustrated in an interesting fashion the provincial art of Egypt at the period. Excavation is to be resumed on it next year. We are indebted for these details to the kindness of Mr. Garstang.

In Mesopotamia the excavations of the British Museum at Kuyunjik, the site of Nineveh, have been brought to an end under the direction of Mr. R. C. Thompson, after the departure of Mr. L. W. King. The excavations have resulted in the discovery of many interesting buildings previously unknown, including a temple of the god Nabu and a new palace of Sennacherib. The planning of the whole mound of Kuyunjik and its ruins has been carried out to its completion. Messrs. King and Thompson also visited the rock of Behistun or Bisutun in Persia, and re-copied the famous historical inscription of Darius, originally copied by Rawlinson. The text obtained by them will be the

most complete and authoritative existing. Messrs. King and Thompson have also taken some unique photographs of the monument.

In the Sudan, Dr. Budge, of the British Museum, and Mr. J. W. Crowfoot, Inspector of Education in the Sudan, have completed the work which the former began at Meroe in 1903. They finally cleared out the shrine of the largest pyramid, and made some interesting explorations in the country near the Second Cataract. Dr. Budge, whose services had been previously lent to the Sudan Government by the British Museum in 1897, 1899, and 1903, is now engaged on an account of his four missions to that country, which is announced to appear in the spring.

We cannot close this account of British archæological work without a word of congratulation to our American friends on the success of the excavations of Mr. Theodore N. Davis, assisted by Mr. J. E. Quibell, the British Inspector of Antiquities in Upper Egypt, in the Valley of the Tombs of the Kings at Thebes. Mr. Davis found the untouched tomb of Iuaa and Tuaa, the father and mother of the great Queen Tyi, consort of Amenhetep III. and mother of the heretic King Akhunaten. The tomb was full of the most magnificent furniture, chariots, &c., mostly thickly overlaid with gold. Mr. Davis will proceed with his excavations this winter with the assistance of Mr. Ayrton, who has left the Egypt Exploration Fund for this purpose.

THE BEAUTY OF MINUTE STRUCTURE IN NATURE.[1]

ONE of the many ways of beginning the study of natural science is with a "beauty-feast"—of flowers or birds, of shells or gems, of anything—for all natural things are beautiful, in their proper setting at least. It is an old-fashioned mode of approach, commending itself to children and simple minds, but one which often leads far beyond æsthetic pleasure to the joy of understanding. It affords a dynamic to investigation, and fosters a healthy reverence for things. In school "nature-study" the æsthetic factor should be characteristic, though it is too often conspicuous by its absence. Indeed, if we had to choose, we should prefer admiration without science to science without admiration. But a simple book like that before us shows that there is no necessary antithesis; it is a disclosure of beautiful things, and yet within its limits it is quite scientific.

The author's aim is to illustrate by well chosen examples the beauty of minute structure, the beauty which the microscope discloses, and he is to be congratulated on his success. While older books on "the wonders of the microscope" had to be content with drawings, some of which were exquisitely done, this book presents us with photomicrographs of the highest excellence. It is difficult to over-praise them. Moreover, while the older books gave too much prominence to curiosities and out-of-the-way objects, we are here brought into close quarters with the familiar, with diatoms and Foraminifera, the whelk's radula and the barnacle's cirri, the butterfly's "tongue" and the scales of the sole, the spine of the sea-urchin and the spider's foot, a gnat and a house-fly's eggs, the dodder entering the clover, the bud of the lily flower, the sting of the nettle and the stem of wheat, and so on through a long list. Along with each of the sixty-five illustrations there is a short and clear description, and a note of the conditions of the photograph, *e.g.* magnification, focal distance, and exposure. The photographs were taken by Mr. Arthur E. Smith, and are certainly among the finest that have ever been published. They were taken, for

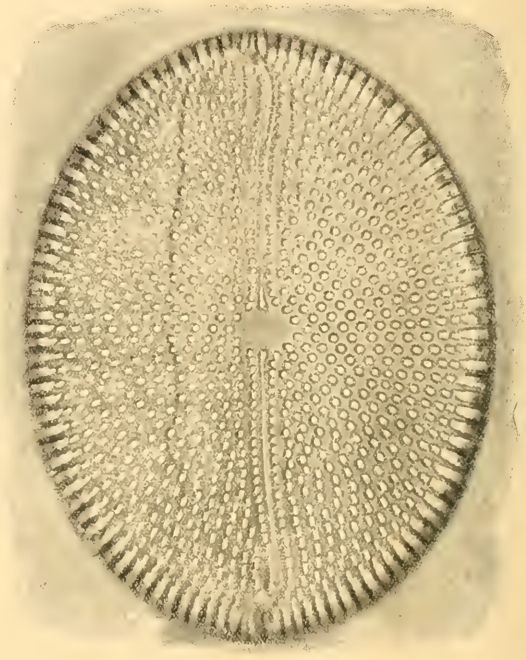

FIG. 1.—Diatom, from Bori, Hungary, × 1000. From "Nature through Microscope and Camera."

the most part, on 12 by 10 plates, and have been somewhat reduced in the process blocks. Mr. Smith contributes a useful chapter of practical hints on photomicrography.

Mr. Kerr is an enthusiastic photographer, who believes in his "intellectual pastime" as helping, indirectly, to remedy some of the ills we are heir to, such as "the amusement fetich." But he is more, he is a student of the beautiful things which he delights in, and he can tell their story in a plain, straightforward way. The moral that adorns his tale is expounded by Prof. G. Sims Woodhead in a finely conceived introduction; but we shall only say this, that the whole spirit of this beautiful book is well

[1] "Nature through Microscope and Camera." By Richard Kerr; with 65 photomicrographs by Arthur E. Smith. Pp. 197. (London: Religious Tract Society, 1905.) Price 6s net.

expressed in the prefatory quotation from Sir J. F. W. Herschel:—"To the Natural Philosopher there is no natural object that is unimportant or trifling; from the least of Nature's works he may learn the greatest lessons." J. A. T.

THE WASTAGE IN ARMIES BY DISEASE.

THE recent utterances of Sir Frederick Treves on the subject of the Army Medical Service (see NATURE, November 2, p. 15), and the discussion on enteric fever in the army which has appeared in the columns of the *Times*, have again directed attention to the inadequacy of the means taken in our army to prevent the incidence of enteric fever and other filth diseases. The crux of the matter is this: we have to provide hospital accommodation for 10 per cent. of our forces in the field, the Japanese for but 2 per cent. Why this difference? In the South African campaign no less than 746 per 1000 of the fighting forces were admitted into hospital for disease which is mainly preventable. In this war there were something like 450,000 admissions to hospital on account of sickness and some 22,000 admissions on account of wounds or injuries received in action.

"Among those admitted to hospital on account of disease alone, there were 14,800 deaths during the whole war; further, so far as can be estimated at present, 42,741 of the total admissions to hospital on account of disease, and 7998 of the deaths from disease, were due to enteric fever, while 31,363 of the admissions and 1248 of the deaths were from dysentery. In other words, no less than one-tenth of the admissions on account of disease were for enteric fever, and one-fourteenth were for dystentery, or these two diseases alone were the cause of practically one-sixth of the total admissions and about two-thirds of the total deaths on account of disease; these two diseases also accounted for nearly one-half of the total losses by death from all causes during the war. As we know that both enteric and dysentery belong to the group of diseases which are largely the outcome of faulty environment, the sanitary significance of these figures needs no argument."[1]

How does the Japanese Army deal with the prevention of disease? The following record sufficiently answers this question:—

"The care of the sick and wounded occupied but a small share of the time of the medical officers. The solution of the greater problem of preventing disease by the careful supervision of the smallest details of subsistence, clothing and shelter was their first and most important duty. Nothing was too small to escape their vigilance, nor too tedious to weary their patience, and everywhere, in the field with the scouts or in the base hospitals at home, the one prevailing idea was the prevention of disease. The medical officer was to be found both in the front and in the rear. He was with the first screen of scouts, with his microscopes and chemicals, testing and labelling wells, so that the army which followed should drink no contaminated water. When scouts reached a town, he immediately made a thorough examination of the sanitary conditions, and if cases of contagious or infectious disease were found, he put a cordon around the quarter where they were. A medical officer accompanied foraging parties, and, with the commissariat officers, sampled the various food, fruit, and vegetables sold by the natives before the arrival of the army. If the food were tainted, or the fruit over-ripe, or if the water required boiling, notices to that effect were posted in suitable places. So strict was the discipline from commanding officer to rank and file that obedience to the orders of the medical officer was absolute. The medical officer also supervised the personal hygiene of the camp. He taught the men how to cook, how to bathe, how to cleanse the finger nails so as to free them from bacteria, as well as how to live in general a healthy, vigorous life, and it was a part of the soldier's routine to carry out these instructions in every particular. As a result of this system the medical officer was not obliged to treat cases of dysentery and fevers that follow the use of improper food and the neglect of sanitation. During six months of terrible fighting and exposure in a foreign country there was only a fraction of 1 per cent. of loss from preventable disease."[1]

It may be true that vehicles other than water, particularly dust and flies, convey the infection in enteric fever, diarrhœa, and dysentery, but much can be done by safeguarding the water supplies.

Diminish the incidence of these diseases by any means whatever and the subsequent incidence of the disease will naturally be lessened—cases beget cases.

It may or may not be practicable to sterilise the drinking water for a big army in the field, but in camps and in small campaigns such as our "little wars" on the Indian frontier, and in Africa, a great deal more could be done than has been done. Thus in the Tochi Valley, in 1897, a force of some 4000 men was condemned to inactivity and suffered severely from diarrhœa, dysentery, and enteric. The British troops averaged an *annual* strength of 622, and among them there were 59 cases of enteric with 30 deaths, 371 cases of dysentery with 65 deaths, and 211 cases of diarrhœa with 10 deaths. Here was an ideal instance in which sterilisation of the water or distillation for the sick (as the water was very saline) could have been carried out, as there was plenty of fuel, and the extra cost involved would probably have been more than covered by the saving in pensions, &c. Lieut. Nesfield, I.M.S., in the Tibet campaign used his iodide iodate tablets (see NATURE, July 27, p. 303, and August 31, p. 432), with the result that of 700 men who drank water sterilised with them, none contracted cholera, while of other batches of men passing through the same region a few days later an average of 3 per cent. contracted cholera.

There can be no question that the medical officers of our army are a devoted body of men, highly trained, and fully alive to what should be done, but they are too few adequately to cope with the problem of prevention, and what is more they receive little encouragement in this direction from those in authority. In addition, a body of intelligent trained non-commissioned officers and men, a sanitary corps, is required to carry out the policy of the medical officers. At present guards for the water supply and similar purposes are drawn from the ordinary strength of the regiments, with, of course, no special training. In the China Relief Expedition in 1900 the Japanese provided three skilled men to take care of their sick and wounded for every two provided by the other armies. In olden times it was thought cheaper to obtain a new soldier than to cure a sick or wounded one; the reverse is the case nowadays if the authorities would but appreciate it, and prevention is even better than cure. R. T. HEWLETT.

NOTES.

WE announce with deep regret that Sir J. S. Burdon Sanderson, Bart., F.R.S., late Regius professor of medicine in the University of Oxford, died at Oxford on November 23.

PROF. EMIL WARBURG, president of the Reichsanstalt in Charlottenburg, and Prof. Henri Moissan, of the University of Paris, have been elected corresponding members of the Academy of Sciences of München.

THE twenty-first anniversary of the Royal Scottish Geographical Society was celebrated by a dinner in Edinburgh on Monday, November 27. Prof. J. Geikie, the president of the society, presided.

[1] Lieut.-Col Firth, R.A.M.C., *Journ. of Hygiene*, Sept., 1905, p. 543.

[1] *Brit. Med. Journ.*, 1904, ii. p. 1332.

THE death is announced of Dr. James Monckman on November 18, at the age of sixty-three. In 1879, after acting as honorary assistant to Prof. J. J. Thomson at Cambridge, Dr. Monckman received the degree of D.Sc. of London University. At Bradford he acted occasionally as consulting analytical chemist, and he carried out some researches in chemistry, as well as work in geology and botany. He assisted in the formation of the Bradford Scientific Society, and was thrice elected its president.

A DISTINCT earth tremor occurred in Manchester and Salford about 3.45 a.m. on November 25. Many people dwelling on the north-west side of the city and borough reported that they were disturbed from sleep by violent shaking of their rooms and the ringing of bells. Some persons reported that they heard a loud thud; others that there was nothing but one violent shock, followed by a tremor lasting several minutes. In the Seedley district of Salford some chimney stacks were displaced, but there was no other damage.

DR. F. AMEGHINO seems to be impressed with the idea that Argentina is the "centre of the universe," and that almost every group of mammals may be traced back to a South American ancestor. In the third of three papers dealing with the presence of a perforation in the astragalus of several groups of mammals, published in vol. xiii. of the *Anales* of the National Museum of Buenos Aires, he gives, for instance, a phylogeny in which both pangolins (Manidæ) and aard-varks (Orycteropodidæ) are placed as being derived from armadillos (Dasypodidæ). A more unsound pedigree it would be almost impossible to invent. Dr. Ameghino has detected the above-mentioned foramen not only in Orycteropus, but also in Canis, Typotherium, and certain mammals from the Middle Miocene of France.

AMONG the contents of the November issue of the *Naturalist* is a communication by Mr. A. Whitaker on the breeding habits of British bats. Unfortunately, the author's attempts to rear bats in captivity have been only partially successful, in some degree owing to the circumstance that it was not ascertained until too late that a female specimen was pregnant. One noctule bat gave birth, however, to an offspring almost immediately following its capture, and it was noticed that the squeak of the "baby" was even more high-pitched than that of its mother. When the young one was eleven days old (and still blind and naked) the parent escaped, but apparently returned and carried away her offspring. Neolithic remains from the Durham caves form the subject of a paper by Mr. C. T. Trechmann in the same issue.

ACCORDING to *Museum News*, No. 4, the Brooklyn Museum, which is in the van of progress, has been trying the experiment of placing, for the use of visitors, books relating to the subject of the specimens exhibited on tables alongside the various cases. So far the experiment seems to have been a decided success, but whether it could be repeated in this country may be doubtful. Apropos of descriptive labels in museums, it is stated in the same periodical that if ninety-nine objects are labelled and the hundredth is not so treated, visitors will pass over all the former and inquire for the label for the latter. Again, a visitor has been known to look at a label some six feet long, inscribed in letters three inches high "Atlantic Right Whale," and then turn round and ask the nearest official "what that animal is called"!

No. 25 of the "North American Fauna," issued by the U.S. Department of Agriculture, consists of an account of the biological survey of Texas which has been recently carried out. This part, which is by Mr. V. Bailey, deals, however, only with the determination of life-zones, and the reptiles and mammals, the birds being reserved for a future issue. The economical aspect of the subject has claimed a large share of the attention of the workers, especially as regards the suitability or otherwise of particular crops to particular climatic zones. The mapping of these zones—which are necessarily also life-zones—cannot fail to be of advantage to agriculturists, for "as a crop becomes an established success in one locality, a study of the zone-map will show over what adjoining county it can be profitably extended." Of the nine new mammals described, all but one are subspecies, thus showing how thoroughly the country has been worked.

DR. FORSYTH MAJOR has favoured us with a copy of an interesting and important paper from the October and November numbers of the *Geological Magazine* on certain rodents from the Pleistocene of the western Mediterranean countries. He first of all deals with the picas, or "mouse-hares," of the extinct genus Prolagus, which, instead of being confined to Sardinia and Corsica, is also continental, and extends as far west as Spain. Next it is shown that Hensel's *Mus orthodon*, which has been supposed, apparently owing to a misconception, to be akin to *M. sylvaticus*, represents a genus—Rhagamys—by itself. It has, for instance, tall-crowned molars with very thick enamel, and nearly vertical tubercles, which when worn present a characteristic pattern. Finally, the Pleistocene *Arvicola henseli* is shown to form a kind of connecting link between the Pliocene Mimomys, in which the molars are rooted, and modern voles, the dentine surfaces of the prisms of the latter being incompletely separated.

RECENT miscellaneous results of the work of the U.S. Bureau of Entomology are summarised in Bulletin No. 54 of that section of the Agricultural Department. One article is devoted to the sugar-cane beetle (*Ligyrus rugiceps*), on which a special investigation was undertaken last year, owing to the fact that the insect, and the best means of checking its ravages, had received practically no attention for the last five-and-twenty years. It is hoped that the remedies suggested will be found efficient by southern planters. "Conchuella," a Mexican cotton-pest, which it is feared may spread to Texas, has also received attention at the hands of the bureau's officers, while the demonstration of the efficiency of cold storage for "cow peas" (so largely used as fodder and for the improvement of the soil in the States) as a protection against the attacks of the three species of weevils to which they are subject may be regarded as a triumph for the bureau.

WE have received from the trustees a copy of "A Guide to the Fossil Reptiles, Amphibians, and Fishes in the Department of Geology and Palæontology in the British Museum (Natural History), Cromwell Road," issued at the price of sixpence. Although on the title-page merely stated to be the "eighth edition," this excellent little handbook has been entirely re-written by Dr. A. Smith Woodward, the keeper of the department, whose name is a sufficient guarantee that it is thoroughly up to date, and at the same time lucidly and simply written. In its new form it constitutes a brief, popular introduction to the study of the extinct representatives of the groups to which it is devoted. The most striking illustration is one of Mr. Carnegie's dinosaur, Diplodocus, which from considerations of space has been mounted in the gallery mainly devoted to recent reptiles, instead of among its fellow monsters. The plate of the skulls of two of the wonderful extinct horned tortoises—one from Queensland and the other from Patagonia—likewise merits a word of commendation.

MR. WINSLOW AND MISS ROGERS have suggested a new classification of the bacterial family Coccaceæ (*Science*, xxi., No. 539, p. 669). The family is divided into two subfamilies, the Paracoccaceæ and Metacoccaceæ, the former being subdivided into two genera, Diplococcus and Streptococcus, the latter into three genera, Micrococcus, Sarcina, and Ascococcus. We are not sure that this revised classification is a material improvement on the classifications which already exist. For instance, the Pneumococcus is included among the Diplococci, but culturally it is unquestionably a short Streptococcus, and in the sputum may occur in chains of four elements.

ALTHOUGH yams, the tubers of species of Dioscorea, are extensively cultivated in the West Indies and the tropics of South America for domestic consumption, their value as a food does not appeal to the Ceylonese, who show a preference for the less tasty and less nutritious imported potato. In the Circulars (vol. iii., No. 1) of the Royal Botanic Gardens, Ceylon, Mr. H. F. Macmillan has written some notes on Dioscoreas with the object of directing attention to their value as a vegetable, and also to assist cultivators in identifying the different varieties.

THE members of the Scottish Antarctic Expedition were prevented by stress of weather from making a complete exploration of Gough Island, so that the collection of plants obtained by Mr. R. W. Brown, and described in vol. xxxvii. of the *Journal of the Linnean Society*, is probably incomplete. Of the phanerogams and ferns, numbering twenty-seven, the most conspicuous were *Phylica nitida*, a tree characteristic of the Tristan da Cunha group, tussac-grass, *Spartina arundinacea*, and the tree fern *Lomaria Boryana*. The flora is very similar to that of Tristan da Cunha, but two endemic species, a Cotula and an Asplenium, were obtained.

AT the recent Colonial Exhibition held in the Crystal Palace, of the West Indian colonies Jamaica took the foremost place, receiving, amongst other distinctions, the gold medal presented by the West Indian Cable Company for the best collective exhibit. Of Jamaica produce, oranges and bananas are both much in evidence; the sugar and rum industries are prospering, while the cultivation of cacao, rubber, cotton, and tobacco are all more or less suited to the climate. In the *Agricultural News* (October 7) mention is also made of a tea plantation of 90 acres that promises well under the careful management of the owner, Mr. H. E. Cox. This and a plantation in Carolina, U.S.A., are said to be the only tea plantations in the western hemisphere.

MR. D. E. HUTCHINS, conservator of forests, Cape Town, presents an admirable survey of the past history and present condition of forestry in South Africa in the recent record of "Science in South Africa." The institution of a forest department in Cape Colony dates from 1881; since that time three-quarters of a million pounds has been expended, and the staff now numbers no less than 110 conservators and foresters. Yellow-wood furnished by two species of Podocarpus, the most widely spread indigenous timber trees, is not so valuable as the Clanwilliam cedar, *Callitris arborea*, which takes the place of Baltic pine; this cedar having been cut out in the past, future supply is dependent upon the timber that is now being raised in the Cedarberg country. Of exotic trees, species of Eucalyptus and Cupressus have been largely introduced for timber, and wattles for the production of tan bark.

NEARLY all parts of the British Islands experienced very severe southerly and south-westerly gales on Sunday last, November 26, which, in connection with the spring tides, occasioned great damage, especially on the west and south coasts, many houses being flooded, while the service in the English Channel was quite disorganised. The weather report issued by the Meteorological Office on Saturday morning notified the approach of an important depression off the coast of Ireland, and the chart for Sunday morning showed that the centre of the storm had already reached the west coast of that country, and that the barometer had fallen 0·7 inch in the last twenty-four hours. In the north-west of England the strongest winds were felt between 10h. p.m. and midnight, and the gusts reached a velocity of 66 miles per hour; in the south-west of England the velocity was at least 75 miles an hour. At the mouth of the Thames it is estimated that the gusts were at the rate of about 60 miles an hour. Notwithstanding the great damage caused by wind and sea combined, it does not appear that the wind-velocity was so great as in the storm of March last, when a rate of 100 miles an hour was recorded in the south-west of England, and 83 miles an hour in the north-west. By Monday morning the central part of the storm had advanced to the coast of Norway.

IN the Journal of the Meteorological Society of Japan for September will be found a very useful summary (in English) of the rainfall of China and Corea, by Mr. T. Okada. Some years ago Dr. Supan published a valuable paper on the subject in Petermann's *Mitteilungen*, but since that time the number of stations has increased, and Mr. Okada has summarised in a handy form the results for forty stations, mostly on the coasts of China and Corea, for the years 1892–1901. The materials are obtained from observations published by the Zi-ka-wei and Hong Kong observatories, and other sources. In northern China the average annual rainfall is under 40 inches; it increases to the southward, and decreases from the coast towards the interior of the Empire, and in individual years it is subject to large fluctuations. In Corea the annual fall is about 36 inches on the west coast, and is generally more than 40 inches on the east and south coasts. In northern China the wettest months are July and August, and February is the driest month. In southern China the wettest month is June, and the driest December. Tables are given showing the average monthly falls at all stations. The coast of central China has an average of 120 rainy days, southern China 80 days, and northern China 60 days. Heavy rainfall in twenty-four hours is rather rare, but falls of 4 inches frequently occur between April and August. In Corea falls of more than 4 inches in a day rarely occur. There is only one instance of more than 8 inches. A table is given showing the greatest daily falls in each month for all stations.

A REPORT has been received on the use of platinum resistance thermometers in determining the temperature of the air at Helwan, the central Egyptian observatory. The object of the paper is to justify the use of a special form of platinum thermometer invented by the writer of the report (Mr. E. B. H. Wade), in conjunction with Prof. Callendar's electric recorder. Instead of coiling the platinum wires on mica supports, and enclosing them in a solid tube for protection, as in the ordinary recorder, Mr. Wade arranged them in an open manner on a light ebonite frame, somewhat in the form of a gridiron, without any kind of casing, the wire being completely exposed to the air. It is claimed, among other things, that the influences of radiation and the Joule effect are much

smaller in this type than in the ordinary one, that it acts more rapidly in its indications, and that the combined recorder and open thermometer may be standardised in such a way as to require no control readings. The author gives a number of tables which seem to show that the advantages claimed are supported by the results obtained. Specimens of thermograms obtained by the employment of the usual and of the modified type show that the fluctuations are more minute in the latter case. It is also stated that Prof. Callendar has expressed approval of the reasons which have led to the adoption of the modified type of thermometer.

THE *Rendiconti* of the Royal Lombardy Institution, xxxviii., 16, contains a short abstract of the report for 1904 of the meteorological observatory on Monte Rosa, by Dr. Camillo Alessandri. The "Capanna Regina Margherita," of which the first wing was opened in 1893, has from that time onwards been visited by many observers, chiefly in connection with physiological researches, and Prof. Mosso's work in this direction is well known; but it was not until May, 1904, that the Italian Meteorological Office placed Dr. Alessandri in official charge of a meteorological station there. During the short time available up to the date of the report, observations were made of temperature, atmospheric electricity, refraction, and time. The climatic conditions occasion great difficulties with the use of instruments, and the author proves the necessity of devising new forms of instruments specially adapted to these conditions. As a beginning, a new metallic thermometer and a registering electrometer have been described by Dr. Alessandri himself.

THE twentieth Bulletin issued by the Geological Survey of Western Australia (Perth) covers 127 pages, and forms a further report by Mr. A. Gibb Maitland on the geological features and mineral resources of the Pilbara goldfield. It includes full details regarding the Nullagine, Warrawoona, and Marble Bar fields, and is accompanied by coloured geological and mining maps. Special interest attaches to the Nullagine district on account of the occurrence of gold in sedimentary rocks bearing a close resemblance to the auriferous conglomerates of the Witwatersrand. The auriferous deposits of Warrawoona and of Marble Hill are quartz reefs.

AN interesting preliminary report has been issued by the mines branch of the Canadian Department of the Interior on the raw materials, manufacture, and uses of hydraulic cements in Manitoba. It has been drawn up by Mr. J. Walter Wells, and involved an examination of the limestones, marls, clays, shales, and coal deposits of the province. Particulars are added of the cement mills in North Dakota, in Minnesota, and in South Dakota; and much information is given regarding the manufacture of cement from the raw materials available that cannot fail to be of practical value in furthering the cement industry of Manitoba. In that province timber is becoming scarce, and suitable building stone and bricks are expensive. Cement is therefore coming into increasing use in house and farm construction, in railway work, in municipal work, and in factories and mills; and within the last eight years the uses of concrete have been greatly extended by the introduction of iron and steel reinforcements, consisting of skeleton structures so arranged in the concrete masses that rods, bars, wires, and bands help in resisting stresses in tension. A very important application of reinforced cement concrete in Manitoba is the construction of grain elevators. The various applications of cement in the province are well shown in photographic illustrations accompanying the report.

AT the last meeting of the Institution of Mechanical Engineers a paper was read by Dr. H. C. H. Carpenter, Mr. R. A. Hadfield, and Mr. Percy Longmuir on the properties of a series of iron-nickel-manganese-carbon alloys. It constituted the seventh report to the Alloys Research Committee, and formed an interesting continuation of the previous reports presented by the late Sir William Roberts-Austen. The research was carried out at the National Physical Laboratory, the alloys having been prepared by Mr. Hadfield at his works at Sheffield. The alloys contained on an average 0·44 per cent. of carbon and 0·88 per cent. of manganese, and the following percentages of nickel:—A, nil; B, 1·20; C, 2·15; D, 4·25; E, 4·95; F, 6·42; G, 7·95; H, 12·22; J, 15·98; and K, 19·91. The report embodies the results of an exhaustive examination of the mechanical, physical, chemical, and metallographical properties of these alloys. It has previously been shown that an increase in the content of nickel raises the maximum stress and lowers the extension. The present research shows that, so far as industrial products are concerned, a danger limit for nickel content is found at $4\frac{1}{2}$ per cent. when carbon and manganese are present to the extent of 0·44 per cent. and 0·88 per cent. respectively. The brittle zone extends from about 5 per cent. to 16 per cent. of nickel. The report, which covers 102 pages, contains a mass of observations of the greatest scientific interest, and the Institution of Mechanical Engineers is to be congratulated on having promoted a costly research of which the immediate practical value to the engineer is very slight.

WE have received from Mr. A. Gibb Maitland a copy of an interesting paper read by him before the Western Australian Natural History Society on the salient geological features of British New Guinea. The territory was annexed to the Crown in 1888, and in 1901 passed into the possession of the Commonwealth of Australia. The geology presents many points of interest. New Guinea rests upon a submarine bank which has been termed the Melanesian Plateau and is separated from another by an abyss 2000 fathoms deep. The coral formations of British New Guinea are very remarkable. All gradations from reefs only a few feet above the water up to 2000 feet in height were noticed. The reef masses are composed of very hard limestones. Coral fragments do not appear to be very common. The volcanic phenomena present all phases, their products being scattered over almost the whole length of the possession. The various sedimentary rocks are well developed in many portions of the territory, and, so far as at present understood, they comprise:—(1) Kevori grits (post-Tertiary); (2) Port Moresby beds (Pliocene); (3) Boioro limestones (undetermined age); (4) Purari River beds (Cretaceous); (5) Strickland River shales (Jurassic); (6) Tauri limestones (Devonian); and (7) metamorphic rocks and crystalline schists. The last named are of considerable economic importance in that they form the original matrix of those deposits that have yielded, from 1888 to 1904, alluvial gold to the value of 255,115*l*. Fragments of coal have been met with in the Purari River beds. It is believed that the formation must attain a thickness of 3000 feet, which would leave room for the intercalation of coal seams. Should a coalfield exist it might exercise a great influence on the future of the possession.

AN interesting paper on the linear force of growing crystals is contained in the *Proceedings of the Washington Academy of Sciences* (vol. vii. p. 283); the authors, Messrs.

G. F. Becker and A. L. Day, direct attention to the fact that in the study of ore deposits occurrences are observable in which crystals have exerted a very considerable force. Pyrites, for example, is formed in slate in such a way as to drive apart the laminæ of the rock without any perceptible deformation of the crystals occurring. A description is given of some experiments performed in order to determine the lifting force exerted by crystals of alum growing in a saturated solution whilst subjected to the pressure of a heavy weight. Under the title "An Interesting Pseudosolid," the same authors contribute an account of some investigations of the behaviour of fresh white of egg beaten into a fine foam with an equal volume of powdered sugar. Cylinders of uniform size were cut out of the mass of foam and subjected to compressive or tensile stress, the changes in the dimensions being carefully observed. A series of photographs of the entire foam cylinder after successive increments of compression was made, and then, by superposing the plates, accurate traces of the path of each component particle were obtained. The authors consider that the results obtained offer a confirmation of Prof. J. J. Thomson's theory of solids.

Mr. Wilhelm Engelmann, of Leipzig, has published a fourth, revised edition of Prof. P. Groth's "Physikalische Krystallographie und Einleitung in die krystallographische Kenntnis der wichtigsten Substanzen." The third edition of Prof. Groth's famous book was the subject of an article in our issue for January 30, 1896 (vol. liii. p. 289). Many students of crystallography will welcome the present edition.

A second edition of Dr. F. Mollwo Perkin's "Qualitative Chemical Analysis, Organic and Inorganic," has been published by Messrs. Longmans, Green and Co. The first edition was reviewed in our issue for August 22, 1901 (vol. lxiv. p. 397); and all that need now be said is that more theory has been introduced, the portions dealing with the analysis of acids and the treatment of the substance to be analysed have been recast, and several additions have been made, those in organic analysis being specially intended for university and pharmaceutical students.

A sixth edition, revised and enlarged, of Prof. R. Wiedersheim's "Vergleichende Anatomie der Wirbeltiere" has been published by Mr. Gustav Fischer, of Jena. An English edition, founded on the third German edition, was reviewed in Nature for September 1, 1898 (vol. lviii. p. 409). It is only necessary to state here that this standard work continues to grow in bulk; for instance, the bibliographical appendix, which in the English edition referred to runs to some ninety pages, occupies in the new edition nearly 140 pages.

Mr. Aksel G. S. Josephson, of the John Crerar Library, Chicago, has sent us a copy of a pamphlet in which he puts forward a proposition for the establishment of a bibliographical institute. Mr. Josephson maintains that as there are laboratories for chemical, physical, and hygienic research, there should also be an institute for conducting bibliographical research, where records of literary productions would be made systematically, and to which persons desiring information of a bibliographical character could turn with their inquiries. Such an institute, he remarks, organised as a bureau of scientific information, would be a boon to all investigators. The institute should be established on an international basis, and its function should be to record, classify, and evaluate printed literature. It should be part of the regular duty of the staff of the institute to index the society publications which are not included in existing indexes to periodical literature. Bibliographies of special subjects should be prepared to fill existing gaps. To establish such an institute on a reasonably permanent basis would, Mr. Josephson estimates, require an endowment of at least 200,000*l*.

OUR ASTRONOMICAL COLUMN.

Astronomical Occurrences in December:—

Dec.	2.	5h. Saturn in conjunction with Moon (Saturn 1° 21′ S.).
,,	3.	10h. 49m. Minimum of Algol (β Persei).
,,	6.	7h. 38m. Minimum of Algol (β Persei).
,,	8.	5h. 35m. to 6h. 43m. Moon occults μ Ceti (mag. 4·4).
,,	9.	4h. 49m. to 5h. 43m. Moon occults *f* Tauri (mag. 4·3).
,,	9.	5h. 48m. to 7h. 21m. Transit of Jupiter's Sat. III. (Ganymede).
,,	10.	4h. 58m. to 5h. 56m. Moon occults γ Tauri (mag. 3·9).
,,	10.	14h. 52m. to 15h. 53m. Moon occults α Tauri (mag. 1·1).
,,	10.	Saturn. Major axis outer ring $=38''\cdot34$. Minor axis $=7''\cdot31$.
,,	10–12.	Epoch of December meteors (Geminids, Radiant $108°+33°$).
,,	15.	Venus. Illuminated portion of disc $=0\cdot970$. Of Mars $=0\cdot900$.
,,	16.	9h. 5m. to 10h. 41m. Transit of Jupiter's Sat. III. (Ganymede).
,,	19.	19h. 53m. to 21h. 2m. Moon occults γ Virginis (mag. 3·0).
,,	22.	0h. Sun enters Virgo. Winter commences.
,,	23.	12h. 26m. to 14h. 6m. Transit of Jupiter's Sat. III. (Ganymede).
,,	25.	16h. Mars and Saturn in conjunction (Mars 0° 30′ N).
,,	26.	7h. Uranus in conjunction with the Sun.
,,	26.	9h. 21m. Minimum of Algol (β Persei).
,,	29.	6h. 10m. Minimum of Algol (β Persei).
,,	30.	20h. Neptune in opposition to the Sun.

Comet 1905*b*. The observation of comet 1905*b* at Bamberg on November 18 was made by Prof. Hartwig, who, in addition to determining the position given in these columns last week, recorded that the magnitude of the comet was 7·5, that the object was round with a diameter of 10′, and that the central nucleus had a magnitude of 11·0.

An observation made by Prof. Aitken at the Lick Observatory on November 18 gave the comet's position, at 8h. 17m. 31s. (Mount Hamilton M.T.), as

$$\text{R.A. (app.)}=0\text{h. }33\text{m. }54\cdot4\text{s., dec.}=+77°\ 17'\ 26''.$$

The appearance and the rapid apparent movement of this object seem to point to its comparative proximity to the earth (*Astronomische Nachrichten*, No. 4055).

The following elements and ephemeris, which have been computed by Herr M. Ebell from the observations of November 18, 19, and 20, are given in Circular No. 80 of the Kiel Centralstelle:—

Elements.

T = 1905 October 27·4926 (Berlin M.T.).

$$\left.\begin{aligned}\omega &= 135°\ 38'\cdot7\\ \Omega &= 223\ \ 45\cdot4\\ i &= 138\ \ 54\cdot6\end{aligned}\right\}1905\cdot0$$

$$\log q = 0\cdot02626$$

Ephemeris 12h. (Berlin M.T.)

1905	α (h. m. s.)	δ	log Δ	Brightness
Dec. 2	... 23 30 49	... +1 11·8	... 9·7150	.. 0·20
6	... 23 30 49	... −4 46·6	... 9·8163	... 0·12
10	... 23 31 28	... −8 36·1	... 9·9002	.. 0·08

Brightness at time of discovery = 1·0.

An observation made at Bamberg on November 21 gave corrections of −32s. in R.A. and +4′·1 in declination to the above ephemeris.

AN UNTRIED METHOD OF DETERMINING THE REFRACTION CONSTANT.—In No. 8, vol. xiii., of *Popular Astronomy*, Mr. Geo. A. Hill, of Washington, describes a new and, as he believes, an untried method for determining the constant of refraction.

Briefly, the method consists in observing the times at which two stars, separated by about twelve hours in right ascension, and both of nearly the same declination, transit across a horizontal wire *in the prime vertical*. In each case the refraction decreases the hour angle, and the arithmetical sum of the hour angles of the two stars will differ from the difference between their right ascensions by twice the refraction, expressed in time, at the zenith distance at which they were observed.

To make this observation Mr. Hill proposes the employment of an instrument similar in form and in the rigidity of its parts to the modern zenith telescope. The telescope is to be established in the prime vertical, and mounted so that it is capable of rotation about a rigid vertical axis. Two stops fixed to the base of the instrument would ensure that when the telescope was rotated in azimuth about the vertical axis its line of collimation would still be in the prime vertical. Obviously the ideal position for the making of the observations would be at or near to the earth's equator. Many other details of the proposed plan of observations are given at length in Mr. Hill's paper.

SPECTRA OF BRIGHT SOUTHERN STARS.—An appendix to vol xxviii. of the Annals—the volume in which appeared the "Catalogue of the Spectra of Bright Southern Stars"—has just been published by the Harvard College Observatory. It contains two tables, in the first of which there are given the particulars of sixty-nine stars which were accidentally omitted from Table I. in the original volume, and in the second the corrected classification of the spectra of thirty stars which were previously wrongly described.

A CATALOGUE OF 4280 STARS.—No. 15 of the *Publications of the Cincinnati Observatory* is devoted to a catalogue of the positions and precessional constants of 4280 of the stars given in Piazzi's catalogue.

All the stars given by Piazzi that were north of the equator in 1800, except those included in the Berlin "Jahrbuch" and eighteen of the Pleiades group, are included in the catalogue, and the Piazzi number, the position for 1900, the precession, the proper name, and the magnitude are given for each. An appendix contains the proper motions of 35 stars which were placed on the observing list, mostly taken from the Cambridge A.G. Catalogue.

HIGHER EDUCATION AT THE CAPE.

HIGHER education in Cape Colony is at the present time in a very interesting and perhaps critical condition. It is indeed characteristic of the tardiness of progress in that colony (the eternal motto is "Wacht een beetje") that the crisis should not have arrived until nearly eighty years after the foundation of the first institution designed to promote advanced studies—the South African College in Cape Town. The causes of this retardation are to be found partly in dissipation of effort, partly in the mischievous influence of an iron system of external examinations. The South African College was started on a small scale in 1829 through the liberality of a number of citizens of Cape Town, who became "shareholders" in the venture; but though after a few years it was recognised as a public institution and received support from the public treasury, it did not at first develop with much rapidity; and in 1849 Bishop Gray, after an unsuccessful attempt to buy out the majority of the "shareholders," founded the Diocesan College as a rival institution in the suburbs, thus inaugurating the unhappy policy of multiplying colleges from which the colony still suffers. Four years later Sir George Grey's administration instituted a public board of examiners with power to grant certificates in various subjects, another fateful step, for from that board there sprang in 1873 the University of the Cape of Good Hope, the only body in South Africa which has the right to confer degrees. The character of this so-called university deserves notice. It was modelled on the old University of London, the example of which it follows only too faithfully. It is managed by a council, half the members of which are appointed by Government, the other half elected by the convocation of graduates. It exercises the two functions of examining and granting degrees, but it does not teach. So abhorrent to it, indeed, is any connection with teaching that it does not allow teachers of candidates to take part in the examinations, a most deleterious prohibition, since in many subjects the only experts belong to the staffs of the colleges. Dissatisfaction with this examining university is the chief cause of the present crisis. Meantime the multiplication of colleges and the wasteful reiteration of similar work in a number of centres has gone on apace. Some of the smaller colleges have, it is true, died out; but there still remain, in addition to the two already mentioned, the Victoria College at Stellenbosch, which was incorporated in 1881, the Huguenot College for Women at Wellington (1898), and the Rhodes University College, which in 1904 took the place of St. Andrew's College at Grahamstown. The western province, therefore, has four colleges, all within forty miles of Cape Town, and the eastern province has one. They are bound hand and foot by the syllabuses and regulations of the university, for the examinations of which they prepare. Alike in strength and in character, however, they vary greatly. The South African College has in recent years developed with wonderful rapidity. It now supports seventeen chairs and has about 260 students, whom it draws in approximately equal numbers from the British and from the Dutch, and in thus bringing the two races together exercises a most beneficent influence, which it rightly regards as one of its chief claims to support. Its arts buildings are old and need reconstruction, but blocks of science buildings have lately been erected which would do credit to any unversity in the Empire, and the intention is to house the arts also on a similar scale. The only other college approaching it in strength is that of Stellenbosch, which has also developed recently, though it remains somewhat smaller and is less well equipped for the teaching of science. That the two strongest colleges should be in such close proximity is a particularly unfortunate result of the short-sighted policy (or lack of policy) which has been characteristic of the educational administration of the colony in the past. On purely educational grounds this duplication cannot be justified. But it is to be feared that racial rather than properly educational motives have led to the development of a second large college so near to Cape Town, and this may be said without any reflection upon the instruction given at it. For the Victoria College is almost completely under the influence of the neighbouring theological seminary of the Dutch Reformed Church; its students are almost entirely Dutch; it is in sentiment and in popular estimation the Dutch College. Even were the instruction provided the best in the world, it would be still altogether deplorable that this tendency to racial separatism in education should have gained recognition and support. Of the remaining colleges, that at Grahamstown has a fairly large staff, but as yet few students and no buildings, and in view of the backward state of education in the east its position seems a little precarious, but if it can encourage the schools in that part to improve it should prosper. The Diocesan College and the Huguenot College are both small, and probably they will in the end have to unite with their more powerful neighbours.

The education provided by the colleges is not so good as it might be under more favourable conditions. One at least of them, the South African College, is in every way competent to give as advanced instruction as most colonial universities, and equally with them to promote research; but it is hampered at once by the schools below it and by the university above it. In mathematics, indeed, the general standard of the schools is remarkably high; a few schools maintain a fair standard in science as well, but in literary subjects they are all miserably weak. This is partly due to the absence of any proper system of secondary or of intermediate education. The Education Department is frequently accused of an undue affection for red tape, with which it is said to strangle the more advanced and ambitious schools in the interests of weaker country schools, that have to be kept up to the mark by strict regulations. However that may be, there is no advanced secondary education in the colony. The schools do not

carry their classes beyond the matriculation examination of the university, which thus serves as a general leaving examination, and when their pupils have passed it there is nothing for them to do, if they wish to prosecute their studies further, but to go on to college, however young and crude they may be. So long as the present university system endures it is difficult to foresee any remedy for this. The university does not demand of its candidates for the higher examinations that they should have been trained at a college, and were the schools to develop advanced classes they would merely compete with the colleges in teaching for the intermediate degree examination, the standard of which would be still further lowered. What is wanted is a system of secondary schools entirely independent of any university, the pupils of which would not be sent on to college until they had reached a decent maturity. As things are, the whole educational system of the colony is absolutely subject to the tyranny of external examinations, and for this the university is chiefly responsible.

So unsatisfactory a state of affairs cannot endure much longer. The only radical cure for it is one which Mr. Rhodes attempted to bring about years ago, the institution of a single teaching university in Cape Town. (The eastern province is not yet sufficiently developed to support a separate university, but in view of its great distance from Cape Town the college at Grahamstown might perhaps remain as an affiliated institution until it is strong enough to stand alone.) Such a teaching university Mr. Rhodes would have endowed, and even though, through local jealousies, the chance of his munificence has been lost, his plan remains the wisest and even the most economical. The Government is remarkably liberal in the cause of higher education. It pays, usually up to a limit of 200*l.* a year, half the salary of all professorships or lectureships the institution of which it approves; it pays half the expenses of general maintenance, and issues loans in aid of building schemes on very favourable terms. In the case of colleges which confine themselves to work above the standard of matriculation and have not less than seventy-five matriculated students—*i.e.* at present in the case of the South African and Victoria colleges—the grants in aid of salaries may be increased up to a limit of 350*l.* The public expenditure on behalf of higher education is thus very considerable, but it is dissipated among several centres, and the benefits accruing from it are necessarily less than they would be were it directed to the support of a single teaching university.

Unfortunately, this ideal is even more unlikely of achievement now than it was in Mr. Rhodes's lifetime. Public opinion remains inert, but the colleges have grown, and it would be almost impossible, and probably undesirable, to force them into reluctant amalgamation. Yet something must be done. The country colleges would prefer probably the conversion of the present university into a federal system of constituent colleges, a policy which has, of course, been tried elsewhere, but without much success. In Cape Town, on the other hand, the feeling is growing that, even though other centres may stand aloof, the city itself should do its best to realise Mr. Rhodes's purpose by founding a teaching university. In the South African College it has the means of doing so, and when that institution has completed its present scheme of development its just claim to independence could not be refused. Nothing could be more beneficial to the colony than such a university in Cape Town with well staffed and well equipped professional schools attached to it. Not only would it raise the general standard of education, as no merely examining body can, but it would draw together and train together the best intellects among the youth of the country, and would thus prove an invaluable factor in the work of uniting the races. No doubt it is a costly scheme, and since the Government cannot concentrate its support of higher education, but will have to continue to assist some at any rate of the local colleges, a great part of the burden must fall on private benefactors. But at the Cape itself to arouse enthusiasm for a great ideal should not be difficult, and it may even be hoped that among the men of millions "who live at home at ease," and who are at last beginning to appreciate the dessert of universities, some may be found willing to assist a scheme which is not the less deserving because it is South African.

THE BATOKA GORGE OF THE ZAMBESI.[1]

WHEN I undertook to examine the geological structure of the country around the Victoria Falls on behalf of the council of the British Association, it appeared to me that there were two essential matters on which our information was very inadequate. The first was with respect to the origin of the falls themselves and the singular gorge associated with them, and the second as to the course of the great river for 70 or 80 miles below the falls. The opinion of David Livingstone, stated fifty years ago, that the gorge must have been formed by the sudden opening of a zigzag crack in the earth's crust, had been adopted without question by all subsequent travellers, although hardly anything was known of the cañon beyond the immediate vicinity of the falls.

Before I left England last June, however, a timely store of new information was forthcoming that materially lightened my task. In an able article on "The Physical History of the Victoria Falls" (*Geograph. Journ.*, January), Mr. A. J. C. Molyneux, of Bulawayo, produced strong evidence to prove that the majestic waterfall and its concomitants have been slowly developed by the erosive power of the Zambesi itself. With regard to the course of the river below the falls, unpublished information was most courteously placed at my disposal by the authorities of the British South Africa Co., which showed that a distinguished officer of the company, Mr. F. W. Sykes, the District Commissioner at Livingstone, had succeeded three years ago in penetrating the hitherto unknown country bordering its northern bank for some 40 miles to the eastward of the falls. The report on this journey prepared by Mr. Sykes, and the beautiful photographs by which it was illustrated, were sufficient in themselves to explain the ruling features in the physiography of the district, and incidentally afforded further testimony in favour of Mr. Molyneux's conclusions.

During my own examination of the district in July and August last, I had the inestimable advantage of the personal guidance of Mr. Sykes in my traverse of the country on the northern side of the river from Victoria Falls to Wankie's Drift. In this traverse we were accompanied by Colonel Frank Rhodes,[2] and for part of the distance by Lieut. Burgin, in command of a detachment of native police. The journey entailed a devious and somewhat arduous march of about 120 miles across an almost trackless country, consisting mainly of rugged stony ground covered with low trees. Wankie's Drift appears to lie considerably to the eastward of the position assigned to it on existing maps, its distance in an east-south-easterly direction from Victoria Falls being probably not less than 75 miles as the crow flies.

Our route was roughly parallel to the course of the Zambesi, at first south-eastward for about 20 miles (in a direct line), then toward east-north-east for a further 35 miles, until we crossed the Ungwesi or Kalomo River, and finally east-south-eastward for nearly 40 miles, to the river-crossing at Wankie's. The deep impassable chasms into which all the tributary streams are precipitated as they approach the Zambesi, and the extremely rugged character of the much-dissected ground between them, forbade any passage along the brink of the main gorge except for short distances, and our general line of march was therefore taken beyond the heads of the side-chasms, often many miles from the Zambesi itself. At four places, however, before reaching the Ungwesi, we struck southward to the main river; and at three of these we managed by rough scrambling to descend into the bottom of the gorge. Finding in these places that the ancient lavas of the surrounding plateau—the "Batoka Basalts" of Molyneux—were still, as at the Falls, the only rocks exposed in the gorge, we decided, as time was pressing, to continue along

[1] Abstract of "Report on the Batoka Gorge of the Zambesi and the Country between Victoria Falls and the Confluence of the Deka River," brought before the Geological Section of the British Association at Johannesburg on August 29, by G. W. Lamplugh, F.R.S.

[2] The news, which reached me during the homeward voyage, of the untimely death of Colonel Rhodes at Cape Town on September 21 has overshadowed the otherwise delightful memory of this journey. To have known Colonel Rhodes, the most cheery of travelling companions, at all was inevitably to hold him in affectionate regard. His deep and cultured sympathy in all that pertained to the magnificent Falls, and his efforts to maintain their loveliness unimpaired, deserve the grateful remembrance of all interested in Rhodesia.

the main route until the termination of the basalts was reached. These rocks proved unexpectedly to be continuous to Wankie's, although the "Batoka Gorge" (as it is proposed to name this cañon of the Zambesi) itself ceases 6 or 8 miles above Wankie's, giving place to an open valley with a broad shallow river sprinkled with islets.

On ferrying in a native "dug-out" across the Zambesi at Wankie's we were met by Mr. H. F. Greer, of the British South Africa Co., who holds charge in the district south of the river. Here Mr. Sykes and Colonel Rhodes struck southward to reach the railway at Wankie Coal Mine, 35 miles distant, while Mr. Greer and myself took a westerly course parallel to the Zambesi for about 60 miles, still traversing a basalt-country. We turned aside twice in this westward journey in order to examine the Zambesi valley at places eastward of those reached from the north bank. One of these was at the confluence of the Matetsi with the Zambesi, which is a little below the termination of the narrow gorge; and the other place was about 15 miles farther west, where the structure of the cañon is not materially different from that which it presents in the place where it had been last entered from the northern side of the river.

Mr. Greer having very kindly undertaken to escort me to the headwaters of the Deka River, where previous information had led me to expect that the base of the Batoka Basalts would be found, we then took a south-westerly course to Matetsi Camp. Crossing the railway there, we continued our journey westward, southward, and south-eastward across the upper part of the basin of the Matetsi River, and after some days of hard trekking struck the higher reaches of the Deka, only to find that the interminable plateau-basalts over which the whole of our route had hitherto lain were still the underlying rocks, and that the surrounding country gave no indication of structural change. It had been our intention to return from Deka to the Falls by the old traders' route past Pandamatenka and Gasuma; but as the Bushmen reported that, owing to the exceptionally dry season, no water would be found in Gasuma Vley, this plan became impracticable, and we decided to follow a north-eastward route, parallel to the Deka River for about 60 miles, to the Wankie Coal Mine. Geologically, this proved to be the most interesting part of my journey, and I therefore spent four days at Wankie in further investigation, profiting greatly from the guidance and kind hospitality of the manager of the mine, Mr. J. M. Kearney.

The basalts are cut off abruptly along the lower portion of the Deka valley by a great fault striking approximately north-east, which brings in the sandstones and shales with which the Wankie coal-seams are associated. Some fragmentary plant-remains were collected from the Wankie Coal-measures, and among these Mr. A. C. Seward has recognised Vertebraria, which indicates that the deposits are of Permo-Carboniferous age, as indeed had been previously surmised. Returning by rail from Wankie Mine to Victoria Falls, I spent a few more days in examining the head of the gorge and its surroundings, and was then compelled to leave Rhodesia in order to join the Association at Johannesburg.

The 600 miles of actual trekking that was accomplished embraces a region of some 2000 square miles, of which all except about 80 square miles east of the Deka is underlain by the Batoka Basalts. The full extent of these ancient lava-fields is still unknown, but, judging from information that I obtained, it is likely to be not less than 7000 square miles. Their thickness is also unknown, but in the lower part of the Batoka Gorge, where the original surface of the basalts must have been very considerably lowered by denudation, the Zambesi has sunk for 800 feet further through these rocks without revealing their base. In their prevalent characters they are remarkably uniform, consisting generally of thick bands of close-grained dark-blue rock alternating with red, purple, or ashy-looking amygdaloidal bands which mark off the surfaces of successive lava-flows. These less massive bands frequently show a fragmental structure, and occasionally pass into fine and coarse agglomerates suggestive of volcanic tuffs or ashes; but I think that this structure may represent the brecciation of the solid crust of the lava-flow before its onward movement had ceased, and is not indicative of true ashes. In the whole course of the journey I did not find any trace of an eruptive centre or volcanic orifice, and the rarity of dykes was also remarkable. Neither did I find any interstratified sediments among the basalts in the country traversed, though there appear to be some interstratified red and green beds of shaly aspect in the railway cuttings of the Katuna valley west of the Deka, which I had no opportunity to examine. Like similar "plateau-basalts" in other parts of the world, this immense mass of lava has probably had its origin in "fissure-eruptions," by which a vast tract was flooded under rapidly recurrent flows of high fluidity.

We still lack definite information as to the geological age of the Batoka Basalts; by Mr. F. P. Mennell and Mr. A. J. C. Molyneux they are regarded as most probably Tertiary, while Dr. S. Passarge correlates them with the Loale Amygdaloid, which he considers to be of Secondary age, perhaps Jurassic; but the evidence for either view remains inconclusive.

The surface-deposits of sand, sandy limestone, cavernous quartzite and hematite which locally overlie the basalts in this part of the Zambesi basin, though of considerable interest, must be dismissed for the present with the remark that their mode of occurrence in this region is not favourable to Dr. Passarge's view that they represent a definite order of events. The red sand (equivalent to the "Kalahari Sand" of Passarge, and probably in part to the "Forest Sandstone" of Molyneux) may, indeed, denote a period of conditions different from those now existing; but the limestones and quartzites appear to me to be due to purely local circumstances that still prevail.

Let us now turn to regard briefly the physiography of the region;[1] in which respect that wonderful natural feature, the Victoria Falls, is, of course, the main pivot of interest.

Above the Falls, the Zambesi flows sedately in a broad mature valley with low sides, excavated in the upper portion of the Batoka Basalts. The gentle slopes of this valley are partly buried under ancient desert-sands—the "Kalahari Sand" of Passarge—and all the features point to a long continuance of relatively stable conditions during which the river has done very little erosive work. On the brink of the Falls its bed is still about 3000 feet above sea-level; but at this point, suddenly, with a majestic plunge, the Zambesi begins its impulsive descent from the central plateau, and thereafter tears its way forcefully across the mountainous margin of the continent, through a succession of gorges alternating with relatively placid reaches according to the variable endurance of the rock-masses that lie in its path. It is to this rejuvenation of the river at the present margin of the plateau, and its resultant influence upon certain structures of the basalts, that, as Mr. Molyneux has shown, we owe the magnificent Falls, and not to any catastrophic rending of the earth's crust.

The Batoka Basalts are traversed by a regular and persistent system of close-set joints striking approximately east and west, and are also occasionally fractured in the same direction by still bolder vertical planes, probably representing lines of fault, that are sometimes accompanied by veins of calcite and other minerals. At the surface of the plateau the basalts are much weathered, and this weathering sinks deepest along the joints and fractures, whereby these become the lines of readiest erosion.

The rivers of this country are characterised by the enormous difference that obtains between their volume in the dry and in the wet seasons, a difference which affects the great Zambesi proportionately almost as much as its tributaries. During the shrinkage of the streams, the greater portion of their broad rocky beds is laid bare, and the water is confined within narrow gullies along the joints and lines of readiest erosion, so that for more than half the year it is in these channels only that there is any wearing down of the stream-bed, while in flood-time it is still along these gullies that the water is deepest and most forceful, and that the chief portion of the detritus (astonishingly scanty in these African rivers) is swept. Thus, granting a sufficient gradient, these dry-season channels become deepened and enlarged until they are

[1] This portion of the report was illustrated by lantern slides showing the chief features of the Gorge.

capable of carrying the flood-waters also, and the course of the stream becomes fixed along them. We found striking illustrations of these conditions both in the Batoka Gorge and in the beds of the tributaries in many places. The sudden and acute bends that are so peculiarly characteristic of the Zambesi below the Falls are in this way readily explicable.

A broad ancient river-flat, with low sloping banks on both sides, excavated across the edges of the gently dipping lava-flows, is distinctly traceable for many miles below the Falls, until obscured by the breaking up of the plateau by the gradually lengthening development of the lateral chasms of the rejuvenated tributaries. This flat is comparable in breadth and general aspect to the valley of the Zambesi above the Falls; and the presence of a few rounded pebbles upon it above the brink of the gorge gives further evidence for the former flow of the river over its surface. It is continued southward as a shallow depression in the surface of the plateau for five or six miles from the Falls, and then curves eastward.

It may be mentioned here, as a matter deserving the attention of archæologists, that rudely chipped implements of chalcedony, agate, and jasper are very abundant in many places on this ancient river-platform, and also upon the low rocky hummocks bordering the Zambesi above the Falls. A few of these implements show signs of wear as if by river-action, and may therefore possibly be of considerable antiquity. We found them, here and there, in profusion during the first 20 miles of our eastward journey, but very rarely during the later stages of the trek. A collection of these implements was exhibited at a meeting of the Anthropological Section.

The erratic zigzags of the Batoka Gorge swing to and fro within this broad depression, but without escaping from it. Even within the gorge, the river, still possessing a high gradient, tends to confine itself within narrower limits as it scoops out the less resistant portions of its bed, leaving many abandoned channels, rock-terraces, and spur-like ridges to break the severity of its cañon walls.

Nowhere can these features be better studied than in the left bank of the Gorge, about 7 miles below the Falls, around the confluence of the Songwe, a little tributary which has itself carved out a narrow chasm about three-quarters of a mile long and more than 400 feet deep into the margin of the plateau. As well for its savage magnificence as for its scientific interest, this spot deserves to be visited; and one may be allowed to express the hope that the responsible authorities will undertake the comparatively light work of clearing a track from the Falls, to render it accessible to the tourist.

To one whose first impressions of the Zambesi had been gained from the mile-wide river above the Falls, it was astonishing to find the whole river, at its present low stage, confined at this place within a channel not more than 35 yards in width—bordered, it is true, by a rocky scar, about 150 yards wide, honeycombed with deep "pot-holes," which was evidently submerged during the floods. After seeing it one could understand how the idea has arisen—and still lingers—that part of the Zambesi is swallowed up at the Falls into an underground channel.

But even this is not the narrowest limit within which the great Zambesi can confine itself at low water; for on reaching the bottom of the gorge at the Tshimamba Cataracts, some 20 miles east of the Songwe, we found the whole river raging tumultuously through a water-channel which, at one place, was less than 25 yards in breadth (Fig. 1). This place is apparently the only part of the interior of the Batoka Gorge that was ever penetrated by the white man until Mr. F. W. Sykes's expedition of 1902. His predecessor here was David Livingstone, who in his second book of travels tells how he turned aside on his eastward journey at the rumour of another great waterfall, and was disappointed to find, not a second Victoria Falls, but only a bold cataract, in which the river drops about 20 feet. Nevertheless, the Tshimamba also, were it rendered more accessible, would be well worth visiting, if but to see the mighty river shrunk to this little measure; and one may expect, sooner or later, to find it included within the "grand tour of the Zambesi."

Although the surface of the basalt plateau falls steadily eastward, the Zambesi within its gorge sinks somewhat more rapidly in the same direction, so that while immediately below the Victoria Falls the river is barely 400 feet below the lip of the gorge, this is increased to about 500 feet at the Songwe, to about 600 feet at the Tshimamba, and to 800 feet at the place some 35 miles farther east which we reached from the south bank. Aneroid observations showed a difference of more than 900 feet between the level of the river at the foot of the Falls and Wankie's Drift, which represents the descent of the water in passing through the Batoka Gorge; and until this steep gradient is very much reduced the Zambesi must continue to deepen its channel along the easiest lines before there is time for it to straighten out the angularities of its course.

The results attained by this selective erosion are strikingly exemplified in the immediate surroundings of the Victoria Falls. The wonderful Chasm, in places only 80 yards wide, into which the broad river is here precipi-

From a photograph by Mr. F. W. Sykes.

FIG. 1.—The Gorge immediately below the Tshimamba Cataract. The depth of the cañon here is about 600 feet. The Zambesi, in the foreground, is confined in a channel from 20 to 25 yards wide. Note how the strong jointing of the basalt governs the course of the river and tends to produce zigzags in the low-water channel.

tated, owes its chief features to the presence of an east and west vein, probably a fault-plane, that cuts vertically through the basalts. This vein, which I found to be well exposed in the steep Recess or gully at the eastern end of the Chasm, is partly filled with calcite and other soft vein-stuff, and the rock adjacent to it is shattered and readily decomposed. When the falls, in receding northward, struck upon this vein, they readily hollowed out a transverse trench across the whole breadth of the river, from which the waters escape southward through a single narrow channel. But, having passed this easy place, it is becoming increasingly difficult for the shallow river to support a fall of its full width, and consequently the wearing back of the lip is at present progressing most rapidly in a comparatively narrow space at its western margin. Here the "Leaping Water" pours a strong flood perennially into the corner of the Chasm, and may eventually concentrate the whole of the river into its trough, unless, as Mr. Molyneux has suggested, the deep oblique cleft that is being rent across Cataract Island should gain precedence

in the backward race. The narrowness of the cañon below the falls, as compared with the breadth of the river above them, shows that only by such concentration has the Zambesi been enabled to tear out its gorge so far back into the plateau.

Mr. Molyneux has rightly laid stress on the behaviour of the tributaries as proof of the erosive origin of the Batoka Gorge. Above the Falls the tributaries have so nearly reached their base-level relatively to the Zambesi that they hold deep back-waters where they join the main river, of which the Maramba, 2 miles from the Falls, presents a good example. But below the Falls they have at first been left in shallow open "hanging valleys," high above the main artery; and thus rejuvenated by a sheer drop of 350 feet or 400 feet, each little stream has begun to work vigorously backward into the

From a photograph by Mr. F. W. Sykes.

FIG 2.—Kalonga's Cleft on the Karamba River. The walls are about 300 feet high.

plateau along its own line of drainage. Each waterfall tends to recede farther and farther within its own precipitous rift as we followed the Zambesi downward, so that while at first it was possible to round the heads of these by a detour of a few hundred yards, we found that farther east not only do they extend far back into the plateau, but many minor clefts branch out from them, rendering the country a maze of dangerous chasms. In these waterfalls and rifts the salient features of the main gorge are often reproduced in miniature. The most remarkable example that we visited occurs on the Karamba, a stream which joins the Zambesi about 35 miles east of the Falls. Some 5 miles above its junction with the Zambesi this stream drops by a waterfall from its open shallow valley into a gloomy recess, from which it escapes by swerving at a right angle between nearly vertical rock-walls, 300 feet in height, through a cleft only 15 feet to 20 feet in breadth (Fig. 2).

If further proof for the erosive origin of the Batoka Gorge be needed, I would direct attention to the gradual falling off in the angle of slope of its sides as we descend the river. At the Falls, where the gorge is freshly cut, its walls are practically vertical; but a few hundred yards below they are already beginning to show the effect of weathering by a slight recession of their crest-line and by indications of terracing along the planes of stratification. At the Songwe confluence, 7 miles farther down, this recession and terracing have become so pronounced that the average angle of slope from base to crest is reduced to 60° or less; at the Tshimamba, about 30 miles below the Falls, it is no more than 35°; and at the mouth of the Karamba, 12 miles farther east, the sides of the gorge have been weathered down into bushy slopes, broken here and there by inconspicuous bars of crag, with an average inclination of about 30°, which is also the character of the cañon at the place where it was visited still farther eastward.

If time had permitted, I should have liked to discuss the curious difference between the broad basin of the Matetsi and the narrow trough of the Zambesi within the basaltic plateau, which presents an important problem in the physiography of the region, especially when we remember that the Batoka Gorge terminates at a short distance above the confluence of the Matetsi; but this would open up too wide a subject for the present occasion.

In the face of all the evidence we must conclude—not without a tinge of regret—that the Batoka Gorge can no longer be allowed to stand apart, a unique curiosity, among the valleys of the earth—that no exceptional forces have been brought into action to produce its wonders and its loveliness—but that the everyday effects of river and rain, with time—that indispensable factor to the geologist—a very long time—are ample to explain all its marvels, as they have already explained the marvels of many another noble cañon of the world.

I must not let pass this opportunity of expressing my gratitude for the kindness shown to me by the officers of the British South Africa Company in Rhodesia and also in London, by the engineers of the Wankie Coal Mine and of the Rhodesia railways, and by many other friends in Rhodesia. To Mr. F. W. Sykes I am peculiarly indebted for removing difficulties that, except for his self-sacrificing cooperation, might have proved insuperable. G. W. L.

INDIAN DEEP-SEA HOLOTHURIANS.[1]

THE most recent addition to the list of publications issued by the Indian Museum, Calcutta, deals with a collection of deep-sea Holothurians made by the survey ship *Investigator*, which has rendered valuable service in the interests of deep-sea research. The extreme utility of this work, which will help to elucidate many of the problems connected with deep-sea life, is enhanced by the fact that the investigations have been carried on over comparatively unknown ground, so far as the great depths are concerned.

The area examined by the *Investigator* is a comparatively wide one, and ranges over the northern part of the Indian Ocean from the Persian Gulf to the east side of the Bay of Bengal.

Most of the deep-sea expeditions appear to have confined their labours to the Atlantic and Pacific Oceans, and even the *Challenger* did not touch the northern part of the Indian Ocean. The *Siboga* Expedition reached the extreme south-eastern portion of the *Investigator* area, and a comparison of the *Siboga* Holothurians with those in the paper under notice provides an interesting study, and, incidentally, confirms the opinion that a knowledge of the distribution of deep-sea forms derived from an examination of isolated areas is apt to be misleading.

Of the seventy-five species and varieties described in the report, no less than sixty are new to science. The Synallactidæ appear to be the predominant forms amongst the deep-sea Holothurians of the Indo-Pacific region, both

[1] "An Account of the Deep-sea Holothurioidea collected by the Royal Indian Marine Survey Ship *Investigator*." By R. Kœhler and C. Vaney. Pp. 123; 15 plates. (Indian Museum, Calcutta, 1905.)

with regard to species and individuals. In the *Investigator* collection twenty-nine species are placed in this family, and the Molpadiidæ and Synaptidæ are well represented. The authors have found it necessary to form ten new genera, and a seventh family—the Gephyrothuridæ—has been added to the Aspidochirotæ.

There was a large number of specimens of the genus Pelopatides and its allies in the collection, and the authors were given an opportunity of revising the genus. Five new genera were established to receive forms closely related to Pelopatides. Dendrothuria is peculiar in having dendrochirote tentacles and an enormously developed pharynx. Pseudothuria has no single distinctive characteristic, but all its characters taken together separate it from the neighbouring genera. The genus Allopatides has been formed from a single specimen, and its main difference from Pelopatides appears to be the richly dendritic form of the spicules. It may be doubted whether this difference is of generic value, especially as some species of Pelopatides also possess branched spicules not differing greatly from those in the new genus; the difference appears to be merely one of degree. The genera Perizona and Bathyzona have been formed mainly with regard to the position of the pedicels. Five other new genera are also described.

The new family—Gephyrothuridæ—is founded on two specimens which differ from all other Aspidochirotes in the possession of ambulacral appendages on the bivium only. In external appearance this form somewhat resembles the Molpadiidæ.

The collection includes some forms described by Walsh in 1891; the authors have deemed it necessary to remove all his species to other genera.

With every increase in our knowledge of the deep-sea fauna, it becomes more possible to formulate with some degree of completeness definite ideas as to the distribution and the mode of evolution of the deep-sea forms; and the work under notice is of importance in this respect, suggesting as it does many interesting points in zoological distribution.

Comparing the *Siboga* list of deep-sea Holothurians with that of the *Investigator*, it is surprising to find that in the two collections from adjacent areas there are only six species common to both. The two gatherings are almost entirely dissimilar with regard to the species present, but an examination of the genera shows a close similarity. It is perhaps noteworthy that those species common to both districts are not confined to the eastern portion of the *Investigator* area, as one might expect, but are scattered equally throughout it.

Of the fifteen species previously described, six are Atlantic and five Pacific forms; there are three species in the collection the distribution of which has hitherto been limited to the Atlantic.

The descriptions are clear and not too scanty, as is often the case, and the plates are good. Altogether the authors have made a most valuable contribution to the subject, and they appear to have done extremely well with material that was evidently not in the best state of preservation.

J. P.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

Oxford.—The following decrees were approved by Convocation last Tuesday:—The curators of the University Chest were authorised to pay a sum not exceeding 150*l*. to the professor of botany to enable him to provide for the teaching of forest botany, until the appointment of a Sibthorpian professor under the new statutes of St. John's College.

Mr. Henry Balfour, Fellow of Exeter College, was re-appointed curator of the Pitt-Rivers museum for seven years at a stipend of 200*l*. a year, and the annual grant of 200*l*. to the museum was renewed for seven years.

An examination will be held next February for a Radcliffe Travelling Fellowship of the annual value of 200*l*., and tenable for three years. Candidates must have qualified for the degrees of B.A. and M.B., and have been placed in the first class in a university examination, or have gained a university prize. Names should be sent to the Regius professor of medicine.

The following is a list of the probationers for the Indian Forest Department and the Sudan nominated in 1905, with the colleges to which they are now attached:—C. W. Armstrong, scholar of Jesus College, Oxford; G. C. Clarence, Magdalen College, Oxford; T. Clear, science exhibitioner of Balliol College, Oxford; C. G. E. Dawkins, Balliol College, Oxford; C. C. Gaunt, exhibitioner of St. John's College, Oxford; H. S. Gibson, Trinity College, Oxford; H. M. Glover, mathematical demy of Magdalen College, Oxford; J. Gunn, Edinburgh University, now at St. John's College, Oxford; J. K. Hepburn, Queen's College, Oxford; N. W. Jolly, Adelaide University, now at Balliol College, Oxford (Rhodes scholar); W. A. H. Miller, St. John's College, Oxford; A. J. W. Milroy, Christ Church, Oxford; A. A. F. Minchin, Exeter College, Oxford; R. L. Robinson, Adelaide University, now at Magdalen College, Oxford (Rhodes scholar); E. A. Smythies, Christ's College, Cambridge, and Balliol College, Oxford; and G. C. Wilson, Queen's College, Oxford.

The Government of Mysore has sent two forestry students, M. M. Machaya and B. V. Ramaiengar, both of St. John's College, Oxford, and of Madras University.

Cambridge.—The Forestry Syndicate has now issued its detailed report on the scheme for establishing a diploma of forestry. It is proposed that a committee of the Board of Agricultural Studies be appointed to be called the forestry committee, the duty of which shall be to manage the examinations in forestry and to direct the instruction and training of candidates for the diploma. Details as to the constitution and duties of the committee are printed in this week's *Reporter*.

The general board of studies has appointed Mr. J. G. Leathem, St. John's College, university lecturer in mathematics from Christmas, 1905, until Michaelmas, 1910, and has re-appointed Mr. C. T. R. Wilson, Sidney Sussex College, university lecturer in experimental physics from Christmas, 1905, until Michaelmas, 1910; both these appointments have been confirmed by the special board for physics and chemistry.

Mr. A. C. Seward, of Emmanuel College, has been appointed chairman of the examiners for the natural sciences tripos, 1906.

The late Mr. G. R. Crotch, of St. John's College, some years ago left his collections of insects and his books to the Museum of Zoology, and also after the death of certain relatives his personal estate to the same museum. His brother, Mr. W. D. D. Crotch, who recently died, has left his residuary estate, the value of which is about 8000*l*., to the same museum.

Sir Alexander R. Binnie will distribute the prizes at the Merchant Venturers' Technical College, Bristol, on Thursday, December 21.

The Public Schools Science Masters' Association will meet for the annual conference on January 20, 1906, at Westminster School. The president for the year, Sir Oliver Lodge, will speak on the place of science in general education. Papers will be read upon the army examination and on the possibility of introducing a comprehensive syllabus of science teaching within the time limits of a classical curriculum. After the conference there will be an exhibition of scientific apparatus by various makers in the new science buildings of Westminster School.

The North of England Education Conference will be held at Newcastle-upon-Tyne on Friday and Saturday, January 5–6, 1906. Among the subjects to be discussed are the following:—The teaching of elementary mathematics, paper by Prof. R. A. Sampson, F.R.S.; openers of discussion, Dr. Jude and Mr. J. H. Kidson. Regulations for secondary and higher elementary schools, papers by Mr. W. Edwards and Mr. W. J. Abel; openers of discussion, Miss M. Moberly and Mr. P. M. Greenwood. Organisation of evening classes, papers by Principal J. H. Reynolds and Mr. J. Crowther; opener of discussion, Mr. A. M. Ellis. Physical Training, papers by Prof. T. Oliver and Captain H. Worsley-Gough; openers of discussion, Dr. Ethel Williams and Captain F. C. Garrett. All com-

munications with reference to the conference should be addressed to the hon. secretaries, Mr. Alfred Goddard and Mr. F. H. Pruen, Education Offices, Northumberland Road, Newcastle.

SEVERAL changes have taken place, we learn from *Science*, in the staff of the research laboratory of physical chemistry of the Massachusetts Institute of Technology. Prof. W. D. Coolidge has accepted a position in the technical research laboratory of the General Electric Company at Schenectady. To Prof. Coolidge has been due in large measure the development of one of the most important lines of work in progress in the research laboratory of the institute—the investigation of the conductivity of aqueous solutions at high temperatures. Mr. Yogoro Kato, who has also been engaged on the conductivity investigation for two years, has accepted a position in the Technical High School of Tokio, where he will have charge of the work in electrochemistry. Dr. Wilhelm Böttger will return as privatdocent to the University of Leipzig, at which he will conduct one of the laboratory courses in analytical chemistry. In place of these retiring members, Messrs. William C. Bray, Guy W. Eastman, Gilbert N. Lewis, and Edward W. Washburn have been appointed to the research staff.

AT the distribution of prizes to the students of the Mechanics' Institute, Crewe, on November 22, Sir Oliver Lodge delivered an address. He emphasised the importance of the study of pure science and the application of its broad principles, whereby it is possible to make discoveries and to ascertain facts which are not known to the human race. After all the ages of the human race there are innumerable facts which we do not know, and it is now and then given to a man here and there to find them out and pass them on as common property never more to be lost. Sir Oliver Lodge went on to say he does not believe that a thing which really exists can go out of existence. There is an infinitude before us, and it behoves us to realise that and see to it that we fit ourselves for what is to come. We are parts of an industrial organism, parts of a much larger organism, the universe, and in the universe there is one great law of evolution, of growth, and development. The universe is not yet perfect; it is our privilege to help in the process of making it more perfect. Things will not be done on this planet unless we help to do them; we are agents for helping in the process of evolution. Errors or mistakes may cause dislocation or calamity in the great scheme. We have the power of causing dislocation or calamity by errors, or by living strenuous self-sacrificing lives we have the power of cooperating in the great scheme of helping towards the fruition, development, growth, and progress of the universe of which we are an infinitesimal part.

THE inaugural address delivered by Dr. B. C. A. Windle, F.R.S., president of Queen's College, Cork, at the opening of the session, is given the first place in the current number of the *University Review*. Dr. Windle deals in an exhaustive manner with the subject of examinations in Ireland and with the university question. Four deadly errors, he maintains, have long affected England and Ireland. These errors are that acquisition of knowledge and education are synonymous terms; that education—as apart from mere knowledge—can be easily, nay, more, can only be tested by examination; that a degree is in itself an object of value; and that a degree means the same however and wherever it may have been acquired. Dr. Windle regards examinations as an evil, but at present a necessary evil, and proceeds to discuss the objects such examinations should have in view. By means of an examination, Dr. Windle explains, an endeavour is made to ascertain whether the candidate has acquired the necessary knowledge of facts to enable him to proceed to a further stage of learning or—at the end of his course—a sufficient knowledge of his profession to be trusted to go out into the world and practise it independently. An examination is intended, moreover, to ascertain whether a student has acquired the proper methods of gaining and applying knowledge. To secure efficient examinations, the article lays it down, every teacher should take a large share in any examination which his students may have to confront, but the judgment of the teacher should be supported or corrected by the assistance of an external examiner. The conclusion of the article is that there is at present in Ireland, for the great majority of its inhabitants, "a university system which almost necessitates a method of examination which is harmful in its effects on education; a method which leads to subterranean complaints and accusations, which, though they may be, and almost invariably are, false, are none the less injurious to education generally; a method for which, indeed, no excuse can be urged except the excuse that the system arises out of the necessities of a position which never ought to have been created."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, Received September 28.—"Researches on Explosives." Part iii. Supplementary Note. By Sir Andrew **Noble**, Bart., K.C.B., F.R.S.

Since communicating to the Royal Society "Researches on Explosives," part iii., the author has succeeded in obtaining the paper (*Preuss. Akad. Wiss. Berlin Sitz. Ber.*, vol. v. p. 175) by Messrs. Holborn and Austin on the "Specific Heat of Gases at High Temperatures."

The attention of these investigators has been specially directed to carbonic anhydride, and their researches show a considerable (but rapidly decreasing) increment in the specific heat of CO_2 with increase of temperature.

If we suppose the same law of increment which appears to rule up to 800° C. to remain unaltered up to 1300° C., the increments at that temperature would vanish, and, if this be so, the author finds that the specific heat of CO_2, at constant volume, should be taken at 0·2111.

He has therefore re-calculated the specific heats given in his recent paper, and as the specific heats of the exploded gases at constant volume are reduced, the temperatures of explosion given in his paper should also be reduced.

The temperatures the author gives have been obtained by two different methods, firstly, by dividing the heats determined by the calorimeter by the specific heats, and, secondly, by using the equation of dilatibility of gases, and determining the temperature from

$$t = p - p_0/0{\cdot}00367p_0 \qquad (1)$$

where p is the pressure in atmospheres obtained from the explosion, and p_0 the pressure in atmospheres when the volume of gases generated is reduced to 0° C. and 760 mm. bar. pressure.

The differences of the results are very remarkable.

Taking, for example, cordite as an illustration, it will be seen that for the four highest densities given the temperatures derived from the two methods are but slightly different. At the higher density (0·5) the temperatures are 5275° C. and 5263° C., the higher being that derived from equation (1); at density 0·45 the temperatures from the two methods are identical, at density 0·40 the temperatures are 4902° C. and 4970° C., the lower temperature being from equation (1), but after density 0·35 the temperatures derived from equation (1) fall very rapidly.

The same general results are observable in the other two explosives experimented with, and it should be noted that in all three explosives, at the highest densities, the temperatures given by equation (1) are greater than those obtained by the second method.

The figures for the three explosives are given below, the temperatures obtained from $\frac{\text{units of heat}^1}{\text{specific heats}}$ being given in italics.

Cordite.

D=0·50	D=0·45	D=0·40	D=0·35	D=0·30	D=0·25

D=0·15	D=0·10	D=0·05
2680°	2520°	2400
3345	*3295*	*3255*

If these figures be examined, it will be noted that in each explosive at the higher densities the temperatures obtained by the two methods are nearly identical, those determined from equation (1) being the higher, but as the density of charge is decreased the difference at the very low densities is remarkable; some of this difference is doubtless attributable to the slow burning under feeble pressures, and to the rapid cooling, by communication of heat to the walls of the explosive vessel during the ignition of the charge, but it is impossible to ascribe the whole difference to this cause, and the author can only suggest that the explanation is to be sought in the probable dissociation of the carbonic anhydride and aqueous vapour at low pressures, this dissociation being prevented wholly or partially by the very high pressures at the higher densities.

Various substances such as carbon, metallic platinum, tantalum, osmium, and titanium have been placed in the charge, and all have been more or less fused and volatilised during the small fraction of a second to which they were exposed to the maximum heat.

A great part of the titanium was recovered in a fused crystalline condition.

Osmium and thin platinum foil were volatilised, and thick sheet platinum was recovered in the form of a button.

Received October 6.—"On the Isolation of the Infecting Organism ('Zoochlorella') of *Convoluta roscoffensis*." By F. **Keeble** and Dr. F. W. **Gamble**. Communicated by Prof. S. J. Hickson, F.R.S.

The authors have obtained experimental proof that the green cells (Zoochlorellæ) which occur in the superficial tissues of the turbellarian *Convoluta roscoffensis* arise in the body as the result of an infection.

Like those of previous investigators (Haberlandt), the authors' attempts to cultivate the green cells isolated from the animal have failed. Indeed, the evidence points to the conclusion that the green cells, once having entered into the body of the animal, lose all power of separate existence. Therefore, in order to solve the problem of the nature of the green cells, the authors were compelled to attack it at the other end, viz. to attempt to discover the organism *before* its entrance into the body.

From their observations on the normal course of appearance of the green cells in the bodies of just-hatched Convoluta, the authors were led to expect that the precursors of the green cells would be discovered on or in the capsules in which the eggs of Convoluta are laid. This proved to be the case. By the isolation of such capsules green colonies of a motile organism were obtained, and the organism was proved to have the power of infecting young, colourless Convolutas, hatched under sterile conditions, and of giving rise in these animals to green cells identical with those which occur in the normal adult.

The infecting organism is in its active state a unicellular four-ciliate alga. It has a single basin-shaped chloroplast occupying the greater part of the cell, an eccentrically placed plate-like eye spot, and a large octagonal pyrenoid at the posterior end of the body. The motile cells frequently come to rest and surround themselves with a thick striated wall. They may also in this resting stage undergo vegetative division, giving rise to a "palmella" condition.

These characters point to the membership of the infecting organism with the Chlamydomonadineæ.

Faraday Society, October 31.—Lord Kelvin, president, in the chair.—Alternate current electrolysis: Prof. E. **Wilson**. Experiments (*Roy. Soc. Proc.*, vol. liv. p. 407) made with platinum plates in dilute sulphuric acid show that of the total energy supplied to the cell in a given time, more is returned to the source when the frequency is high than when it is low, the maximum coulombs being of the order 0·0006 per sq. cm. in each case. If the quantity of electricity be plotted coordinately with the E.M.F. of electrolysis it is found that at the higher frequency, for about the same maximum coulombs, the curve has relatively a smaller area, such reduction being probably brought about by the greater reversibility. An experiment made at an intermediate frequency when the maximum coulombs were 0·0000023 per sq. cm. gave a still higher value for the proportion of the total energy which is returned to the source, demonstrating that the magnitude of the maximum coulombs has an important effect. When a metal is dissolved in an electrolyte by alternate-current electrolysis, the amount dissolved in a given time at a given current density is smaller at high than at low frequency. Besides this chief conclusion there are indications of other important effects. A complete investigation would need to take accounts of the density and temperature of the electrolyte, and possibly of other conditions.—Alternate current electrolysis as shown by oscillograph records: W. R. **Cooper**. Although polarisation is of the nature of capacity in an alternate current circuit, there is a considerable difference. What might be termed the E.M.F. of a condenser rises and falls as rapidly as the applied pressure, but although the E.M.F. of polarisation may rise as rapidly as the applied pressure, it falls more slowly, with the result that under suitable conditions the current curve may depart very considerably from the sine form. Actual oscillograph records are reproduced in support of this view. In considering the subject it has been very generally assumed that the current follows a sine curve. Since the curve obtained depends very much on the conditions of the experiment, it is necessary to define the conditions very carefully before conclusions can be drawn from different experiments. Oscillograph records of electrolytic rectification were also shown.—Note on the crystalline structure of electro-deposited copper: Prof. A. K. **Huntington**. In Mr. Cowper-Coles's process for making copper wire electrolytically a spiral scratch or groove on the mandril causes the copper deposited on it to part so easily that a long ribbon can be obtained. The author's explanation is that the direction of the lines of crystallisation of an electro-deposited metal is the same as in a casting made on surfaces having the same inclination, *i.e.* the crystals form at right angles to the surface on which the deposit or the casting is made.—Some observations respecting the relation of stability to electrochemical efficiency in hypochlorite production: W. P. **Digby**. The author commenced by directing attention to the fact that in all electrolytic methods of producing hypochlorite solutions, only a small portion, rarely more than 18 per cent., of the chlorine usually present in the form of chloride is converted into hypochlorite; and he suggested that the amount of available chlorine produced from a sodium chloride solution depends upon the relation which the amount of unconverted sodium chloride actually present between the electrodes bears to the current density.

Entomological Society, November 1.—Mr. F. Merrifield, president, in the chair.—*Exhibitions.*—(1) *Panurgus morricei*, Friese, a species of bee new to science taken near Gibraltar, of which it was remarkable that, whereas the species of this genus are wholly black, in this species the ♂ face entirely, and the ♀ partly, was bright yellow, the legs partly yellow, and the abdomen spotted down each side, somewhat as in Anthidium; and (2) the unique type specimen of *Eriades fasciatus*, Friese, a ♂ of the Chelostoma group taken at Jericho in 1899, in which again, while all its congeners are practically unicolorous, the abdomen is brightly banded like a wasp: Rev. F. D. **Morice**. A discussion followed as to the reason of the peculiar coloration in the species under review, the exhibitor pointing out that the colour mimicry in this species could not be due to parasitism, both Panurgus and Eriades being industrious genera.—A ♂ specimen of the earwig *Forficula auricularia* taken at Warwick in September last, with a drawing of the cerci (forceps), which were very abnormal, the broader basal part of the two appearing to be more or less fused together, while the legs of the forceps also were jointed to the basal part: W. J. **Lucas**.—Various interesting insects from Guatemala recently received from Señor Rodriguez, including *Heterosternus rodriguezi*, Cand., *Pantodinus klugi*, Burm., *Plusiotis adelaida*, Hope, and a species of Orthopteron greatly resembling a dead withered leaf, possibly a new species of Mimetica: G. C. **Champion**.—Two species of Coleoptera new to the British

Islands, *Loemophilus monilis*, F., taken in the neighbourhood of Streatley, Berks, and *Dacne fowleri*, n.sp., from Bradfield, with specimens of *D. humeralis* and *D. rufifrons* for comparison: Norman H. **Joy.**—A specimen of a new Agathidium discovered last year in Cumberland, and now taken by the exhibitor in Durham, and a series of *Prionocyphon serricornis* from the New Forest with a drawing of the larva, which he had found under water in the boles of trees, but appeared to emerge for pupation and descend into the ground: H. St. J. **Donisthorpe.**—Preparations of the scents of some African butterflies collected with the assistance of Dr. G. B. Longstaff during the recent visit of the British Association, together with examples of the species investigated: Dr. F. A. **Dixey.**—*Papers.*—A contribution towards the knowledge of African Rhopalocera: P. I. **Lathy.**—A new species of the hymenopterous genus Megalyra, Westwood: J. Chester **Bradley,** Ithaca, N.Y., U.S.A.

Linnean Society, November 2.—Prof. W. A. Herdman, F.R.S., president, in the chair.—Exhibition of the tails of trout and grayling to show the heterocercal origin of the homocercal tail, by means of the hypural bones which balance the vertebra turning upward towards the upper lobe: Rev. G. **Henslow.**—Plant œcology, interpreted by direct response to the conditions of life: Rev. G. **Henslow.** Plant geography and plant surveying—that is, phytotopography—comprise records of the fluctuating distribution of species within definite areas, and associations, the result of natural selection. Œcology proper, or the physiology of plant geography, imply what has been defined by Prof. Tansley as "the study of the vital relations of organisms to their environment." These include the origin of adaptive structures, as varietal, specific, and generic characters, by means of the protoplasmic response to what was formulated by Darwin as "the direct action of the conditions of life, leading to definite results, whereby new subvarieties arise without the aid of natural selection."

Royal Microscopical Society, November 15.—Mr. G. C. Karop, vice-president, in the chair.—Lucernal and solar microscopes by Adams presented to the society: W. E. **Baxter.**—Focusing magnifier made by Messrs. Taylor, Taylor and Hobson: Dr. **Hebb.** The magnifier was a small photographic auxiliary intended for focusing purposes, being placed against the ground-glass screen of the camera to magnify the image and examine its definition.—A new turntable invention: A. **Flatters** and W. **Bradley.** The turntable was driven by clockwork, and was designed for turning oval cells and ringing oval mounts of any proportions from 0″ to $3'' \times 1\frac{1}{4}''$. By the use of the instrument it was also possible to run a ring round a needle point, strike a straight line, or turn circles.—Exhibition of dissections of the tsetse-fly and its trypanosomes: W. **Baker.** Mr. Baker said that, in addition to the slides illustrating the anatomy of the tsetse-fly, there was a specimen of the larva of Ochromyia, also from Africa, together with the perfect insect. The larva lives in the sandy earth, and attaches itself to the flesh and sucks the blood of the natives, causing very troublesome wounds. There was likewise a specimen of the ova of *Schistosoma sinensis* found in the body of a Chinaman who died at Singapore.

Chemical Society, November 16.—Prof. R. Meldola, F.R.S., president, in the chair.—Condensation of ketones with mercury cyanide: J. E. **Marsh** and R. De Jersey **Fleming-Struthers.** Acetone added to a solution of mercury cyanide in aqueous caustic soda gives a white precipitate, $Hg_4C_5H_4ON_2$, which dissolves on further addition of acetone. The reaction forms a good test for acetone applicable in presence of alcohol. The reaction appears to be confined to ketones containing the group $.CO.CH_3$.—Silicon researches, part ix., bromination of silicophenylimide and -amide, and formation of a compound including the group (SiN): J. E. **Reynolds.** Silicotetraphenylamide interacts quite regularly with about six atomic proportions of bromine in benzene. In the first stage bromine removes one of the aniline residues, and there remains a substituted guanidine in solution. This is then attacked with the formation of a soluble di-substituted di-imide. The substituted di-imide finally reacts with one molecular proportion of bromine, giving the compound $SiN.C_6H_3Br_2$.—Application of the microscopic method of molecular weight determination to solvents of high boiling point: G. **Barger** and A. J. **Ewins.** The apparatus used with low boiling solvents is modified by the addition of a "hot stage," whereby the tubes can be maintained at about 90° C.—Green compounds of cobalt produced by oxidising agents: R. G. **Durrant.** The conclusions arrived at are that these substances most probably all contain the nucleus $=Co.O.Co=$, on the persistence of which depends the green colour.—Dunstan, Jowett and Goulding's paper on "the rusting of iron": E. **Divers.** The author rejects the "hydrogen peroxide" theory of rusting advanced by Dunstan and his collaborators, and suggests instead that the active agents are the oxygen and the hydroxyl ions present in the water, the action being represented thus, $(O_2+2H.HO)+4Fe+2O_2=4HO.Fe:O$. In reply, Prof. Dunstan pointed out that the view expressed by Dr. Divers is not intelligible unless it amounts to what is virtually the hydrogen peroxide theory, which accounts for the inhibiting effect of potassium dichromate, as well as of alkalis, on the formation of iron rust in presence of water and oxygen.—Researches on the freezing points of binary mixtures of organic substances; the behaviour of the dihydric phenols towards *p*-toluidine, α-naphthylamine, and picric acid: J. C. **Philip** and S. H. **Smith.** The freezing-point curves indicate the existence of several new compounds of the above substances. These are shortly described.—Synthesis of tertiary menthol and of inactive menthene: W. H. **Perkin,** jun.—The synthetical formation of bridged rings, part ii., some derivatives of di*cyclo*butane: W. H. **Perkin,** jun., and J. L. **Simonsen.**—Optically active reduced naphthoic acids, part i., dextro-$\Delta^{2(\text{or } 3)}$-dihydro-1-naphthoic acid: R. H. **Pickard** and A. **Neville.**—Hydrizino-halides derived from oxalic acid: D. A. **Bowack** and A. **Lapworth.**—The action of nitrogen sulphide on organic substances, part iii.: O. C. M. **Davis.** The investigation of the action of nitrogen sulphide on the aldehydes has been continued, and it has been found that the reaction is not so general as was expected.—The action of nitrogen sulphide on organic substances, part iv.: F. E. **Francis.** Nitrogen sulphide acts on acetic and propionic acids at their boiling points with the liberation of sulphur dioxide and smaller quantities of nitrogen, and the formation of the corresponding amides and di-amides.—Tetrazoline, part iii.: S. **Ruhemann** and R. W. **Merriman.**

CAMBRIDGE.

Philosophical Society, October 30.—Prof. Marshall Ward, president, in the chair.—On a well-sinking at Graveley, near Huntingdon: Rev. O. **Fisher.** Graveley is in an extreme western corner of Cambridgeshire. The well is 154 feet above O.D. It was begun in the spring of 1905 in Boulder-clay, which proved to be 50 feet thick. The Oxford-clay was then encountered and pierced through 252 feet. A bed of Oolitic Limestone was next met with, and punched through a foot and a half. Another foot of clay brought the auger to a second bed of rock, and no supply of water having been obtained, the work was abandoned.—On a portable gold-leaf electrometer for low or high potentials, and its application to measurements in atmospheric electricity: C. T. R. **Wilson.** The electrometer has an outer and an inner case; the latter is maintained by means of a quartz Leyden jar at a positive potential which gives a convenient deflection when the gold leaf is earthed; about 60 volts is generally convenient. If the potential of the inner case is called V, then the instrument is suitable for measuring potentials, positive or negative, in the neighbourhood of zero, and also positive potentials differing by not more than a few volts from 2V. The displacement of the leaf for a change of potential of 1 volt is the same in either case. For convenience in charging the gold leaf to any desired potential, and for other purposes, there is attached to the instrument a small cylindrical condenser of variable capacity, consisting of a sliding tube kept at a constant negative potential by means of a quartz Leyden jar and a rod concentric with the tube fixed to the terminal of the gold leaf. The instrument may be applied to the study of the atmospheric potential gradient at the earth's surface and the earth-air current.

—Contributions to the knowledge of the tetrazoline group: S. **Ruhemann** and R. W. **Merriman**. The authors have continued the study of tetrazoline (see *Trans. Chem. Soc.*, 1902, lxxxi., 261) especially with the view of determining the constitution of the two compounds (previously described) which are formed by the action of methyl iodide on tetrazoline. They show that the one substance, $C_3H_7N_4I_3$, is the additive compound of the other, $C_3H_7N_4I$, and point out the resemblance between the former compound and the additive product of diazobenzene chloride with iodine.—The action of radium and other salts on gelatin: W. A. D. **Rudge**. The author has made experiments with various metallic salts, and finds that those of barium, lead, and strontium produce effects upon sterilised gelatin exactly similar to that caused by radium preparations, and comes to the conclusion that the "growth" observed is not of vital origin, and that the effect obtained by the radium salt is probably due to the large proportion of barium which it usually contains.—A suggestion as to the nature of the "walnut" comb in fowls: W. **Bateson** and R. C. **Punnett**.—The absence of isomerism in substituted ammonium compounds: H. O. **Jones**.

EDINBURGH.

Royal Society, November 6.—Prof. Crum Brown, vice-president, in the chair.—The conductivity of concentrated aqueous solutions of electrolytes, part i.: Prof. J. **Gibson**. When the ratio of the specific conductivity to the concentration measured in grams equivalent per cubic centimetre was plotted against the concentration, curves were obtained concave upwards. When, however, the concentration was measured in grams equivalent per gram, the corresponding graphs became in many cases accurate straight lines, and in most others straight lines over a considerable range of concentration. The point of maximum conductivity, when determinable, lay within this straight line portion. There were a few exceptions to the rules just stated. For example, the graph for zinc chloride was nowhere straight, but was concave upward.—The Tarpan and its relationship with wild and domestic horses: Prof. **Ewart**. The paper was a contribution to the important and difficult question of the ancestry of our domestic breeds of horses. The Tarpan, first described by Gmelin about 1740, had usually been considered as the wild ancestor of the horses of Europe; Dr. Nehring regarded it as the last survivor of the prehistoric European horse, modified by infusion of domestic blood, while Pallas and others thought it might very well be the offspring of escaped domestic horses. After a comparison of the characteristics as to hair, tail, mane, and skeleton of Tarpan and other breeds, Prof. Ewart proceeded to describe the result of his recent experiments on cross-breeding. Bearing in mind the fact established by previous experiments, that the crossing of carefully selected forms sometimes reproduced remote types in all their original purity, he selected a Shetland pony mare which seemed to be a blend of at least three varieties, resembling the wild horse of the Gobi Desert in the head, the forest variety in the mane, tail, and trunk, and the Celtic pony in the limbs and hoofs. This mare was crossed with a black Welsh pony. The first foal failed to throw any light on the question, but the second foal had developed into an animal, now three years old, which was as typical a Tarpan as ever roamed the Russian steppes. The general conclusion was that the Tarpan, once so common in the east of Europe, could not be considered as a true wild species, but was very probably derived from at least three sources:—(1) from a variety of Celtic pony; (2) from a variety resembling the forest horse (*Equus caballus typicus*); (3) from a variety identical with, or closely related to, the wild horse of Central Asia (*E. caballus prjevalskii*).—The horse in Norway: Dr. F. H. A. **Marshall**. The horses in Norway belonged to two distinct types, represented by the pure fjord horse and the Gudbrandsdal horse. The former was probably by origin identical with Prof. Ewart's "Celtic pony," while the latter belonged to the forest or cart-horse type. The fjord horse was now, as formerly, typically light dun in colour. The Gudbrandsdal was formerly of almost the same colour, but it was now generally dark brown or black, owing to an infusion of Danish and other foreign blood. The two types of Icelandic horses were derived respectively from the ancestors of the fjord horse and of the Gudbrandsdal horse.—Elimination in the case of equality of fractions whose numerators and denominators are linear functions of the variables: Dr. Thomas **Muir**. The investigation led with great ease to an interesting identity between a determinant of the $(n+1)$th order the constituents of which were determinants of the nth order and one of the nth order the constituents of which were of the $(n+1)$th order, an identity which would be difficult to establish directly.

PARIS.

Academy of Sciences, November 20.—M. Troost in the chair.—Researches on the insoluble alkaline compounds contained in living plant tissues: M. **Berthelot**.—On the Thalassinidæ collected by the *Blake* in the Gulf of Mexico: E. L. **Bouvier**. This group of crustaceans occupies an important place in the deep-sea collections made by the *Blake* expedition. Several new species are described.—On the attitudes of some Tertiary animals of Patagonia: Albert **Gaudry**.—The evolution of terrestrial relief: A. **de Lapparent**.—On the impossibility of negative waves of shock in gases: P. **Duhem**. Remarks on a paper on the same subject by M. G. Zemplén.—On the grains of Sphenopteris: M. **Grand'Eury**.—On the observation of the total eclipse of the sun of August 30, 1905, at Alcosebre, Spain: G. **Millochau**. A *résumé* of results obtained with the telespectrograph.—Interpolation formulæ for continuous periodic functions: Maurice **Fréchet**.—On the development in continued fractions of the function $(F(h, 1, h', u)$, and the generalisation of the theory of spherical functions: H. **Padé**.—On a theorem of M. Poincaré relating to the motion of a heavy solid: Édouard **Husson**. A new demonstration of this theorem is given.—On the application of the partial liquefaction of air with a view to the complete separation of the air into pure oxygen and nitrogen: Georges **Claude**. Details are given of a system of fractional distillation of liquid air. From 100 parts of air, about 14 parts of pure oxygen are obtained by the process originally described by the author. The improvements in the apparatus now described permit of a practically complete separation of the two gases.—The density of nitric oxide; the atomic weight of nitrogen: P. A. **Guye** and Ch. **Davila**. The nitric oxide used in these experiments was prepared by three methods, the action of mercury upon sulphuric acid containing nitrous fumes, the reduction of nitric acid by ferrous sulphate, and the decomposition of sodium nitrite by sulphuric acid in dilute solution. The gas was dried by sulphuric acid and phosphoric anhydride, solidified in liquid air, and purified by fractional distillation. The mean density found was 1·3402 grams per litre, practically identical with the value recently found by Gray—1·3402. This leads to a value for the atomic weight of nitrogen between the limits 14·006 and 14·010, a confirmation of the number 14·009 found in previous researches.—The action of chloride of silicon on iron: Em. **Vigouroux**. Silicon chloride is decomposed by iron a little below a red heat. No lower chloride of silicon appears to be formed, the silicon set free forming an alloy with the iron containing about 20 per cent. of Si, corresponding to the formation of the well known compound Fe_2Si.—On the preparation of racemic amyl alcohol: P. **Freundler** and E. **Damond**. The alcohol is prepared by the interaction of trioxymethylene with the magnesium compound of secondary butyl bromide, details being given of the precautions necessary to obtain a good yield.—The diffusion of barium and strontium in the sedimentary strata: L. **Collot**.—On the increase in the dry weight of green plants developed in the light, in the absence of carbon dioxide, in a soil to which amides have been added: Jules **Lefèvre**. It has been shown experimentally that the growth of green plants in a soil containing amides, and in the absence of carbon dioxide, is accompanied by a rapid increase in the dry weight. The growth under these conditions is therefore real, and not merely a phenomenon of hydration.—On the structure and evolution of *Rhacodium cellare*: F. **Guéguen**.—On juglone: M. **Brissemoret** and R. **Combes**. Contrary to the usually accepted view, it is shown that juglone exists already formed in all the green organs of the walnut (leaves, stem, nut). The method used for the extraction is given in detail.—Rheotropism in some hydroids and Bugula: Paul

Hallez.—The influence of high altitudes on the general nutrition: H. **Guillemard** and R. **Moog.** The observations were carried out at Paris, at the Grand Mulets (3050 metres), and the summit of Mt. Blanc (4810 metres), the changes in the urine being more specially examined. It was found that the effect of high altitudes on nutrition was to produce a diminution of the oxidation processes, diminution of diuresis, and retention of the fixed elements.—The spleen and the biliary secretion: N. C. **Paulesco.** Experiments on dogs leads to the conclusion that the spleen exercises no apparent influence on the formation of bile.—Researches on the formation of hæmoglobin in the embryo: L. **Hugounenq** and Albert **Morel.**—The aurora borealis of November 15 and the magnetic disturbances of November 12 and 15: Th. **Moureaux.** The appearance of the aurora corresponded to strong magnetic disturbances.—Observations on atmospheric electricity in Grahamsland: J. **Rey.**

DIARY OF SOCIETIES.

FRIDAY, DECEMBER 1.

INSTITUTION OF CIVIL ENGINEERS, at 8.—An Installation for the Bacterial Treatment of Sewage, at Neath: W. L. Jenkins.

GEOLOGISTS' ASSOCIATION, at 8.—*Gazella Daviesii*—A New Antelope from the Norwich Crag of Bramerton: M. A. C. Hinton.—On Sections of the Holocene Alluvium of the Thames at Staines and Wargrave: A. S. Kennard and B. B. Woodward.

MONDAY, DECEMBER 4.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Exploration in the Abai Basin, Abyssinia: H. Weld Blundell.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Notes on Gutta Percha and Balata: Dr. W. A. Caspari.—The Determination of Zinc in Zinc-Aluminium Alloys: Dr. R. Seligman and F. J. Willott.—Distilled Water Supply for "Works' Laboratories: Dr. R. Seligman.—The Estimation of Naphthalene in Coal Gas: C. J. Dickinson-Gair.—Salts of the Alkaloid Cinchonamine: B. F. Howard and F. Perry.

SOCIETY OF ARTS, at 8.—The Measurement of High Frequency Currents and Electric Waves: Prof. J. A. Fleming, F.R.S.

TUESDAY, DECEMBER 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Steam-Turbine: Hon. C. A. Parsons, C.B., F.R.S., and G. G. Stoney.

WEDNESDAY, DECEMBER 6.

GEOLOGICAL SOCIETY, at 8.—The Physical History of the Great Pleistocene Lake of Portugal: Prof. E. Hull, F.R.S.—The Geological Structure of the Sgurr of Eigg: A. Harker, F.R.S.—The Buttermere and Ennerdale Granophyre: R. H. Rastall.

ENTOMOLOGICAL SOCIETY, at 8.—Descriptions of new Genera and Species of African Galerucidæ and Halticidæ: M. Jacoby.

SOCIETY OF ARTS, at 8.—The Manufacture of Sugar from British-grown Beet: Sigmund Stein.

Law.—Note on the Removal of Arsenic from Hydrochloric Acid for Use in the Marsh-Berzelius Method: A. R. Ling and T. Rendle.—Note on Dutch Cheese: C. H. Cribb.—Improved Arrangement of Lenses for Reading Balance Graduations: G. T. Holloway.

THURSDAY, DECEMBER 7.

ROYAL SOCIETY, at 4.30.—The Periodogram and its Optical Analogy; with an Illustration from a Discussion of Observations of Sun spots: Prof. A. Schuster, F.R.S.—(1) On a Property which holds good for all Groupings of a Normal Distribution of Frequency for two Variables, with Applications to the Study of Contingency-tables for the Inheritance of Unmeasured Qualities; (2) On the Influence of Bias and of Personal Equation in Statistics of Ill-defined Qualities: an Experimental Study: G. Udny Yule.—On the Inheritance of Coat-colour in Horses: C. C. Hurst.—A Biometrical Study of Conjugation in Paramæcium: Dr. Raymond Pearl.—On Mathematical Concepts of the Material World: A. N. Whitehead, F.R.S.—The Determination of the Osmotic Pressure of Solutions by the Measurement of their Vapour Pressures: The Earl of Berkeley and E. G. Hartley.—The Vertical Temperature Gradients on the West Coast of Scotland and at Oxshott, Surrey: W. H. Dines, F.R.S.—The Combination of Hydrogen and Oxygen in contact with Hot Surfaces: Dr. W. A. Bone, F.R.S., and R. V. Wheeler.

SOCIETY OF ARTS, at 4.30.—The Partition of Bengal: Sir James A. Bourdillon, K.C.S.I.

CHEMICAL SOCIETY, at 8.30.—The Constitution of Nitrites, Part I., Two Varieties of Silver Nitrite: P. C. Rây and A. C. Ganguli.—The Products of Heating Silver Nitrite: E. Divers.—Ethyl Piperonylacetate: W. H. Perkin, Jun., and R. Robinson.—A Contribution to the Chemistry of Saccharin: F. D. Chattaway.—The Action of Heat on α-Hydrocarboxylic Acids, Part II.: H. R. Le Sueur.—Studies on Optically Active Carbimides, Part II., The Reactions between 1-Menthylcarbimide and Alcohols: R. H. Pickard, W. O. Littlebury, and A. Neville.—The Action of Ultra-violet Light on Moist and Dried Mixtures of Carbon Monoxide and Oxygen: S. Chadwick, J. E. Ramsbottom and D. L. Chapman.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Charing Cross Company's City of London Works: W. H. Patchell.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Concrete Mixers: Dr. J. S. Owens.

LINNEAN SOCIETY, at 8.—On the Ætiology of Leprosy: Dr. Jonathan Hutchinson, F.R.S.—Some Notes on the Life history of *Margaritifera Panesene*: A. W. Allen.—*Exhibition*: Photographs of a Luxuriant Specimen of *Shortia uniflora*, in the Rock-garden of Mr. W. T. Hindmarsh, at Alnwick.

FRIDAY, DECEMBER 8.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY, at 8.

MALACOLOGICAL SOCIETY, at 8.—(1) A Revision of the Species of Cyclostomatidæ and Liotiidæ occurring in the Persian Gulf and North Arabian Sea; (2) Description of Two Species of Marine Shells from Ceylon: J. Cosmo Melvill.—A Pteropod Alias: (*a*) C. Hedley. (*b*) E. R. Sykes.—(1) Descriptions of Four new Species of Marine Shells from Ceylon; (2) Description of a new Species of Physa from N.W. Australia: H. B. Preston.—Notes (1) on the Dates of Publication of J. D. Wilhelm Hartmann's "Erd- und Süsswasser-Gasteropoden," 8vo, St. Gallen, 1840; (2) On Some "Feeding Tracks" of Gastropods; (3) On Cement as a Slug-killer: B. B. Woodward.

CONTENTS.

THURSDAY, DECEMBER 7, 1905.

THE PRINCIPLES OF HEREDITY.

The Principles of Heredity, with Some Applications. By G. A. Reid. Pp. xiii+359. (London: Chapman and Hall, Ltd., 1905.) Price 12*s*. 6*d*. net.

THE publication of this book marks an epoch in the history of the relation between medicine and biology, inasmuch as it is an embodiment of the recognition by medical men that they depend ultimately for a precise knowledge of nature on the professional biologist who may or may not, at the same time, be a medical man.

The book should be welcomed by doctors as containing, in the earlier chapters a straightforward though rather brief account of theories of organic evolution, and by biologists as giving a very full account of the medical aspect of these problems, and by both as an interesting collection, under the title of "The Principles of Heredity," of a mass of information and ideas connected with that phenomenon.

The reader may object to the antithesis between medicine and biology, but will, we hope, withdraw his objection when it is explained that all that is meant by it is the antithesis between applied and pure biology.

The recognition by medical men of the value to them of the information with which the biologist is able to supply them is unquestionably a good thing; yet it is a curious illustration of the fact that a new movement of opinion cannot stand isolated and alone, cannot be without consequences of one kind or another, that one result of the popularity of the *entente* between the doctor and the biologist may prove harmful to biology, and through it perhaps ultimately to medicine.

The danger is that the biologist, pure and simple, the man who works at his subject for the mere joy of investigation and discovery, may cease to exist. So many workers of this type are becoming applied biologists, whether they be sporozoologists devoting themselves to malaria, students of heredity to eugenics, or cytologists to cancer. We do not, of course, complain of the application of biological knowledge; it is obviously fitting and right that as much use should be made of it as possible. But we do complain loudly of the opinion that the application of such knowledge is, or should be, the ultimate goal of him who acquires it. Huxley strongly insisted on the fact that the fruits, useful to mankind, of the tree of natural knowledge fell unsought for and unexpected on the back of the head of some obscure worker under its shade, and never to him who worked there with outstretched palm. Dr. Reid says, p. 331,

"Hitherto the nature of their training has tended to render medical men excessively conservative. Nevertheless they have already assimilated and put to magnificent practical use one of the two great scientific achievements of the age—Pasteur's discovery of the microbic origin of disease. The other great achievement, Darwin's discovery of the adaptation of species to the environment through natural selection, has hardly been assimilated, and certainly put to no practical use as yet. Both these discoveries should have been made by medical men."

The fact that they were not is an illustration of the truth of Huxley's words.

Let it be emphasised again that we do not hold that the gradual desertion of biologists from the ranks of the pure to those of the applied is other than of the greatest service to mankind. But if this desertion means that the opinion that the natural goal of the young biologist is to obtain a position in applied biology will grow, it is a bad thing for science. So that even if it is only on the ground that the utilitarianism which may lead to the extinction of the pure biologist is a bad one, it is to be deplored. If we are going to be utilitarians let us at least be good ones, and let us recognise the demonstrable fact that the only way in which the knowledge and consequent control of nature can be acquired is by encouraging the existence of the type of man who works at his subject for its own sake. Let us have less of the talk about the profound significance of such and such a branch of investigation to the sociologist and the statesman and more of the frame of mind which finds expression in Bateson's words:—"We are asked sometimes, Is this new knowledge any use? That is a question with which we, here, have fortunately no direct concern. Our business in life is to find things out, and we do not look beyond."

With regard to this utilitarianism Dr. Reid appears to us to steer the right course in his book, except, perhaps, that he sails rather too near it when, pointing out that a classical education is inefficient and does not make us like the Greeks and Romans, he says,

"the true modern representatives of the great Pagans are not to be found in college halls or country parsonages, but in thinkers and workers like Darwin, Huxley, Kelvin, Cecil Rhodes, the strenuous men who rule Egypt and India. . . ."

Surely the patient inquiring spirit which prompts a man to devote himself to classics is the same as that in the heart of the true man of science. One of the greatest steps forward in the study of heredity itself was made by a monk.

Dr. Reid's book is tolerably free from that looseness in the use of scientific terms which is common enough in purely scientific works, but which is simply rampant in books on popular science.

The reader who wishes to familiarise himself with the subject of heredity should be very careful to distinguish between the two meanings of the term regression, the one which is a purely biological phenomenon and the other which is a purely statistical conception. With regard to the use of that much-abused word "law," our author makes a statement that at first sight seems to show that he has not thought very seriously about the meaning of that

word. But we do not believe our author wishes to be taken seriously here:—

"Even if we postulate a Deity as the Originator of all things, yet the whole history of science, which is that of civilisation, proves that it is more profitable to seek the *explanation of natural phenomena in natural laws* (*His laws*) *than in infractions of them*—in miracles." (The italics are mine.)

We have one fault to find; in a work on the principles of heredity one would have expected a fuller discussion than is actually given of biometric and Mendelian methods of dealing with that phenomenon: medical men reading the book will get a very meagre idea of the nature of the investigation being carried on and of the definite results already achieved by these two sets of workers.

Dr. Reid does good service in dealing a blow at that teleology which is the curse of biological science by exposing the falsity of the old idea that the "object" of bi-parental reproduction is to ensure a sufficient degree of variability in each generation for natural selection to operate upon. He cites as evidence for this Dr. Warren's work on *Daphnia magna*; but does not refer to a more recent and more complete demonstration of the same truth by the same author in the case of Aphis, to be found in *Biometrika*, vol. i., p. 129.

These, however, are trifles, and do not detract from the value of the book as a whole. A. D. D.

MATHEMATICAL LECTURES FOR AMERICAN MATHEMATICIANS.

The Boston Colloquium. Lectures on Mathematics. By Edward Burr Van Vleck, Henry Seely White, and Frederick Shenstone Woods. Pp. xii+188. (New York: The Macmillan Company, 1905.) Price 2 dollars net.

Lectures on the Calculus of Variations. By Dr. Oskar Bolza. Pp. xvi+272. (Chicago: The University Press, 1904.) Price 4 dollars net.

AMONG the many ways in which the American Mathematical Society has endeavoured to popularise and develop the study of higher mathematics, not the least remarkable and useful is the practice of holding "colloquia" in connection with the summer meetings at intervals of two or three years. It had been felt that the mere reading of a long string of disconnected papers does not produce much lasting impression on the minds of the audience. On the other hand, even a short course of university lectures will often adequately cover a wide range of mathematical study. The society therefore decided in 1896 to arrange for courses of three to six two-hour lectures, each dealing with a substantial part of mathematics. Four such colloquia have been held, at Buffalo in 1896, at Cambridge in 1898, at Ithaca in 1901, and at Boston in 1903. At each of the first three two courses of lectures were given, and Prof. Oskar Bolza's course on "The Simplest Type of Problems in the Calculus of Variations," given at the Ithaca colloquium of 1901, forms the basis of one of the two volumes before us. The chapters nearly follow the historic order laid down in the introduction, which is also in close conformity with a logical sequence of treatment. The study of the first and second variations of an integral naturally leads to Weierstrass's examination of the conditions for a minimum and the distinction between a "strong" and a "weak" minimum, a terminology introduced by Kneser. The next steps are represented by Weierstrass's theory of parameter representation, Kneser's general theory based on the properties of geodesics, and Hilbert's existence-theorem. For Weierstrass's work (much of which is contained in unpublished courses of lectures) the author has had recourse to his own notes of a course (by Weierstrass) which he attended in 1879, as well as to several other sets of lecture notes, including one on Prof. Schwarz's lectures at Berlin on the same subject.

At the next colloquium, held at Boston in September, 1903, three courses of lectures were given. The year marked the fiftieth anniversary of the appointment of Prof. John Monroe Van Vleck to the chair of mathematics at Wesleyan University, and it was fitting to the occasion that all the lecturers were Van Vleck's pupils, one of them being his son. Prof. Henry S. White, of North-Western University, is responsible for the course of three lectures on "Linear Systems of Curves on Algebraic Surfaces," Prof. Frederick S. Woods, of the Massachusetts Institute of Technology, for three lectures on "Forms of Non-Euclidian Space," and Prof. Edward B. Van Vleck, of Wesleyan University, for six lectures on "Selected Topics in the Theory of Divergent Series and Continued Fractions." A bibliography of literature on continued fractions extending over twenty pages concludes the last named discourse.

Long formulæ involving x and y are like little children—they ought to be "seen and not heard." The success of these colloquia when originally delivered must have been in some considerable measure due to the extent to which the authors have succeeded in dealing with ideas and their symbolical representations without giving tedious demonstrations *in extenso*.

INDUSTRIAL REFRIGERATION.

Modern Refrigerating Machinery, its Construction, Methods of Working, and Industrial Applications. By Prof. H. Lorenz. *American Practice in Refrigeration.* By H. M. Haven and F. W. Dean. Pp. x+396. (New York: Wiley and Sons; London: Chapman and Hall, Ltd., 1905.) Price 17s. net.

IT is to be regretted that no treatise exists on this subject which contains an exhaustive investigation of the thermodynamical problems involved, and of the physical properties of the various gases used as media, with special reference to their practical application to refrigerating machinery. In works on thermodynamics, the matter is treated in general terms. The physical constants are found in scattered

tables, and even with such a well-known gas as carbon dioxide they have not been completely determined. It has become more and more necessary for the engineer or manufacturer to be familiar with the scientific researches and theoretical considerations which lie at the base of his industry, and Germany has come to be looked upon as the leader in fundamental work of this sort, but the "Neuere Kühlmaschinen" of Prof. Lorenz makes no pretence to be of this comprehensive character. While refrigerating machinery is sufficiently simple, the principles on which it is based are not so easy of comprehension to the working engineers and business men who use it industrially. As a handbook for men of this class and as a *résumé* of the subject, this manual has long been known in Germany and on the Continent. Various editions have been published as a volume of the "Technische Handbibliothek," and the present translation under the title of "Modern Refrigerating Machinery" is from the edition of 1901.

No space is taken up by a historical introduction, but after some pages of an elementary character on the principles of heat there follows a chapter on "Methods of Cold Production," which gives a well arranged and concise description of the manner in which refrigeration is produced by different methods and of the energy required. The chapter on compressors treats chiefly of the important details of the machines, and wisely does not touch upon matters which belong more properly to generic and not to special machine design, and has some instructive indicator diagrams. The chapters which follow deal with condensers and evaporators, the cooling of liquids and air, and the manufacture of ice. They describe clearly the chief features of the matter under discussion, and do not enter upon general descriptions from which it is difficult to decipher the essential points. The pages devoted to very low temperatures, written four years ago, have now become merely of historical interest. The final chapter, on the performance of refrigerating machines, or, as the translator calls it, "The Yield of Cooling Machines," contains the only higher mathematics in the book, which contrast rather strangely with some of the simple definitions at the beginning. The translation is poor. The German original is closely followed. Such sentences as "tightness towards gases requires, besides faultless material, as small a number as possible of tubulures and stuffing boxes" are not very clear to an English mechanic, nor does the constant use of italics for the more important words add to the attractiveness of the pages. The illustrations are numerous and excellent, and the cuts are superior to those in the German edition.

In the same volume, though the pages are numbered consecutively, is a separate work on "American Practice in Refrigeration." It contains some admirable illustrations and useful data in regard to the construction of cold storage rooms, but it is not quite apparent what purpose the American authors could have in view in reprinting tables from such well-known books as those of Siebel and Wallis-Tayler.

C. H. B.

OUR BOOK SHELF.

The Geography of New Zealand. By P. Marshall. Pp. x+401. (Christchurch, N.Z., and London: Whitcombe and Tombs, Ltd., n.d.)

THE author claims to have written "according to the spirit of the New Geography," to give due consideration to the influence that the relief of the land has upon the circulation of the atmosphere, the climate, the distribution of flora and fauna, and the settlement of population; he explains that the latter is influenced considerably by the distribution of mineral deposits, while the nature of the industries affects the commerce of the country and shapes its political institutions.

The work is for this purpose divided into three parts, under the headings (1) historical, (2) physical, (3) political and commercial. There is a valuable introduction by Prof. Gregory, and an important chapter on geysers by the same writer, in which, however, he erroneously alludes to Strokur as being still an active geyser, whereas it ceased to erupt in 1895. The chapter on earthquakes by Mr. G. Hogben deserves special mention; the several kinds of earth movements and their registration by the seismograph are described. Of special interest to all lovers of Ao te Roa the unscientific reader as well as the geographical student—are the chapter on the Maoris, by Mr. A. Hamilton, and the descriptions of various unique natural beauties.

At times the style is very explanatory and the matter original. Occasionally the author's meaning is somewhat vague, as when he writes:—"the high mountainous land here reaches the sea, and is in fact truncated by it." But on the whole the information given is accurate and concise, and the arrangement throughout careful.

As stated in the preface, the book is not merely the result of the author's and his contributors' personal observation, but is a collection of facts and figures from the previous writings of acknowledged authorities on the islands of which it treats. The letterpress is profusely illustrated with maps, reproductions of photographs, sketches, and old prints. These are all interesting, and many of the sketch-maps serve well to illustrate the text.

M. G. B.

Wild Wings; Adventures of a Camera-Hunter among the Larger Wild Birds of North America on Sea and Land. By H. K. Job. Pp. xxv+341; illustrated. (London: A. Constable and Co., Ltd.; Boston and New York: Houghton, Mifflin and Co., 1905.) Price 10*s.* 6*d.* net.

DESPITE its somewhat pedantic title, this book is much above the average of works of the same general nature, and deserves a wide circulation, if only on account of the earnest plea made by its author that the camera may, at least to some extent, be substituted for the shot-gun in our intercourse with birds. In this laudable endeavour he is supported by the President of the United States, who, after stating that wild-game shooting, under proper restrictions and regulations, must be considered legitimate so long as we breed domesticated animals for slaughter, observes that "there is altogether too much shooting, and if we can only get the camera in place of the gun and have the sportsman sunk somewhat in the naturalist and lover of wild things, the next generation will see an immense change for the better in the life of our woods and waters."

The special feature of Mr. Job's book is undoubtedly formed by the illustrations, all of which, we are told, are reproductions—and very excellent ones—of photo-

graphs taken by the author himself. In a country of the size and extent of America, with climates ranging from the arctic to the tropical, and with large tracts of more or less untrodden wastes, the bird-lover and photographer has, of course, vastly greater opportunities (especially among the larger species, to which the author has confined his attention) than his brother in our own islands, and it must be confessed that these opportunities have not been neglected, for a more delightful book, both as regards text and illustrations, it would be difficult to produce.

The breeding colonies of brown pelicans of New England must form a really marvellous sight. On the occasion of the first visit of the author and his party, the boat was run ashore without alarming the birds. "Then," writes the narrator, "we stood up and shouted, but hardly a bird rose. There they sat upon their nests, hundreds and thousands of them, many within forty or fifty feet, solemnly gazing at us. It was not until we sprang out upon the shore that there was any considerable flight, and even then we noticed that it occurred only within a radius of fifty or sixty feet, the rest of the colony remaining on their nests apparently in perfect unconcern." Time after time the colony has been raided by feather and egg hunters, but it is satisfactory to learn that Pelican Island has recently been made by President Roosevelt a Government reserve for wild birds.

Not less interesting is the author's account of the colonies of white ibises and Louisiana herons in the Cape Sable wilderness, this being followed by a fascinating description, with equally fascinating photographs, of the colonies of sooty terns and noddies on "Lonely Bird Key," in the Dry Tortugas group, far out in the Gulf of Mexico. But if we were to cite even a tenth of the passages to which we should like to refer, editorial limits would be far exceeded, and in bringing this brief notice of an admirable bird-book to a close we cannot do better than advise our readers to get copies for themselves.

Instruction in Photography. By Sir W. de W. Abney. Eleventh edition, revised. Pp. 676. (London: Iliffe and Sons, Ltd., 1905.) Price 7*s.* 6*d.* net.

THIS work, which for many years has held the premier position among English text-books of photography, is to a peculiar extent the record of the author's own experiments and investigations, and in the new edition much new matter on the subject of colour photography has been added, the product of the attention which Sir W. de W. Abney has devoted to that branch of photography for some years. In other sections of the book it may be noted that the descriptions of lenses are brought up to date, while the chapter on sensitometry includes a description of Mr. Chapman Jones's plate tester. An entirely new chapter has been added to the book entitled "The Failure of a Photographic Law," and including the well known experiments made by the author upon the effect of intermittent exposures and upon the failure of the reciprocity law. Here also will be found an interesting discussion of the effect of temperature upon the sensitiveness of plates, while the last part of the chapter is devoted to an account of the author's researches upon the effect of different monochromatic lights upon a plate. The book has been entirely reset, larger type being employed throughout and the printing generally improved. No alteration has been made in the theoretical views set forth, and the silver sub-bromide theory of the latent image is adopted in its entirety. C. E. K. M.

La Bobine d'Induction. By H. Armagnat. Pp. 228. (Paris: Gauthier-Villars, 1905.) Price 5 francs.

IN this book a very interesting account is given of the induction coil in its theoretical and practical aspects. The electromagnetic problems involved are clearly stated, and the various factors which stand in the way of a complete mathematical theory are considered in some detail. The effects of sparking at the interruptor, the parts played by the iron core, by the secondary capacity, &c., are carefully examined and methods of experimental investigation are illustrated. The differences between mechanical and electrolytic interruptors are discussed, and the more purely theoretical part of the book concludes with a chapter on the power and output of a coil and of the factors upon which these depend. The methods of measuring the electromagnetic constants of a coil are indicated, as are the most common sources of breakdown, how they may be detected, and how in some cases remedied.

In the description of the practical construction of coils which follows, the different methods of winding, insulation, &c., are described in detail, and the relative dimensions of the various parts of coils of standard makes are given. The particular features of different types of interruptors, mechanical and electrolytic, upon which efficient working depends are stated clearly (although the action of the commonest mechanical interruptor is not quite so simple as it is made to appear, and might perhaps have been described in greater detail in a book of this kind).

The principles of the action of several special forms, such as Tesla's, of induction apparatus used in practice are given in outline, and a final chapter is devoted to a description of the various uses of induction coils. The range of this chapter is perhaps indicated when it is said that it includes the discussion of such questions as the ignition apparatus of explosion-engines and the production of ozone.

A very useful bibliography, in which the references are in most cases accompanied by short abstracts, completes an excellent book.

Handbook of Metallurgy. By Prof. Carl Schnabel. Translated by Prof. Henry Louis. Second Edition. Vol. i. Copper—Lead—Silver—Gold. Pp. xx + 1123. (London: Macmillan and Co., Ltd., 1905.) Price 25*s.* net.

THIS volume is a translation of the second German edition which appeared in 1902. Prof. Schnabel has found it necessary to increase the length of the book considerably, the translation being 214 pages longer than that of the first edition. A number of new furnaces and other appliances are described, and in particular the account of the extraction of copper by electro-metallurgical methods has undergone great expansion. The older metallurgical methods are purposely dwelt on by the author, who gives as his reason that a knowledge of the development of metallurgy stimulates inventive genius. It is equally certain that the inclusion of the descriptions of out-of-date methods helps to make books bulky.

The merits and defects of the book remain much the same as in the first edition. It contains a mass of detailed information as to the dimensions of appliances in use at particular works, the analyses of products, and the like, but the discussion of the principles underlying the practice is generally less thorough. This is as much as to say that the book is "practical." Prof. Louis is to be congratulated on the translation, which makes a valuable work available to British students.

The Second Law of Thermodynamics.

THE point which Mr. Browne (p. 102) raises is covered by Voigt ("Thermodynamik," vol. ii., § 69, pp. 209 *et seq.*). Ordinary diffusion of two gases at equal pressure and temperature is an irreversible process involving loss of available energy, but when the diffusion takes place through porous membranes this available energy can be utilised in a greater or less degree in the form of work, and this is the case in Mr. Browne's experiment. By introducing the conception of "semi-permeable partitions," Voigt obtains a reversible method of mixing or separating gases. In this case the partial pressure of the mixture is equal to the sum of the partial pressures of the components. In ordinary diffusion the volume of the mixture is equal to the sum of the volumes of the components. The work of expansion from the former to the latter final state can be utilised if a reversible transformation is employed. It is lost in the case of ordinary diffusion. An equal amount of work must, however, be supplied from without to separate the gases. The results are fully in accordance with the second law. G. H. BRYAN.

MR. M. A. BROWNE's letter (p. 102) raises an interesting and difficult question which at some period of his career must be faced by every student attempting to grasp for himself the significance of the second law of thermodynamics. As I, with difficulty and without much help from the text-books, extricated myself from a similar dilemma, perhaps the steps in the train of reasoning which helped me may interest others.

There is no need to take the complicated case chosen by Mr. Browne of the diffusion of hydrogen and nitrogen through a palladium septum. A precisely analogous difficulty exists in the simpler case of an ordinary cylinder of compressed gas doing external work on expansion either at the expense of its own heat or of the heat of uniform temperature of its environment. The gas expands and does an amount of external work W, while the equivalent H units of heat flow into the gas from the surroundings, so that the result of the process is that H units of heat at the uniform temperature of the surroundings have been quantitatively converted into external work. This is, no doubt, contrary to many of the earlier statements of the second law.

The test, of course, is to compress back the gas into the cylinder, when at least W units of work have to be converted back into heat during the process. Moreover, this must be done whether or not the gas did work on expansion. Although a gas expands freely into a vacuum, doing no work, and, as Joule has shown, experiencing no appreciable change of total energy in the process, to get it back again into the cylinder, at least W units of work must be converted into heat. I know of no better way of introducing thermodynamical considerations to the chemical student than by commencing with the concrete case of a gas cylinder. The extension of the same considerations to all processes naturally occurring, the flow of heat from a hot to a cold body, the diffusion of gases through septa, the change of one allotropic form of element into another, all follow as illustrations of the "majestic" and "universal" law that that mysterious something which is not energy, but an abstraction of energy—its availability for work—tends always to a minimum, or, as others have it, the entropy increases. The student passes his examination, no doubt, but if he is a philosopher he may prefer to meet his difficulties singly, and not have them "concentrated in a phrase." It is possible that he may like to think sometimes of a gas as expanding, because it is its nature to. The reason is easily understood on mechanical or kinetic considerations. But the attempt to replace these considerations by the two *ex cathedra* statements—(1) the entropy of a gas increases during increase of volume, (2) the entropy of the universe tends to increase—and to deduce from them the direction of natural tendency in the case of a gas changing in volume, seems to the writer to involve the thermodynamical equivalent of the fallacy of "putting the cart before the horse." We cannot escape mechanical and molecular considerations.

The University, Glasgow. F. SODDY.

Atomic Disintegration and the Distribution of the Elements.

WITH reference to the association of uranium and radium, would you permit me to put on record a point that must have occurred to many, though possibly not to some, of those who are speculating so brilliantly about uranium and its disintegration products. I refer to the extraordinary conjunction in nature between silver and lead. This conjunction is so frequent that it can hardly be casual. A lead mine is a silver mine and a silver mine a lead mine all the world over, and yet the chemical attraction between silver and lead is slight, and the two metals are not sufficiently common to concur by chance. It is to be noted also that the concurrence, if the word may be used in this sense, is usually of the order of ounces for silver and tons for lead, and that the atomic weight of lead is 207 and of silver 108. Hence there appears to be some ground for the suspicion that silver is a disintegration product of lead. Lead also happens to present special facilities for experiment to test this surmise. It is cheap, and it is a comparatively inexpensive matter to free ten tons of lead from all traces of silver by the usual crystallising process, and then put it aside for ten years and test again for silver by the same process.

There are several other curious groupings of elements in nature that seem to be worthy of consideration from the transmutation point of view. One of these is the frequent concurrence of copper and gold. In the Great Cobar copper mine in New South Wales the gold occurs in the ratio of about four ounces to the ton of copper. Such conjunctions as gold and quartz are, of course, easily explained by chemistry and coincidence, and chemical forces also sufficiently explain the concurrence of sulphur with silver and lead, but the giant deposits of silver, lead, and zinc, with smaller quantities of copper and still smaller quantities of gold at Broken Hill, in Australia, to say nothing of similar vast deposits in many other countries, can hardly be due entirely to chemical and casual forces. Anyone interested in the subject will find much statistical and other information in the annual report of the Broken Hill Proprietary Company. This document affords considerable food for reflection, and a visit to the mine itself is absolutely awe-inspiring. Walking through galleries of glittering grey crystals of silver, lead, and zinc sulphide—solid ore—for 300 feet *across* the lode, which is a mile or more in length and of unknown depth, is one of the experiences of a lifetime. DONALD MURRAY.

3 Lombard Court, London, E.C., November 30.

Zoology at the British Association.

IN your account, under the above heading, of the proceedings of Section D of the British Association at Johannesburg, you state (p. 40) that in my paper on Cephalodiscus I "gave a preliminary account of the new species discovered in African seas by Dr. Gilchrist."

I shall be obliged if you will allow me to say that my communication to Section D consisted of an abstract of the results which were published, last July, in my report on "The Pterobranchia of the *Siboga* Expedition," and that it did not include any account of Dr. Gilchrist's specimens of Cephalodiscus. S. F. HARMER.

King's College, Cambridge, November 14.

[Our contributor was unfortunately engaged in the committee room during Dr. Harmer's introductory remarks, and this led to the misunderstanding to which Dr. Harmer directs attention.—EDITOR.]

THE THOROUGHBRED HORSE.[1]

THE re-discovery of the so-called *Equus przewalskii*, or Mongolian wild pony, has during the last few years awakened renewed interest in the puzzling question of the origin and ancestry of our domesticated breeds of horses and their relations to their wild or semi-wild representatives, and workers on both sides of the Atlantic have been doing their best, with results more or less satisfactory (at least to themselves), to solve the problem. The subject, like an apparently impregnable fortress, has been attacked from several sides at once, in the hope that if one plan fails another may succeed; and while one worker has endeavoured to solve the mystery by the study of apparently vestigial structures, a second relies on cross-breeding, while a third believes that external characteristics are alone sufficient to decide the question. Prof. Ridgeway, on the other hand, has primarily attacked the problem from the point of view of the historian and the archæologist, and it must be acknowledged that naturalists owe him a large debt of gratitude for bringing into prominence lines of evidence with which, from the very nature of the case, they are unfamiliar. Apparently, however, the author soon discovered that salvation was not to be found from archæological investigations alone, and that it was essential for him to enter in some detail into the natural history of *Equus caballus* and its allies. To one who has thus been compelled by force of circumstances to enter on paths of study other than his own, tender treatment should be accorded by the critic, and especially should this be so in the present instance, when the author has called to his assistance at least two naturalists who have specially studied the Equidæ.

FIG. 1.—Norwegian ponies, as examples of the typical dun type of the horse. From Ridgeway's "The Thoroughbred Horse."

As regards the two introductory chapters on the horse family in general, a very large proportion has little or no bearing on the subject, and might advantageously have been omitted. As it stands, it is to a great extent inaccurate and misleading. If, for instance, the list of existing Equidæ on p. 12 be compared with the descriptions of species and races later on, numerous discrepancies will be found. As an example we may refer to the mention of the chigetai, or dzeggetai (*Equus hemionus*), and of the kiang (*E. hemionus kiang*) on pp. 44 and 45, and the complete omission of the former on p. 12, where the latter is quoted as *E. kiang*. The difference between species and subspecies is, however, a great stumbling block to the author, as may be inferred from p. 61, where it is stated that "certain zebras have been made into subspecies by some, though there is no evidence that they are more than local races," and we are left in pleasing uncertainty whether the wild Mongolian pony is a species by itself or a race of *Equus caballus*. In connection with this part of the subject, the omission of any reference to the present writer's latest paper (1904) on wild asses, when his earlier ones are quoted, is noticeable, as is also the statement (p. 143) that he has sought to establish a relation between the ponies of Java and Sulu and *E. sivalensis*. Perhaps too much is also made of the expression "an Indian domesticated horse" in reference to a certain skull (pp. 159 and 470) in the British Museum, which probably belonged to an imported animal. Strong exception must be taken to certain statements, even if they be quotations, connected with fossil Equidæ. It may or may not, for instance, be admitted that the horses of Asia and Europe have an American ancestry; but to state (p. 10) that *Equus stenonis*, the earliest European fossil horse, was one of the earlier immigrants, and that while this species "was extending its range into Europe and Africa, two others, *E. sivalensis* and *E. namadicus*, were finding their way into India," is neither more nor less than nonsense, more especially since the Indian *E. sivalensis* is at least as old, if not older than any known American true horse!

It is time, however, to take into consideration the author's views as to the chief existing types of horses, which appear to be as follows:—First of all we have the "typical horse," that is to say, *Equus caballus typicus*, which we presume must be taken to be the ordinary Scandinavian pony (Fig. 1), although the author does not commit himself upon this point; secondly, the Celtic pony (*E. c. celticus*) of Iceland, the Hebrides, and other parts of north-western Europe; thirdly, the tarpan and Mongolian wild pony, which we may agree to call provisionally *E. c. przewalskii*; and fourthly, the Barb, Arab, and thoroughbred stock, for which the author proposes the name *E. c. libycus*. All the first three appear to be closely allied, and are typically small animals with large heads, short manes, and tails often imperfectly haired at the base, while their general colour is dun with black points. In temper they appear to be intractable, and when first domesticated they seem to have been broken to harness instead of for riding, and to have been controlled with the bit. The Norwegian pony is believed to have considerable intermixture of

[1] "The Origin and Influence of the Thoroughbred Horse." By W. Ridgeway. Cambridge Biological Series. Pp. xvi+535; illustrated. (Cambridge: The University Press, 1905.) Price 12s. 6d. net.

southern blood, and if we allow for this it may be asked whether there is sufficient justification for separating the "Celtic pony" as a distinct race, and whether both do not consequently come under the designation of *E. caballus typicus.* If he be right in identifying the original unaltered tarpan with the Mongolian wild pony (*przewalskii*), the author has done good service, as he certainly has in pointing out that the mouse-colour of the tarpan in the Moscow Museum is a sign of hybridism. Whether *przewalskii* might not also be included under the name of *E. c. typicus* is another question that may be left open.

Turning to the author's fourth type—the Barb, Arab, and thoroughbred—we find this standing out in marked contrast to all the above, so that in any case we have two main groups of domesticated horses. The Barb type, as it may be called for brevity, is a larger horse than the dun northern type, with a more delicate, although long, head, prominent nostrils, curiously sinuous profile, full and profuse mane and tail, a colour which appears to be typically bay, relieved frequently by a white star on the forehead and one or more white "stockings." The occurrence of a depression in front of the eye-socket (whether a remnant of the ancestral face-gland, or, as some suppose, a point for muscular attachment is immaterial) in the skull is admitted as a characteristic of this type. From their large size these horses were from the first used for riding, while their gentle disposition led to their being dominated by a nose-band instead of a bit. All the dark-coloured horses of Europe, notably the Shire horse, are believed to have a more or less strong infusion of Barb or Arab blood, which is, however, most predominant in the thoroughbred.

In thus dividing domesticated horses into two main types, the northern dun and the larger southern bay, Prof. Ridgeway will, we think, command the consent of most naturalists. Whether, however, he is right in regarding the full mane and tail of the Barb type as an original feature and not one largely due to domestication may be an open question. Doubt may be also legitimately entertained as to whether he is justified in making North Africa the birthplace of the bay type. In the first place, there arises a suspicion that he has been biased by a former theory (now happily abandoned) that the Barb type is the descendant of the Somali zebra (*Equus grevyi*). Putting, however, this aside, it may be pointed out that the author does not appear to give sufficient weight to the fact that true wild horses are utterly unknown in Ethiopian Africa, and that northern Africa is but a small outlying part of the Holarctic region, the fauna of which is to a great extent identical with that of southern Europe and western Asia. On these grounds, although we may admit that the true Barb was the earliest representative of the bay type to be domesticated, it seems extremely improbable that the ancestral, and now extinct, form of this race was confined to North Africa, while it is much more likely that it ranged over a large extent of south-western Asia in prehistoric times.

To follow the author in his extremely interesting survey of the spread and modification of the domesticated horse during historic times is unfortunately quite impossible within the limits of our available space, and we can only say that it will repay careful reading. The early existence of the Barb type is indicated by a figure of a Libyan woman riding one of these horses, taken from a vase dating between 664 B.C. and 570 B.C.

In conclusion, the present reviewer, who has been so largely quoted (and by no means in an altogether friendly spirit) throughout the work, may perhaps be permitted a few lines in which to explain his own views on certain points. In the first place, he is affirmed to have definitely assigned India as the birthplace of the bay or Barb type; but reference to the original article (*Knowledge and Scientific News*, August, 1904, p. 174) will show that he merely suggested the derivation of the "thoroughbred and eastern breeds generally . . . from an extinct Indian species, *E. sivalensis.*" It is true that the expression "eastern breeds generally" is somewhat too extensive, but it was meant to apply primarily to Turks and Arabs; while as to *E. sivalensis*, the writer would be the last to suggest that its range was limited to India, and that it might not have had a wide distribution in Asia. In assigning the origin of the Barb type to this or an allied fossil species rather than to the European *E. stenonis*, which likewise presents a pre-orbital depression in the skull, the reviewer was influenced by the fact that the latter is definitely known to have been succeeded in the prehistoric and Pleistocene deposits of north-west Europe by horses which lack that feature. Moreover, if, as Prof. Ridgeway urges, the northern dun and the southern and eastern bay types are essentially distinct, what is more likely than that they should have been respectively derived from Pliocene types of which one is northern and the other eastern and possibly southern? As regards the main thesis—the existence of the two aforesaid main distinct types of domesticated horses—the reviewer is in perfect accord with the author of the work before him. R. L.

SIR J. S. BURDON-SANDERSON, BART., F.R.S.

On Thursday, November 23, in his seventy-seventh year, this distinguished man passed quietly to his rest after a protracted illness of some months. His death removes from the University of Oxford one of its greatest personalities, whilst biological science, especially those branches immediately associated with medicine—physiology and pathology—has suffered an irreparable loss. The remarkable tribute contained in the *British Medical Journal* issued on December 2 shows the extent to which those who are now working at these subjects honoured and reverenced him as their master.

He was born at Jesmond, Northumberland, in December, 1828, being connected on both his father's and his mother's side with men of great distinction; the details of his ancestry are cited in Mr. Francis Galton's hereditary notes as one instance of those family histories which show extraordinary mental capacity or remarkable achievement distributed along the ancestral line. He was never at a public school, but was educated at home in that border county which he always loved, and throughout his life he manifested a special delight in sunlight, stretches of wild moor, mountain streams, rocks, heather, wild flowers, and wild birds. His powers of observation and the interest with which he regarded all natural objects were such that he might have become a great naturalist, but his bent was evidently towards medicine, and his parents, relinquishing their own bias for the legal profession, sent him to Edinburgh for a course of medical training. Goodsir and Hughes Bennett were then the professors of anatomy and physiology, and the latter seems to have exercised great influence on the future physiologist, turning his thoughts to cells and their living processes.

He soon showed some of those characteristics which stamp indelibly the scientific work of his life. Thus,

an entry in the minutes of the students' scientific meetings (Royal Medical Society) of 1850 states that a dissertation was read by John Scott Sanderson, of Newcastle, on vegetable irritability, and his first publication in the *Edinburgh Monthly Journal of Medicine,* 1851, was a criticism of the views held at the time as to the metamorphosis of the coloured blood corpuscles, founded on numerous experiments and observations made by himself. After his graduation in medicine he left Edinburgh and went in 1851 to Paris in order to study chemical methods under Wurtz. Associated with him were several Edinburgh student friends, including Marcet and Pavy; he was soon attracted by the fame of Claude Bernard, whose demonstrations he attended, and by whom he was introduced to Magendie. On his return to England in 1853 Burdon-Sanderson married Miss Herschell (whose brother subsequently became Lord Chancellor), and set up in London as a practising physician, being also attached to St. Mary's Hospital as medical registrar. His wide knowledge and great capacity were immediately recognised, and he was made lecturer in botany and afterwards in medical jurisprudence at the medical school of this hospital.

An opportunity for the display of his powers on a larger scale came in 1856, when he was appointed Medical Officer of Health for Paddington. This office he retained for eleven years, during the last seven of which he held, in addition, the responsible position of Inspector in the Medical Department of the Privy Council, where he became closely associated with one who became his great friend, the late Sir John Simon.

From 1870 his work became more and more identified with experimental investigation along physiological lines, his aim being the more exact study of the reactions of the body tissues in health and in disease. Pathological inquiries were, in his judgment, to be conducted in the spirit, and by the experimental methods, which obtained abroad in connection with physiology, and which he had followed for two years under Claude Bernard. It is the practical application of this physiological view which gives his pathological work such transcendent importance, for in the 'seventies he was the only English pathologist who dealt with the subject in a way which is in accordance with modern methods. A most important outcome of this endeavour to investigate disease by the use of experimental and strictly scientific methods was the bringing over of Dr. Klein to this country.

As assistant professor to Dr. Sharpey in University College, London, from 1870 to 1874, and still more as full Jodrell professor of physiology from 1874 to 1882, he exercised a profound influence upon the advance of medical science. One important aspect of this influence is the revolution which has been effected in the methods of teaching physiology; this was inaugurated by his organisation of class work for practical physiological chemistry and for carrying out simple experiments upon excitable tissues, muscle, nerve, &c. Such practical work, now a conspicuous feature of all academic physiological teaching, was initiated by Burdon-Sanderson, who insisted on its importance, not merely for its obvious educational utility in implanting a knowledge of fact and method, but still more for its value as a means of cultivating powers of observation and inference.

In 1882 he acceded to an urgent request that he should come to Oxford as the first Waynflete professor of physiology. He decided on this course because he believed that it was for the highest interests of medical education, the medical profession, and the public, that the University of Oxford should regain the great position which she once held in regard to medicine. As professor of physiology for twelve years, and then as Regius professor of medicine for nine years, he laboured consistently for this end, and, as his life drew to its close, he had the supreme satisfaction of realising that the end had been practically attained. Departments of human anatomy, physiology, and pathology, efficiently equipped and under competent professors, form the material witness of this achievement, but the students who have passed through the scientific medical course at Oxford furnish still more cogent evidence of the great resuscitation which he has brought about; for Oxford this is his enduring monument.

Sir John Burdon-Sanderson was so distinguished as a scientific man, and conducted important investigations in so many branches of medical science, that it is possible in the space of this memoir to make only a brief reference to the most conspicuous of his researches. As regards the whole of his physiological and pathological work, extending over a period of nearly fifty years, certain features stand out prominently. His adoption throughout of experiment as the only fruitful method; his belief that "no real advance could be made until it became possible to investigate the phenomena by methods approaching more or less closely to those of the physicist in exactitude"; his constant anxiety that attention should be focused upon the processes which are observed in living tissues, whether normally present in health or modified in disease; and finally his conviction that all such processes, observed either in isolated tissues or in particular organs of the body, are to be regarded as exhibited because they are inexorably linked with the interests of the whole organism of which the particular structures form a part—natural selection in its widest sense.

In practical medicine his desire for exactitude led him to invent the stethograph for obtaining mensurable records of the respiratory movements of man, and to modify Marey's sphygmograph in order to obtain such records of the arterial blood pressure.

In pathology he employed similar exact methods for the investigation of the inflammatory process and of infective diseases, particularly tuberculosis, pyæmia, and septicæmia. His reports to the Privy Council, and his other publications on these subjects, reveal conceptions as to the character of the processes involved in disease, and of the nature of the response of the normal tissues to infective introduction, which are still far ahead of the general knowledge of the present day, and are viewed from the standpoint, in all essentials, of the modern pathologist. A remarkable instance of this is furnished by his early work on immunity, a subject which, in its recent development, has acquired an importance for the health of the community which it would be difficult to overestimate. Thus, three years before Pasteur published his celebrated work on the subject, Burdon-Sanderson showed that anthrax virus could be attenuated by its transmission through the bodies of rodents, and suggested that it might be possible, by using the attenuated virus, to confer protection against the disease.

In physiology he carried out from 1871 to 1878 experimental inquiries upon the mechanism of circulation and of respiration, made an extensive investigation as to asphyxia, and was the first to show that the nerve fibres in the corona radiata of the cerebral hemispheres would, when locally excited, give rise to definite body movements. But his main work dealt

with the fundamental characters of those elementary processes which are displayed by the excitable tissues of both animals and plants when their activities are aroused by definite stimulation; he thus returned to the topic which had attracted him during his student life at Edinburgh. The published researches of his later years on this subject have become models for all subsequent work, commanding admiration on account of the completeness of their design, and carrying conviction through the security of their foundation, which rests on the solid ground of mensurable records. The electromotive phenomena displayed by active tissues appeared to him to furnish the most trustworthy of such records, provided that appropriate instrumental methods were employed in their investigation; these he made every effort to utilise, and for this end he introduced into physiological method the recording capillary electrometer. His publications on the electromotive phenomena of the beating heart, on similar phenomena in the excitable leaves of the Dionæa plant, in voluntary muscle, in the electrical organs of fishes, &c., are examples of his activity in this field.

In the last year of his life he was still engaged upon this engrossing subject, and was planning and supervising investigations for the further elucidation of the electromotive phenomena present in muscle when thrown reflexly into activity. This piece of work, and others on various subjects of like nature, remain in an unfinished state, but, though fragmentary, they are so suggestive that it may be hoped they will be included in a future collection of his numerous scientific papers.

In conclusion, reference must be made to that commanding influence which true greatness exerts over other scientific workers, moulding their thought, stimulating their powers, and enriching their lives. The factors which contribute to the wielding of this influence defy precise definition, since, apart from acknowledged achievement in science, their essence is to be sought for in certain mental, moral, and physical qualities. In Burdon-Sanderson's case conspicuous traits stamped him as a leader of men, for his inspiring personality, his extraordinary charm of manner, and his wonderfully expressive face made a profound impression even on those whom he casually met. But his students, using the term in its largest sense, were conscious that the real impression made upon them was the work of more potent factors; his courtesy to even the humblest worker, the sympathetic interest with which he followed all experimental work, the breadth of his view, the profundity of his knowledge, ever placed ungrudgingly at the disposal of everyone who sought his help, the genuine character of his devotion to scientific truth, and the unwavering firmness with which he advocated the use of experimental methods. All these combined to attract and hold the younger physiologists and pathologists, and since they realised that it was a delight to him to mix with younger men the influence he exerted was profound. He often expressed his intense satisfaction at the vast change of which he had been a witness, a change which has in thirty years advanced British physiology and pathology into the first rank. The name of Burdon-Sanderson will be permanently associated with this extraordinary advance, for it is generally recognised that by work, example, and precept he has contributed in a very special degree towards the creation in this country of that vigorous band of workers who have given English medical science such a wide reputation.

F. G.

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

THE anniversary meeting of the Royal Society was held on Thursday, November 30, when the report of the council was presented, the president delivered his address, and the new council already announced (p. 33), for the year 1906, was elected. In the evening the anniversary dinner was held at the Hotel Metropole, Lord Rayleigh, the newly-elected president, being in the chair.

The report of the council refers, among other subjects, to the Royal Society Catalogue of Scientific Papers, the International Catalogue of Scientific Literature, the Meteorological Office, tropical diseases, Antarctic work, seismology, the International Geodetic Association, Indian Trigonometrical Survey, Astrographic Chart, and the National Physical Laboratory. A few matters recorded in the report have not been announced or described in these columns, and may therefore be mentioned here.

At the beginning of August, the Treasury expressed willingness to place on the estimates a sum not exceeding 200*l.* as an annual national contribution toward the expenses of the central bureau of the International Seismic Organisation should the adhesion of Great Britain to the international scheme be agreed to. On November 2, the council, having received a report on the subject from the Society's seismological committee, agreed to recommend that H.M. Government should join the organisation, and advised that Prof. Schuster be appointed the representative of this country to the organisation. The Treasury has agreed to the continuation by Great Britain of its adherence to the Geodetic Convention of 1895 for a further period of ten years from January 1, 1907, and to a payment during that period of an annual subscription of 6000 marks. Also, at the instance of the Royal Society, the Treasury has undertaken that one-half the cost of printing the British section of the International Astrographic Catalogue executed under Prof. Turner's direction, within a limit of 1000*l.*, shall be met from public funds.

The report of the council concludes with an expression of appreciation of Sir William Huggins's services to the Society during the five years in which he held the office of president, and the announcement that Lord Rayleigh had accepted nomination as his successor.

In his presidential address, Sir William Huggins dwelt upon the influence which discoveries of science have had upon the general life and thought of the world, especially during the past fifty years, and the place that science should take in general education. Some extracts from the address are subjoined:—

The influence of science during the last fifty years has been in the direction of bringing out and developing the powers and freedom of the individual, under the stimulation of great ideas. To become all that we can become as individuals is our most glorious birthright, and only as we realise it do we become, at the same time, of great price to the community. From individual minds are born all great discoveries and revolutions of thought. New ideas may be in the air and more or less present in many minds, but it is always an individual who at the last takes the creative step and enriches mankind with the living germ-thought of a new era of opinion.

All influences, therefore, and especially all laws and institutions which tend to lose the individual in the crowd, and bring down the exceptional to the level of the average, are contrary to the irresistible order of nature, and can lead only to disaster in the individual and in the State.

I should not omit to mention the marvellous secondary effects of scientific discoveries upon the mental progress of

the civilised world which are being wrought by their practical applications to the cheapening of paper, and to improvements of the automatic printing-press, which, combined with the linking together of all parts of the earth by a network of telegraphic communications, put it in the power of even the poor of the realm to read daily the news of the world, and for a few shillings to provide themselves with a library of classical works. Of scarcely less educational influence upon the public mind are the new methods of photography and mechanical reproduction, by which pictures of current events and the portraits of those who are making contemporary history, and also copies of the world's masterpieces of painting and of sculpture, are widely disseminated with the cheap newspapers and magazines among the mass of the people.

Golden will be the days when, through a reform of our higher education, every man going up to the universities will have been from his earliest years under the stimulating power of a personal training in practical elementary science; all his natural powers being brought to a state of high efficiency, and his mind actively proving all things under the vivifying influence of freedom of opinion. Throughout life he will be on the best terms with nature, living a longer and a fuller life under her protecting care, and through the further disclosures of herself, rising successively to higher levels of being and of knowledge.

The importance to every man of a practical acquaintance with elementary science is obvious. Would it be thought possible that any nation could act so absurdly as to teach its children other languages, and leave them in complete ignorance of the tongue of the land in which they would have to pass their lives? Would it not then be incredible, if it had not become a too familiar fact, that the public schools have, until recently, excluded all teaching of the science of nature from their scheme of studies, though man's relation to nature is more intimate than to his fellow countryman? We live, move, and have our being in nature; we cannot emigrate from it, for we are part of it. Yet our higher education leaves men, who in other directions are well informed, much as deaf-mutes in the presence of nature. They do not hear her most imperative warnings, and can only get on haltingly in their everyday intercourse with the natural forces to which their lives are subjected, by means of the arbitrary signs of empirical custom. The recent introduction of some amount of science-teaching in our higher schools is quite inadequate, alike in kind and in degree. It can be only through a reform of the scheme of their examinations by the universities that we can hope to see science take the equal part with the humanities in general education to which she is entitled.

Two faculties of the mind which it is of the highest importance, especially in early youth, to enlarge and develop by exercise are wonder and imagination. Under the ordinary premature language-teaching of the grammar schools, even the wonder and imagination natural to young minds become so stunted in their growth as to remain more or less dormant throughout life. On the other hand, natural science brings them into full activity and greatly stimulates their development. Nature's fairy tales, as read through the microscope, the telescope, and the spectroscope, or spelt out to us from the blue by waves of ether, are among the most powerful of the exciting causes of wonder in its noblest form; when free from terror it becomes the minister of delight and of mental stimulation.

And surely the master-creations of poetry, music, sculpture, and painting, alike in mystery and grandeur cannot surpass the natural epics and scenes of the heavens above and of the earth beneath, in their power of firing the imagination, which, indeed, has taken its most daring and enduring flights under the earlier and simpler conditions of human life when men lived in closer contact with nature and in greater quiet, free from the deadening rush of modern society. Of supreme value is the exercise of the imagination, that lofty faculty of creating and weaving imagery in the mind, and of giving subjective reality to its own creations, which is the source of the initial impulses to human progress and development, of all inspiration in the arts, and of discovery in science.

Further, elementary science, taught practically with the aid of experiment during a boy's early years, cannot fail to develop the faculty of observation. However keen in vision, the eyes see little without training in observation by the subtle exercise of the mind behind them. From the humblest weed to the stars in their courses, all nature is a great object-lesson for the acquirement of the power of rapid and accurate noting of minute and quickly-changing aspects. Such an early training in the simpler methods of scientific observation confers upon a man for life the possession of an inexhaustible source of interest and delight, and no mean advantage in the keen competitions of the intellectual activities of the present day.

Training in the use of the eyes develops, at the same time, alertness of the intelligence, and suppleness of the mind in dealing with new problems, which, in after life, will be of great value in facing unforeseen difficulties of all kinds, which are constantly arising.

Science, practically taught, does more, for, under the constant control of his inferential conclusions by the unbending facts of direct experiment, the pupil gradually acquires the habit of reasoning correctly from the observations he makes. In particular, he learns the most precious lesson of great caution in forming his opinions, for he finds how often reasoning, which appeared to him to be flawless, was not really so, for it led him to wrong conclusions. Further, from the constant study of nature, the student comes so to look at things as almost unconsciously to discriminate between those which are essential and those which are only accidental, and so, gradually, to acquire the faculty of classing the facts of experience, and of putting them in their proper places in a consistent system or theory. Are there any other studies, it may be asked, by which, in the same time, a young mind could develop an equally enlarged capacity for correct reasoning and acquire so wide an outlook? Yet, notwithstanding the immense intrinsic value of its teaching, science is but one of the studies which are necessary for a wide and liberal education. Intellectual culture, or, in other words, the whole mind working at its best, requires, besides the training of all its powers harmoniously by the study of nature, an acquaintance with many other kinds of knowledge, especially of human history and the development of human thought, and of the human arts. Humanistic studies and experimental science are equally essential, and, indeed, complement each other. Either alone leaves the mind unequally developed, and its whole attitude one-sided, and so produces a narrow type of mind, which is incapable of taking a wide view even of its own side of thought, and has but little sympathy with any subject outside it.

Improved methods of teaching the classical languages, which would permit of the beginning of the study of them at a later age, would leave ample time for an early training in experimental science, which must soon come to be recognised as an essential part of all education.

In future, no grammar or higher school should be considered as properly provided for unless furnished with the necessary apparatus for teaching experimentally the fundamental principles of mechanics, physics, and biology. The pupils should have the use of a small astronomical telescope, and of microscopes for biological work. Such apparatus and instruments can now be purchased at a very small cost.

Clearly, it is only by such a widening of the general education common to all who go up to the universities, before specialisation is allowed, that the present "gap between scientific students careless of literary form, and classical students ignorant of scientific method" can be filled up, and the young men who will in the future take an active part in public affairs, as statesmen and leaders of thought, can be suitably prepared to introduce and encourage in the country that fuller knowledge and appreciation of science which are needed for the complete change of the national attitude on all science questions, which is absolutely necessary if we are to maintain our high position and fulfil our destiny as a great nation.

This address was followed by the award of the medals.

Copley Medal.

The Copley medal is awarded to Prof. Dmitri Ivanovitch Mendeléeff, For.Mem.R.S., for his contributions to chemical and physical science.

Prof. Mendeléeff, born at Tobolsk, in Siberia, in 1834,

stands high among the great philosophical chemists of the last century. As early as 1856 he published his own conclusion that paramagnetic elements have, in general, smaller molecular volumes than diamagnetic elements, and confirmed Avogadro's view that electropositive elements have larger molecular volumes than electronegative ones, both of them results specially interesting in connection with modern views of molecular structure. At that time he had already assimilated and utilised the views of Laurent, Gerhardt, and Williamson on molecular constitution, which made such slow progress in general. Since then, in the words of Dr. Thorpe (NATURE, June 27, 1889), "There is, in fact, no section of chemical science which he has not enriched by his contributions"—mineralogy, chemical geology, organic chemistry, the nature and industrial importance of petroleum, but, above all, physical chemistry and chemical philosophy.

Quoting again from Dr. Thorpe:—"His 'Principles of Chemistry,' published in 1889, and repeatedly reprinted, is a veritable treasure-house of ideas, from which investigators have constantly borrowed suggestions for new lines of research. This book is one of the classics of chemistry; its place in the history of science is as well assured as the ever-memorable work of Dalton." In the course of its preparation he developed the great generalisation known as the periodic law of the elements, with which his name will ever remain most closely associated, especially as a weapon for predicting new elements, and for which he has received the Davy medal of this society, as also have Newlands and Lothar Meyer for their independent advances in the same direction.

This law has changed the face of chemistry by imparting to the study of its numerous independent elements that close inter-connection which is a characteristic of advanced physical theories.

Royal Medals.

A Royal medal is awarded to Prof. John Henry Poynting, F.R.S., on account of his researches in physical science, especially in connection with the law of gravitation and the theories of electrodynamics and radiation.

Prof. Poynting is distinguished both in theoretical and experimental physics. His memoir, *Phil. Trans.*, 1884, "On the Transfer of Energy in the Electromagnetic Field," contains the fundamental proposition which is now universally known as Poynting's theorem. It was followed in *Phil. Trans.*, 1885, by a paper "On the Connection between Electric Current and the Electric and Magnetic Inductions in the Surrounding Field," which works out the current circuit on the supposition of motion of what are now called Faraday tubes. These papers served greatly to elucidate Maxwell's theory, and give a representation of the physical nature of the electric field which is now widely utilised. His long-continued experimental and theoretical researches on the constant of gravitation and on the mean density of the earth are reported in a paper in the *Phil. Trans.*, 1892, and in the Adams prize essay for 1893. Closely related to this subject is an experiment in search of a directive action of one quartz crystal on another, *Phil. Trans.*, 1899, which, though leading to a negative result, is a model of the application of refined methods to a physical research of great delicacy. His recent paper, *Phil. Trans.*, 1903, "On Radiation in the Solar System, its Effect on Temperature, and its Pressure on Small Bodies," is of great interest and significance in cosmical physics. He is the author of various theoretical papers on physicochemical subjects, such as change of state and osmotic pressure, which are conspicuous for originality of conception and clearness of exposition.

The other Royal medal is awarded to Prof. Charles Scott Sherrington, F.R.S., for his work on the central nervous system, especially in relation to reflex action.

Prof. Sherrington has published a series of important papers upon the structure and function of the brain and spinal cord. In the earlier of these he chiefly investigated the course of the several groups of nerve fibres by means of the degeneration method. Passing from the study of structure to that of function, he discovered that removal of the fore brain causes a widespread rigidity of certain muscles, which he called decerebrate rigidity. In the state of decerebrate rigidity, the ordinarily observed reflexes of the body become profoundly altered, and a study of the normal and abnormal reflexes led him to the observation that contraction of one muscle is commonly associated with inhibition of its antagonist. Upon this he formulated the law of the reciprocal action of antagonistic muscles, which is now accepted as of fundamental importance in the coordination of muscular movement. A further study of reflex actions led him to lay down certain general principles with regard to them. One principle deserves especial mention, namely, that hurtful stimuli applied to the skin produce a different form of reflex from that given by stimuli which are not hurtful. This has served as a basis for further investigation on the character of the nerve impulses conveyed by different nerve-endings, on the course taken by the impulses, and on their central connections.

In recent years a considerable amount of work has been done in mapping out the areas of the skin supplied by each of the cranial and spinal nerves. This work, essential both to physiology and to clinical medicine, received its chief impetus and most weighty contribution from the careful and detailed observations of Prof. Sherrington.

The researches of Prof. Sherrington and Dr. Grünbaum, on the localisation of the excitable areas in the cortex of the cerebral hemispheres in the higher apes, have resulted in placing the "motor area" in this animal entirely in front of the central sulcus. The result is now generally accepted as true also for the brain of man—a point of great importance in the surgery of the brain.

Prof. Sherrington's researches have dealt with a number of subjects cognate with that of the central nervous system. He has shed light on questions connected with the afferent nerves of skeletal muscle, the efferent nerves of the arrectores pilorum and of the cranial blood-vessels, the innervation of various viscera, the trophic centre of the fibres of the roots of the spinal nerves, the knee jerk, and with the physiology of vision.

Davy Medal.

The Davy medal is awarded to Prof. Albert Ladenburg, on account of his researches in organic chemistry, especially in connection with the synthesis of natural alkaloids.

Thirty years ago, when the validity of Kekulé's famous formula for benzene was the subject of much discussion, Ladenburg was the first to prove, by laborious research, the important proposition that the six hydrogen atoms in the hydrocarbon are similarly situated and discharge the same functions, and hence that three, and only three, *di*-substitution derivatives can exist.

He has also devoted many years to the study of the natural alkaloids. This pioneer work, attended by many experimental difficulties, was rewarded by success in the synthesis, for the first time in 1886, of an optically active compound identical with the alkaloid coniine existing in the hemlock plant. Since that time he has largely added to our knowledge of the chemistry of hyoscyamine, atropine, and other alkaloids of the mydriatic class.

Hughes Medal.

The Hughes medal is awarded to Prof. Augusto Righi, for his experimental researches in electrical science, including electric vibrations.

Prof. Righi has been for many years a prominent and active worker in the sciences of light, electricity, and magnetism.

Among the subjects which have engaged his attention are the Hall effect, and the change of electric conductivity of bismuth in a magnetic field. At an early period he carried out an elaborate investigation on the reflection of light at the surface of a magnetised body, repeating and extending Kerr's observations with more powerful apparatus; in particular, he showed how the amount of the rotation of the plane of polarisation depends upon the wave-length of the light.

A valuable series of papers related to phenomena produced by the ultra-violet rays, including the first discovery of the discharge of negative electricity from a freshly polished zinc surface under their influence. He has also investigated the potential in the neighbourhood of the kathode in a Crookes's tube, and made many experiments on the spark discharge in gases and the action of the Röntgen rays.

His work on electric radiation has been collected in a book, "L'Ottica delle oscillazioni elettriche," Bologna, 1897. He rendered fundamental service to exact experiment on this subject by simplifying the practical conditions of the problem; and he applied his improved apparatus to numerous investigations on the behaviour of electromagnetic waves, of short and therefore manageable wave-length, under very varied conditions, on their absorption, polarisation, reflection and refraction, and on the behaviour of dielectrics in the field of radiation. This work entitles him to a high place among those who developed the lines of experimental investigation opened up by the great discoveries of Hertz.

More recently he has contributed substantially to the study of the phenomena of radio-activity and the related ionisations.

THE DEATH-KNELL OF THE ATOM.[1]

Old Time is a-flying; the atoms are dying;
Come, list to their parting oration:—
"We'll soon disappear to a heavenly sphere
On account of our disintegration.

"Our action's spontaneous in atoms uranious
Or radious, actinious or thorious:
But for others, the gleam of a heaven-sent beam
Must encourage their efforts laborious.

"For many a day we've been slipping away
While the savants still dozed in their slumbers;
Till at last came a man with gold-leaf and tin can
And detected our infinite numbers."

Thus the atoms in turn, we now clearly discern,
Fly to bits with the utmost facility;
They wend on their way, and in splitting, display
An absolute lack of stability.

'Tis clear they should halt on the grave of old Dalton
On their path to celestial spheres;
And a few thousand million—let's say a quadrillion—
Should bedew it with reverent tears.

There's nothing facetious in the way that Lucretius
Imagined the Chaos to quiver;
And electrons to blunder, together, asunder,
In building up atoms for ever!

W. R.

[1] Sung at the Chemical Laboratory dinner at University College, November 17.

NOTES.

THE Hayden memorial gold medal has been awarded by the Academy of Natural Sciences of Philadelphia to Mr. C. D. Walcott, director of the U.S. Geological Survey, in recognition of the value of his individual contributions to geological science.

THE University of Basle, to which the late Prof. Dr. Georg W. A. Kahlbaum was attached for nearly twenty years, has received the sum of 100,000 francs from the mother of the deceased professor. Further, Prof. Kahlbaum's scientific library and physical instruments are also to be handed to the university.

FROM Berlin we learn, according to the *Chemiker-Zeitung*, that the German State grant for the support of scientific, technical, and similar undertakings is to be increased by 115,000 marks. The sum of 179,500 marks is to be spent upon increasing the accommodation for the permanent exhibition devoted to the interests of the working classes; 120,000 marks to be a first instalment for an investigation of sleeping sickness; 30,000 marks to be devoted to the development of the *Starkstrom*-laboratory of the Reichsanstalt; 43,850 marks to be contributed to the kite station on Lake Constance for experimental investigations of the higher air strata.

THE annual conference of the Pharmaceutical Society will be held in Birmingham in the week beginning July 23, 1906.

FOR the erection of a monument to Franz Reuleaux in the Charlottenburg Technical School, an appeal for subscriptions has been issued by the engineering department of the school.

MR. F. W. DYSON, F.R.S., chief assistant, Royal Observatory, Greenwich, has been appointed Astronomer Royal for Scotland, and also professor of practical astronomy, Edinburgh University, in succession to the late Dr. Copeland.

AN exhibition of electrical, optical, and other physical apparatus has been arranged by the Physical Society, and will be held on Friday evening, December 15, at the Royal College of Science, South Kensington. Admission will be by ticket only.

IT is reported, *Science* says, that the Mexican Astronomical Society has awarded the prize offered by the Bishop of Leon for some notable astronomical discovery to Prof. W. H. Pickering, of Harvard College Observatory, for the discovery of the tenth satellite of Saturn.

AN archæological museum, which will devote special attention to Indo-Chinese matters, has been established by the French Government at Pnompenh. The museum will be under the scientific control of the École française d'Extrême-Orient, the chief of the archæological department of which school will act as director of the new museum.

A DESCRIPTION is given in the *Engineer* of December 1 of some interesting machine-tools, formerly the property of James Nasmyth, lately placed on view in the southern galleries of the Victoria and Albert Museum. Although associated primarily with the invention of the steam-hammer, James Nasmyth did valuable work in the improvement of machine-tools.

AN extensive landslip has occurred in the Danish island of Möen, destroying part of the beautiful scenery along Lille Klint. From the beach, steep slopes of Boulder-clay, thickly wooded, rise about 250 feet. The right bank of the valley from Liselund Chateau, and the coast-cliff for some 400 yards to the south of it, in all some fifteen or twenty acres of woodland, are described as having sunk bodily. The sea had been encroaching, but underground water is regarded as the cause.

A *Times* correspondent reports that a local Greek newspaper publishes details of the earthquake of November 8, which caused great damage to the various monasteries on Mount Athos. The shocks, which were extremely violent, occurred in the night. None of the monasteries escaped without serious injury. The shocks were not confined to the colony of monks. At Caryes the post-office, the police station, and other public buildings have been ruined, and at Cassandra, Jerissos, Gomate, and other villages within the districts affected the churches and many houses have been destroyed.

IN the course of a lecture delivered at the Armstrong College, Newcastle-on-Tyne, on December 2, the Hon. C. A. Parsons, F.R.S., dealt with the application of turbines to Atlantic passenger steamers, and described the

recent trials of the Cunarder *Carmania* with turbine engines, and her sister ship, *Caronia*, with reciprocating engines, the latter being one of the most economical vessels ever built. The *Carmania* beat the *Caronia* by one knot, and was at least 16 per cent. more economical than her sister vessel driven by reciprocating engines. The *Carmania* is the first example on so large a scale, and it may be reasonably expected that improvements in detail will increase still further the excellent results she realised.

MAJOR MOODIE, Governor of Hudson Bay, has received a communication, dated May 22 last, from Captain R. Amundsen's Norwegian Expedition to the North Pole. The *Gjoa*, with the expedition on board, spent last winter in Simpson Strait, King William's Land, 400 miles north of Fullerton. Captain Amundsen dispatched letters from Fullerton in November, 1904, reporting the expedition well, but short of dogs. The messenger reached Governor Moodie's headquarters on March 18 of this year, and on March 26 he started back with ten dogs. The messenger reached Captain Amundsen's party on May 22, and then returned to Fullerton with a second letter. This reported that the observations of the party had been conducted undisturbed since the establishment of the magnetic station in October, 1903.

AT a meeting of the council of the Invalid Children's Aid Association, held last week, Sir William Broadbent delivered an address on the tuberculous children of the metropolis, in which he pointed out that while consumption, the most prevalent form of tuberculous disease, has steadily diminished year by year for the last thirty years, there has been no corresponding diminution in the death-rate of tuberculous affections specially incident to infancy and early childhood. He strongly urged the establishment of country and sea-side homes where delicate children in the pre-tuberculous stage, or those actually suffering from tuberculosis, could receive the benefits of the open-air treatment. After alluding to the sanitary defects of tenements in which the poor too often have to live, he pointed out that the greatest safeguard against tuberculosis in early life, and against infantile mortality generally, is that the child should be suckled by the mother.

THE council of the Iron and Steel Institute has arranged that the annual general meeting of the institute shall be held in London on May 10–11, 1906. In place of the usual autumn meeting, a joint meeting with the American Institute of Mining Engineers will be held in London on July 23–28. It is intended during the week following to give the American visitors an opportunity of seeing some of the iron-making districts. It is anticipated that the visiting party will include many of the leading ironmasters who entertained the Iron and Steel Institute in America in 1890 and 1904. The Lord Mayor of London has consented to act as chairman of the London reception committee, and to give an evening reception at the Mansion House.

LECTURES on agricultural subjects are given in connection with the County Technical Laboratories, Chelmsford, on Friday afternoons, which is the market day of the town. The lectures last about half an hour, and are intended for farmers and others interested in agriculture. A discussion follows the lecture. The subjects for the December meetings, with the lecturers dealing with them, are as follows:—The field culture of the potato, by Mr. A. Steel; England as a producer of sugar from home-grown sugar beetroot, by Mr. Sigmund Stein; some agricultural facts and figures, by Mr. R. H. Rew. This excellent plan of making it easy for farmers to hear of the results of modern agricultural research deserves to be successful, and could be adopted with advantage in other agricultural centres.

AT a general monthly meeting of the members of the Royal Institution, held on Monday, special thanks were returned to Dr. Ludwig Mond, F.R.S., for his donation of 500*l*. to the fund for the promotion of experimental research at low temperatures. It was announced that the managers had elected Prof. W. Stirling Fullerian professor of physiology. The following are among the lecture arrangements at the Royal Institution before Easter:—A Christmas course of six illustrated lectures, adapted to a juvenile auditory, by Prof. H. H. Turner, on astronomy; Prof. E. H. Parker, three lectures on impressions of travel in China and the Far East; Prof. William Stirling, six lectures on a physiological subject; Dr. J. E. Marr, three lectures on the influence of geology on scenery (the Tyndall lectures); Mr. Benjamin Kidd, two lectures on the significance of the future in the theory of evolution; Mr. Francis Darwin, three lectures on the physiology of plants; Prof. B. Hopkinson, three lectures on internal combustion engines; Mr. J. W. Gordon, two lectures on advances in microscopy; and Prof. J. J. Thomson, six lectures on the corpuscular theory of matter. The Friday evening meetings will commence on January 19, when Prof. J. J. Thomson will deliver a discourse on some applications of the theory of electric discharge to spectroscopy. Succeeding discourses will probably be given by Prof. S. P. Thompson, Mr. H. F. Newall, Mr. W. C. D. Whetham, Dr. R. Caton, Dr. Hutchison, Sir Andrew Noble, Bart., Prof. P. Zeemann, Mr. W. B. Hardy, and others.

THE Russian physiologist, Prof. Iwan Michaelowitsch Ssetschenoff, emeritus professor of the University of Moscow, who died on November 15, was born in 1829. He first attended an engineering school in St. Petersburg, but subsequently took up medicine, and, after passing his final examination in Moscow in 1856, studied for some time in Germany. By his interesting paper on brain reflex he first attracted the serious attention of his colleagues of the Medico-chirurgical Academy in St. Petersburg, in which he was appointed an assistant professor of physiology in 1860, but on account of the strict censure to which his further work was submitted, Ssetschenoff published the results of his scientific investigations in Germany. A pupil of Du Bois-Reymond, Helmholtz, Hoppe-Seyler, and Ludwig, he always remained in direct connection with European scientific circles. The greatest services which Ssetschenoff rendered to science lie in the province of physiological chemistry, as, for instance, his works on the absorption of carbon dioxide by the blood. A complete list of his numerous researches would clearly testify to his many-sidedness and breadth of view. Moreover, he earnestly endeavoured to popularise his special science to the Russian mind by presenting it in an easily intelligible form in such well written and well reviewed works as his "Physiological Studies," "Physiology of the Vegetable Processes," "Psychological Studies," &c. In 1870 Ssetschenoff was appointed professor of physiology in the University of Odessa, and in 1876 to a similar post in St. Petersburg, which he held until 1889. He then went to Moscow, where he first acted as privatdocent and afterwards (1891) as professor, retiring in 1896.

IN the second part of his article on the histology of cartilage and kindred tissues, published in vol. lxxx., part ii., of the *Zeitschrift fur wissenschaftliche Zoologie*, Mr. J. Schaffer discusses these structures in the hag-fish (Myxine), with special reference to the cranial skeleton of that genus, adding an appendix on the cartilage of the

lampreys. The organisation of the "bear-animalcules," or Tardigrada, those microscopic creatures found in damp moss and the gutters of roofs, forms the subject of an article by Mr. A. Basse; while the third and last communication is the first portion of a memoir by Mr. S. Hlava on the Radiata, the author dealing in this instance with the anatomy of *Conochiloides natans*.

IN an important article on the cranial nerve-components of the lamprey (Petromyzon), published in Gegenbaur's *Morphologisches Jahrbuch*, vol. xxxiv., part ii., Mr. J. B. Johnston shows that the general arrangement is similar to what obtains in fishes, although with certain markedly primitive features. As the result of a study of the visual organs of the ascidians of the Salpa group, Mr. W. Redikorzen arrives at the conclusion that the primitive chordates possessed a series of paired organs of this nature extending from the head to the tail—one pair to each body-segment. Moreover, the pineal eye was certainly in the first instance a dual structure, but later its two elements coalesced and subsequently degenerated. This segmental ocular type has entirely disappeared from vertebrates, and is now represented only by traces among the lower groups. The other papers in the same issue include one by Mr. T. Mollison on the dorsal gland of Dendrohyrax, and a second by Mr. J. Bohm on the reproductive organs of the sheep.

IN the November issue of the *Zoologist* Mr. G. Renshaw resumes his interesting series of "obituaries" of exterminated animals, dealing in this instance with the Réunion starling, the sole representative of the genus Fregilupus. Easily recognised by its parti-coloured plumage and long crest, this bird was probably discovered by Flacourt in the middle of the seventeenth century. In the early part of the last century it was abundant, but in 1833 had become extremely scarce, and by about 1860 had probably ceased to exist even in its last refuge in the interior of the island. Twenty-one skins, of which one is in the Natural History Museum (although not shown to the public), and two skeletons, of which one is at Cambridge, are all the relics of this interesting species Mr. Renshaw can identify. In another paper Dr. J. Murie discusses the flying-fish captured in September last in a back-water connected with the Medway estuary. It is believed to belong to *Exocoetus lineatus*, a species not previously recorded as an occasional straggler into British waters.

THE almost complete shell of a large Cretaceous turtle from Kansas has afforded Mr. G. R. Wieland the opportunity of enlarging our knowledge of the extinct genus Toxochelys, his communication on the subject being published in the November issue of the *American Journal of Science*. The structure of the shell agrees with that of certain extinct representatives of the Chelonidæ (Lytoloma), but the skull approximates to that of the Chelydridæ. That the genus should be classed with the true turtles the author is convinced, although he believes the limbs to have been independently modified for swimming. The most interesting part of the paper relates, however, to certain bony elements overlying the junctions between the neural bones of the carapace, and it is suggested that these, which may have been more extended in other types, may represent the mosaic-like shell of the leathery turtles (Dermochelyidæ). If this suggestion be well founded, the puzzle of the origin of the carapace of Dermochelys will be practically solved.

THE *Comptes rendus* of the zoological congress held at Berne last year contains the full report of a series of experiments undertaken by Mr. H. Piéron with the view of ascertaining the seat of the recognition-sense among ants. The theory of a "language-sense" resident in the antennæ is rejected by the author, to some extent on the ground that these organs are employed in feeling objects of every kind, animate and inanimate. On the other hand, it is inferred that these organs are endowed with an olfactory sense, on which depends mutual recognition among ants. As is well known, ants not only of different species, but of different communities of the same species, display marked hostility to one another. By making an infusion of ants of one particular community, and anointing the neuters of another community with this infusion, it was found that in most instances the hostile ants thus treated were not attacked by the members of the community from which the infusion was made, this immunity from attack lasting only so long as the influence of the infusion persisted. On this and other experiments of a kindred nature the author's conclusions are mainly based. But to connect these experiments with the antennæ, an ant was deprived of those appendages, when it was found to attack friends and foes alike. Mr. Piéron has also favoured us with a copy of another paper, from the *Bulletin de l'Institut psychologique* for 1904, on the *rôle* of the muscular sense in determining orientation among ants.

THE experimental station at Peradeniya, Ceylon, has rapidly grown into public favour, and large numbers of agriculturists visit the station to get practical lessons in their craft. From the annual report of the controller, Mr. H. Wright, published as vol. iii., No. 10, of the Circulars of the Royal Botanic Gardens, it will be seen that a considerable amount of time has been devoted to the subject of green manures. While the first object consists in growing a crop to turn into the soil, the additional advantage possessed by leguminous plants of fixing free nitrogen has led to their almost exclusive use. In a tropical country green manures also prevent erosion of the soil by heavy rain and the baking of the surface by the hot sun. *Crotalaria striata* is strongly recommended for tea estates, since it produces a heavy crop. A plant of a different kind is the thornless dadaps, *Erythrina lithosperma*, from which cuttings five feet long planted in the rainy season gave a substantial yield. The Pondicherry variety of groundnut has also proved useful.

IN the report of the director of the Mineralogical Survey contained in the Ceylon Administration Reports much valuable information is given by Mr. A. K. Coomaraswamy and Mr. James Parsons regarding the occurrence of corundum, of minerals containing rare earths, of precious stones, of crystalline limestone, of mica, and of graphite. With the aid of numerous illustrations, interesting descriptions are also given of the native Sinhalese manufacture of iron and steel, and of the washing of gem-bearing gravels. The minerals containing rare earths have been derived from intrusive granite rocks. Thorianite containing more than 70 per cent. of thoria and 12 per cent. to 15 per cent. of uranium oxide occurs in moderate quantities near Kondrugala. The whole amount obtained hitherto is less than 30 cwt., and it is doubtful whether any very extensive deposit occurs. Thorite, allanite, and minerals of the samarskite group have also been found. The gems met with are transparent and well coloured varieties of corundum, spinel, zircon, tourmaline, topaz, garnet, chrysoberyl, cordierite, amethyst, felspar, and beryl. Many of these are exhibited in the mineral gallery of the museum attached to the survey, and the director is making strenuous endeavours to get together a thoroughly representative collection which can always be consulted by visitors to Ceylon.

A useful series of memoirs is being published monthly in the *Bulletin du Musée océanographique de Monaco*. In No. 44, for October, Prof. Hergesell discusses some future problems of maritime meteorology; by this name he refers to the meteorological phenomena of the atmosphere over the oceans. He remarks that if our knowledge is well advanced over the land, it is much less so over the oceans, and that our knowledge over the sea is due to a great extent to such expeditions as those of the *Challenger*, *Gazelle*, and *Valdivia*. Others might have been cited, *e.g.* the Austrian expedition of the *Novara* in 1857–9. But we cannot help remarking that the meteorology over the oceans might be considered as fairly well defined, owing to the labours during the last fifty years of such men as Maury in the United States, FitzRoy and Toynbee in this country, Leverrier and Brault in France, Buys Ballot and Andrau in Holland, Neumayer in Germany, and, of course, including their successors in the central meteorological offices of the respective countries. But while much has been done in the investigation of the upper air over the land by the use of kites and balloons, both manned and unmanned (or "sounding" balloons), and some surprising results have been obtained, little has yet been done in this respect over the oceans. The balloon ascents over the land have shown, for instance, that there is a warm stratum of air at a height of about 11 kilometres; that the decrease of temperature with altitude ceases more or less abruptly, and that the temperature actually increases for a further height of several kilometres. This zone of inversion is probably intimately connected with the general circulation of the atmosphere, and it is most important to know the exact conditions over the ocean, especially in equatorial and certain other localities. We are glad to see that the Prince of Monaco has succeeded in interesting the Emperor of Germany in these questions, and that the cooperation of the German Navy in elucidating them appears to be assured.

Of the papers read at the optical convention in June last, a number of those having a special bearing on the microscope are abstracted in the *Journal of the Royal Microscopical Society* for October. In one of these papers, dealing with equivalent planes of optical instruments, Mr. Conrad Beck gives a simple explanation of the why and wherefore of the particular arrangement of lenses adopted in the compound microscope. A high-power microscope may have an equivalent focal length of only a few thousandths of an inch, but the plan of using lenses separated by large intervals gives an instrument in which the equivalent planes (*i.e.* the principal planes) are outside the system of lenses, thus allowing sufficient working distance between the front lens and the object.

In connection with Prof. Paul Harzer's recent communication to the British Association (*vide* Nature, October 26), we read with considerable interest an address delivered by him at the University of Kiel on the Emperor's last birthday, published by Lipsius and Tischer, of Kiel, dealing with the development of exact sciences in ancient Japan. In the Imperial Library of Tokyo there are no less than 2000 written and printed Japanese mathematical works extending back to the year 1595; and it is scarcely remarkable that the determination of the "Ludolphian Number" (Pi) played a prominent part in the thoughts of early Japanese mathematicians. In 1627 the approximation 79/25 was known, while in the second half of the seventeenth century values had been obtained which are correct to 9 or 10 places. The well known value 355/113 was known in 1709, and in 1722 and 1739 values correct to 49 and 51 places had been found. Among the early "circle squarers" Kowa Seki (1642–1708) occupied a leading place. His methods, which were applicable to circular arcs generally, depended on successive bisection, but in solving the quadratic equations by means of series the binomial expansion of the square root was used. During the eighteenth century four series for Pi were known to Naomaro Ajima, who also dealt with the ellipse. At the beginning of the nineteenth century Enzo Wada was acquainted with the catenary and cycloid, and it now appears proved that Seki and his immediate successors studied the binomial theorem, theory of numbers, the properties of maxima and minima, determinants, and spherical trigonometry. Of geodetical observations we have records dating from 1613, and these culminated in the measurements of arcs of the meridian by Ino Chukei (?) in 1800–1818. On the other hand, even as late as 1895, Prof. Harzer finds complaints of the neglect of higher mathematical study in Japan. The question as to how far the ideas of the early Japanese mathematicians were imported from the west through the medium of the Dutch trading ships or other means occupies a prominent part in Prof. Harzer's dissertation.

The twenty-fifth number (n.s.) of the *Transactions of the Oxford University Junior Scientific Club* contains, in addition to a list of the officers and new members and balance sheet, a paper by Mr. A. F. Walden on some recent views on the constitution of inorganic compounds, which gives an account of Werner's ideas as to the nature of complex cobalt and chromium salts. Mr. A. S. MacNalty deals with trypanosomiasis and sleeping sickness.

In No. 18 of the *Revue générale des Sciences* M. Bernard Brunhes, director of the Observatory of Puy-de-Dôme, gives an interesting account of recent work on terrestrial magnetism in central France. Notice is taken of the anomalies met with by workers in other countries, and particular emphasis is laid on the tendency of magnetic rocks to produce these effects. The Puy-de-Dôme affords an especially good example of the influence of magnetic rocks on the terrestrial magnetism of a district. A description is given of the method adopted in measuring the declination and inclination due to the permanent magnetisation of the specimens of rock selected for experiment.

The delegates of the Clarendon Press, Oxford, have published in pamphlet form, at sixpence net, an addendum to Mr. J. Cook Wilson's "On the Traversing of Geometrical Figures," which was reviewed in the supplement to our issue of October 19 (p. vi).

We have received from Messrs. A. Gallenkamp and Co., Ltd., of Sun Street, Finsbury Square, London, a copy of the fifth edition of their general chemical and scientific apparatus catalogue, which has been arranged to meet the requirements of the session 1905–6. The catalogue runs to 534 pages, and is profusely illustrated with clear and helpful illustrations. The arrangement of prices and details of sizes and similar facts in a simple tabular form throughout, and the concisely expressed descriptions of the forms of apparatus available, reduce the trouble of reference to a minimum. There is a good index provided also. Special attention may be directed to the section giving particulars of many forms of electrochemical apparatus, which should prove of interest to teachers and students of electrochemistry. The catalogue is worth examination by teachers who have charge of chemical and physical laboratories, and also by men of science engaged in research work. The excellence of this and other similar catalogues which have come before us recently is instructive evidence of the progress which has been made in the teaching of science in our schools and colleges.

OUR ASTRONOMICAL COLUMN.

COMET 1905*b*.—Further observations of this comet are recorded in No. 4056 of the *Astronomische Nachrichten*. As an error was made in the Bamberg record of R.A. on November 18, it became necessary for Herr Ebell to recalculate his elements and ephemeris, and the amended results are contained in Circular No. 81 from the Kiel Centralstelle. The corrected elements are as follows:—

$$T = 1905 \text{ October } 25{\cdot}7163 \text{ (Berlin).}$$

$$\left.\begin{aligned} \omega &= 132^\circ\ 34'{\cdot}9 \\ \Omega &= 222\ 55{\cdot}0 \\ i &= 140\ 37{\cdot}1 \end{aligned}\right\} 1905{\cdot}0$$

$$\log q = 0{\cdot}02188$$

The new ephemeris gives the position of the comet, at 12h. M.T. Berlin, on December 10 as $\alpha = 23$h. 30m. 53s., $\delta = -7^\circ\ 24'{\cdot}1$, but, as its brightness at that time will be only 0·07 of its brightness when discovered (mag. 7·5), the object will be a very difficult one to observe.

THE ANOMALOUS TAILS OF COMETS.—In No. 4, vol. xxii., of the *Astrophysical Journal* Prof. Barnard discusses the anomalous forms presented by the tails of comets. The generally accepted idea is that the tails are produced by the sun's repulsive force acting on the cometary matter, but, from a study of a number of photographs—more especially of Brooks's (1893) comet—Prof. Barnard has arrived at the conclusion that too much importance is attached to this cause, and that the eruptive action of the comet itself, and the active interference of external matter, should also be included amongst the tail-producing causes. Short, straight, minor tails, issuing from the nucleus at considerable angles to the main tail, seem to corroborate the existence of the comet's own eruptive force, or, at least, of some force in addition to that supplied by the sun.

The rapid deflections and distortions of the tail or tails, as in Brooks's comet, suggest the existence of some resisting medium which is not evenly distributed throughout interplanetary space, and such a medium would also explain the anomalous brightening up of some comets (*e.g.* Sawerthal's, May, 1888) and the disruption of such a comet as Biela's.

Finally, Prof. Barnard suggests that all bright comets possessing tails should be photographed hour by hour, as the day by day photographs hitherto obtained are separated by intervals so long that the changes recorded are not necessarily connected.

NOVA AQUILÆ NO. 2.—A number of photographs of the region about Nova Aquilæ, taken with the Bruce telescope, and with the 24-inch reflector of the Yerkes Observatory, are discussed by Mr. J. A. Parkhurst in the November *Astrophysical Journal*. These show that in the spring and summer of 1904 the Nova was at least fainter than the fifteenth magnitude.

The final mean value obtained for the position of the Nova for 1900 was

R.A. = 18h. 56m. 48·96s., dec. = $-4^\circ\ 35'\ 20''{\cdot}3$,

and a comparison of the images on different plates showed that the Nova was only slightly coloured.

A reproduction of one of the photographs taken with the 24-inch reflector (exposure, three hours) shows that the Nova is situated in a dark lane, almost devoid of stars, in a very rich field in the Milky Way, and also illustrates, in a very striking manner, the connection of Novæ with the galaxy.

CATALOGUE OF BINARY STAR ORBITS.—The results of a critical study of all published double-star orbits are published in Bulletin No. 84 of the Lick Observatory by Prof. R. G. Aitken.

The catalogue is divided into two lists, of which the first, relating to fifty-three stars, contains the elements of those orbits which Prof. Aitken considers to be fairly trustworthy. The second contains the names, the period, and the name of the computer of ninety-one stars of which Prof. Aitken considers the published orbits are too untrustworthy to be of any practical value.

A number of critical and explanatory notes relating to some of the individual stars accompany Prof. Aitken's catalogue.

INDIAN METEOROLOGY, 1892–1902.[1]

SIR JOHN ELIOT, in discussing recent meteorological phenomena, says:—"The period 1892–1902 was unique in the meteorology of India for the magnitude and persistence of the variations of rainfall, cloud, humidity and temperature from the normal."

This period can be divided into two parts, abnormal in opposite directions:—1892–4 characterised by excess of rain, cloud and humidity, and a reduced temperature, and 1895–1902 characterised by deficient rainfall, less cloud, drier air, and an average temperature above the normal.

The normal rainfall for three years (taking the average of 450 selected stations) is 123 inches, while the total rainfall for the period 1892–4 was 143·5 inches, an excess of 20·5 inches. The actual rainfall for the eight years 1895–1902 was 303·8 inches against the normal 328·7 inches, a deficiency of 24·9 inches.

During two years of this dry period the deficiency was so great over certain areas as to cause very severe droughts, which in turn caused famines. These two famines were, both in affected area and affected population, the worst during the last 150 years. The drought of 1896 and the famine of 1897 afflicted the United Provinces, Central Provinces, Central India, and Rajputana, an area of 300,000 to 400,000 square miles, 3,000,000 persons receiving relief. The drought of 1899 and the famine of 1900 affected South Punjab, Rajputana, Central India, Berar, Central Provinces, Hyderabad, Bombay Presidency and part of Orissa, Chota Nagpur, and Madras, an area of 600,000 to 700,000 square miles, and 6,500,000 persons required relief.

In discussing the meteorology of so large an area as India, it is impossible to detail all the local variations, but from among some examples given, Kilba, a station in the Simla district, may be mentioned. During the eleven years under discussion, Kilba for ten years received deficient rainfall, and instead of the normal 441·9 inches received 304·4 inches, the deficiency being equal to 3½ years' normal fall.

Using the data from 450 stations selected by the late Mr. Blandford as most trustworthy and representative, and giving due weight according to the area represented by each station, the average rainfall over India is given in inches:—1892, 46·18; 1893, 50·16; 1894, 47·56; 1895, 38·90; 1896, 36·26; 1897, 40·94; 1898, 41·52; 1899, 29·85; 1900, 40·52; 1901, 36·86; 1902, 39·04, the normal annual rainfall being 41·09 inches. The division of these years into a wet and a dry season is obvious.

On examining the amount of rainfall during the different seasons of the year, the fact is brought out clearly that all the seasons were affected by the abnormal conditions. During 1892–1894 all parts of the year had a tendency to excess rain. In 1893 the dry season had relatively more excess rain than the wet season. During the dry period 1895–1902 there was a tendency to deficiency of rain during all the seasons. Yet during a normal year the meteorological conditions which obtain during the wet season and the dry season are quite inverse of each other.

The persistence of the abnormalities through the seasons is also shown by the observations of cloud amount, humidity and temperature.

Discussing the geographical distribution of the rain, Sir John Eliot points out that during the wet period 1892–4 all parts of India received excess rain except in 1894, when the Bombay and Malabar district and the Madras district were deficient by 2 per cent. and 3 per cent. of the normal respectively. In 1892 the excess was more marked in those areas which received their south-west monsoon rain by the Bombay or Arabian Sea current, in 1893 and 1894 in those areas supplied by the Bay of Bengal current, and the excess was relatively greater in those areas which are near the interior limits of the fields of the two currents. The abnormal extension and strength of the monsoon currents are indicated by this excess in the interior.

During the period there was generally excess rain in

[1] "A Preliminary Investigation of the more Important Features of the Meteorology of Southern Asia, the Indian Ocean, and Neighbouring Countries during the Period 1892–1902." With Appendices. By Sir John Eliot, M.A., F.R.S., K.C.I.E. (Indian Meteorological Memoirs, vol. xvi. part ii.).

Baluchistan, Afghanistan, Persia, Zanzibar, and Mauritius, while the rainfall of Arabia, the Straits Settlements, and Port Blair was generally in defect. The defect at Port Blair is an illustration of the general rule that the rainfall of the Indian Sea area frequently varies inversely with that of the land area.

During the dry period 1895–1902 there was an almost continuous deficiency of rain over North Bombay, Central Provinces, Central India, and the Punjab. There was deficient rainfall for five years in Bengal, for four years in United Provinces and Madras, and for seven years in east and south Punjab. The interior districts suffered more than the coast, and those supplied by the Bombay current more than those supplied by the Bengal current. In 1899 the rainfall of North Bombay was 48 per cent. below the normal, and that of Rajputana and Central India 31 per cent. below. For five years out of eight these areas received at least 20 per cent. less rain than the normal.

The countries bordering on Indian area, and including Australia and South Africa, mostly suffered from want of rain.

During the wet period 1892–4 the monsoons were remarkable for the length of time over which they extended and for the persistence and steadiness of the monsoon conditions. In the dry period 1895–1902 the monsoons were generally characterised by their shortness. In 1896 and 1899, the years of drought, there was no prolonged delay in the commencement of the monsoon rains, but they stopped earlier than usual by three to seven weeks in the case of the Bombay current, and two to six weeks in the case of the Bengal current. This abrupt termination of the rains had a most disastrous effect upon the crops, especially in the Gangetic Plain and the Central Provinces. The crops dried and withered, and famine resulted.

The drought of 1896 was due in the United Provinces to scanty rainfall throughout the whole season, whereas in the Central Provinces and Berar it was due to the early termination of the rains. The year 1899 was characterised by the lack of heavy falls (*i.e.* falls of more than 3 inches in twenty-four hours) over all India, and especially so in the field of the Bombay current.

The data available show that the rainfall for all the countries which depend for their rain on the Indian Ocean was in excess during 1892–4, and in defect during 1895–1902. The rainfall over Russia, Turkestan, and Central Asia varied from the normal in the opposite manner.

The observations of cloud amount, relative and absolute humidity and temperature, show that the curves for these meteorological elements agree very closely with the curve for rainfall.

In discussing the variations of atmospheric pressure, Sir John Eliot refers to the important fact that the long-period variations as disclosed by barometric observations are similar in direction, amount and epoch over the whole of India, and gives both annual and monthly data showing this. Examination of the data giving the monthly variation of pressure from the normal shows that there were fairly long periods of continued excess or defect of pressure, that there was a decided oscillation of pressure. The period of oscillation is given as about two years. Sir Norman Lockyer and Dr. Lockyer, in a recent paper dealing with the rainfall of the Thames basin, refer to the annual pressure variation at Bombay, and speak of a 3·8-year period. Sir John Eliot gives a table showing the approximate dates of the changes from excess pressure and *vice versâ,* and notes that these changes almost invariably occur about the time of the change of season.

If these oscillations were due to exchange of air between the Indian Ocean and southern Asia, such as might accompany the seasonal changes, then the oscillations of pressure over these areas would be of similar period, but of opposite phase; but comparison of the Indian data with data from East Indies, China, South Africa, and Australia shows that this was not generally the case during 1895–1902. In 1893, when there was a deficiency of pressure recorded at Batavia, Singapore, Cape Town, Perth, and Adelaide, there was excess of pressure at Mauritius, Zanzibar, Hong Kong, and Zika Wei, and over India, but in other years, notably 1896, 1898, and 1899, there was a general agreement over the whole Indian Oceanic area and southern Asia. According to Sir John Eliot, this was not the case previous to the period under discussion. He says (p. 273):—" It was shown in the memoir [1] that the pressure variation at Mauritius from 1877 to 1889 presented long period oscillations or variations of similar period but opposite phases to the pressure variations in India," and also (p. 276) " the usual relation based upon previous investigations is for the pressure variations in Southern Asia to be of opposite character or sign to those of the Indian Oceanic region." Therefore he concludes that there was some great and abnormal movement of air affecting the barometric pressure over half the eastern hemisphere, but he has no data available to show the region where the opposite variation has taken place.

Sir Norman Lockyer and Dr. Lockyer, in their paper [2] on " The Similarity of the Short Period Pressure Variations over Large Areas," refer to a set of curves representing the pressure variations in Bombay, Colombo, Batavia, Mauritius, Perth, Adelaide, and Sydney, saying " the striking similarity between these curves shows that over the whole of this area, which includes both north and south latitudes, the same kind of variations is in action, and that therefore the whole region is intimately connected meteorologically."

These curves refer to the period 1874 to 1901. Attention might be directed to the fact that the term " long-period " seems to be applied by Sir John Eliot to variations which, when discussed by Sir Norman Lockyer, are called " short-period."

In another paper [3] by Sir Norman Lockyer and Dr. Lockyer two pressure curves are given, one for Bombay and one for Cordoba (Argentine), which are referred to thus:—" Dealing with the pressure of Cordoba during the high pressure months April to September, the curve representing the variation from the mean from year to year is exactly the inverse of the curve representing the Bombay and other Indian pressures for the same months over the same period of time. The cause therefore which raises the mean value for the low pressure months over the Indian area would appear to lower the mean value of high pressure months at Cordoba simultaneously. In fact we have a see-saw."

In a further paper [4] by the same authors, the surface of the globe is divided into two areas, one having the pressure variations of the Indian type and the other those of the Cordoba type.

These quotations show that there is evidently a difference of opinion on the question of the similarity or dissimilarity of the pressure conditions of Southern Asia, Australia, and Africa previous to the year 1892; and it is quite possible that the meteorology of these regions during the period, 1892–1902, was not so abnormal as Sir J. Eliot suggests.

From a discussion of the observations of variation of solar radiation, as indicated by the black bulb thermometer, Sir J. Eliot states that the data indicate that during 1891 to 1896 or 1897 there was an excess of solar radiant energy, and during 1898–1902 there was defect.

As such a defect would diminish the supply of aqueous vapour, and consequently the rainfall, accurate observations of the variations in solar radiation should give an explanation of the variations of the rainfall and air pressure. Observations by means of the black bulb solar radiation thermometers are, however, not considered very satisfactory.

Appendices to this important memoir give extracts from various official reports on the famines of 1897 and 1900 containing information with regard to the damage to crops and cattle. A large amount of data is also given referring to seasonal rainfall, rainy days, pressure, and dates of commencement and termination of the monsoon rains during the period discussed. Twenty-one plates of curves relating to the same observations form a not unimportant part of the volume which they conclude. W. M.

PHYSIOLOGY AT THE BRITISH ASSOCIATION.

THE section of physiology concerned itself very largely with the consideration of questions which are of practical importance to workers in South Africa at the present time. Such diseases as scurvy, leprosy, and plague offer problems which demand instant consideration, and in some cases legislation. The treatment of these maladies formed the subject-matter of papers by the medical officer for Cape Colony and his staff.

The diseases of cattle are at present of great importance in South Africa; they played a prominent part in the proceedings, both at Cape Town and at Johannesburg. The fate of the four colonies, but especially of Rhodesia, is intimately bound up with their value for rearing horses, cattle, sheep, and goats. In recent years, and more especially since the importation of stock from all parts of the world during and after the Transvaal war, several forms of disease have attacked the domestic animals of South Africa. The severity of these diseases may be judged from the fact that 97 per cent. of the horses at Umtali died of horse-sickness in a recent epidemic. No more pressing problems, therefore, than the cause and prevention of stock diseases present themselves to the students of pathology in South Africa. At Cape Town the morning of August 17 was devoted to their consideration. Two important communications were given by Mr. Hutcheon, principal veterinary surgeon for Cape Colony, and Mr. Lounsbury, Government entomologist in Cape Colony. Mr. Hutcheon's great experience of the subject, extending as it does from a time when the parasitic nature of these diseases was unknown, and his constant and successful efforts to combat successive devastations, render his communication especially valuable. In recent years Mr. Lounsbury also has done a vast amount of first-class work in connection with the habits and life-history of the various forms of tick which act as intermediate hosts for the piroplasmic organisms. At Johannesburg a very comprehensive paper on rinderpest was given by the Hon. George Turner, and one of much interest on horse-sickness and similar maladies by Dr. Theiler, principal veterinary surgeon of the Transvaal. Colonel Bruce's presidential address dealt also with stock diseases.

The importance of South Africa as a health resort occupied the entire sitting of August 16. Sir Lauder Brunton opened a discussion upon the effect of climate upon disease and upon health. Dr. Gregory and other South African medical officials took part in this discussion. Results also of great scientific interest upon the effect of high altitudes on health were given by Prof. Bohr, of Copenhagen. Mr. Barcroft described the outcome of recent researches upon the production of heat in the individual organs of the body, and indicated the bearing of these investigations upon the heat-formation of the body under varying climatic and dietetic conditions.

The morning of September 1 was devoted to purely physiological topics.

Some of the more important communications may be summarised as follows:—

August 16.—Discussion on the effect of climate upon health. Sir T. Lauder Brunton, F.R.S., pointed out that three primary points had to be thought of in considering climate, its effect (1) on the human body; (2) on the organisms which give rise to disease; (3) on the carriers of disease. After a detailed investigation of the effects of change of environment upon protoplasm, he showed that for every cell there was an optimum degree of humidity and of salinity; but more important than these was the optimum temperature. When the temperature of the body fell below 98°·4, the vitality, not only of muscle, but of every other tissue, became reduced. The amount of heat produced depended upon the activity of the tissues; the loss of heat largely depended upon the environment (especially the temperature and the humidity). The nature of the soil greatly affected the humidity, but often pathological conditions were put down to the climate which were attributable in reality to the effect of the geological structure of a locality upon its water supply; for instance, the constipation experienced by many persons at sea-side resorts in the south of England was not due, as often supposed, to the sea air, but to the calcareous water. Electrical conditions were referred to, especially the observations of Wier Mitchell and Dexter in America.

Dr. Gregory pointed to the prevalence of tuberculosis in South Africa, of which 17 per thousand of the natives and 7 per thousand of the white population died annually. On the other hand, scarlatina, small-pox, typhoid, and influenza existed in much milder forms than in Europe.

Prof. Bohr, speaking of the effect of high altitudes upon health, introduced the results of his most recent investigations upon the invasion and evasion coefficients of oxygen in contact with liquid surfaces, and used these coefficients to calculate the minimum barometric pressure which was consistent with adequate respiration. He showed how compensation was carried out at low pressures, which, however, were higher than the absolute possible minimum. The full account of his investigations appears in Nagel's "Text-book of Physiology"—article on respiration—to which the reader is referred.

Mr. Barcroft dealt with the heat production in the organs of secretion and excretion, and showed that these organs were responsible for a much greater share of the heat produced in the body than was formerly supposed. The following figures might be taken as representing our present knowledge of the heat formation per gram per minute of certain organs when at rest:—The submaxillary gland, 0·2 calories; the kidney, 0·15 calories; skeletal muscle, 0·02 calories. In climates, therefore, where the opportunity for heat loss was small (*e.g.* hot-damp climates) these organs should not be unduly taxed.

Other speakers were Dr. A. J. Mitchell, Prof. Sims Woodhead, Dr. Murray, and Prof. Halliburton, F.R.S.

August 17.—Mr. Hutcheon, principal veterinary surgeon, gave an historical account of the diseases which had devastated the stock of South Africa—pleuropneumonia, redwater, rinderpest, east coast fever, biliary fever, horse-sickness, &c. Of these, heartwater, rinderpest, and horse-sickness were the results of ultramicroscopic blood-parasites, whilst the redwater of cattle and the east coast fever were definite piroplasmic diseases. Ticks were responsible for the communication of heartwater, redwater, and east coast fever; horse-sickness was probably communicated by a mosquito. Mr. Hutcheon went fully into the means that were now taken for preventing these diseases. In the cases of redwater, heartwater, and rinderpest inoculation had been successfully carried out.

Mr. Hutcheon attributed the absence of horses in South Africa to the fact that zebras took horse-sickness, but not fatally, and thus the infection was kept alive.

Mr. Chas. P. Lounsbury, Government entomologist for Cape Colony, treated of ticks as a means of transmission of disease. The main features in the economy of ticks were first discussed. *Amblyomma hebraeum* is the tick responsible for conducting the heartwater of goats, sheep, and cattle. It therefore prevents the successful farming of wooled sheep and Angora goats over a considerable tract of the country. The tick becomes infected at one stage of its life-cycle and communicates the disease at another. The requisite condition of warmth is necessary during the metamorphosis of the tick if the disease is to be communicated. Sheep of the Persian breed take the disease more mildly than other varieties, and the virus is somewhat modified by passing through them. The progeny of the transmitting tick appears to be innocuous. *Haemophysalis leachi* is responsible for the communication of canine piroplasmosis. Unlike *Amblyomma hebraeum*, this tick only communicates the virus by means of adults which are the progeny of infected females. The virus, therefore, passes through the egg, and remains latent in the nymphal and larval stages.

African east coast fever is communicated, like heartwater, by the nymphs or adults of ticks which have themselves fed upon a sick animal. Five species of the genus Eurhipicephalus, viz. appendiculatus, nitens, evertsi, simus, and capensis, have been proved to carry this disease.

Other speakers in this discussion were Colonel Bruce, F.R.S., Sir W. Hely-Hutchinson, Mr. Robertson, Prof. Sims Woodhead, and Mr. Bowhill.

August 18.—Dr. Gregory gave a comprehensive paper recounting the deductions which he had been able to make touching the nature of scurvy as it exists in South Africa.

His main thesis was that the scurvy of South Africa is infectious in its nature, and probably of bacterial origin. It is subject to seasonal variation; it occurs in epidemics which vary in the intensity of their virulence. Its incidence is greatest amongst the native races, and it has a very high percentage of recurrences. An anti-scorbutic diet does not prevent it. It occurs where the diet contains a plentiful supply of fish and vegetables, and does not necessarily occur where these foodstuffs are deficient.

Dr. Mitchell gave a detailed history of the plague epidemics in Cape Colony. He showed that the plague in every case was introduced by rodents, and suggested more stringent measures to prevent the introduction of infected animals.

Dr. R. S. Black, formerly physician to the leper asylum at Robben Island, gave an account of leprosy in South Africa. He dwelt on the accumulation of evidence which existed in favour of leprosy being an infectious disease, and the absence of any data which had come under his notice in favour of this disease being due to the eating of fish. In the discussion which followed the paper Prof. Sims Woodhead pointed out the importance to patients themselves, and to the State, of removing any ambiguity as to the infectious nature of leprosy. It could not be too clearly understood by the native population that the policy of segregation was not prompted by one of a number of rival theories, but was the result of established facts.

On August 19 some of those who had attended the section enjoyed the hospitality of the Cape Government at Robben Island, where they were shown the admirable arrangements for treating the lepers.

Johannesburg, August 29.—The proceedings of the section opened with the president's address. This has been printed *in extenso* in the columns of NATURE; it is therefore unnecessary to refer to it here further than to say that it struck the key-note of the whole work of the day's sitting. Colonel Bruce dealt very fully with the stock diseases of South Africa from the purely scientific side. Those whose papers followed (the Hon. George Turner and Dr. Theiler) dealt with rinderpest and other stock diseases from the point of view of the practical student of the problems which these diseases offered to the farmers and to the executive of the Transvaal. The urgency of the situation which was caused by the rinderpest epidemics and the success of the means which were used to cope with them are shown, as Mr. Turner pointed out, by the fact that 986,518 animals are estimated to have been saved by inoculation. Roughly, four thousand five hundred litres of serum have been used for the inoculation at a cost of 7*l.* 10*s.* per litre. In some herds the method of "simultaneous injection" of virulent blood and immunising serum has been so successful that only 14 per cent. of the cattle have fallen victims to the epidemic, whilst 1·3 per cent. have been killed by the injection.

Dr. Theiler's paper dealt with stock diseases generally; the fact, however, that his name is so intimately connected with recent advances of knowledge into the etiology and prevention of horse-sickness accentuated the interest of that part of his communication which dealt with this disease. Briefly summarised, horse-sickness especially occurs in low-lying districts during the rainy season. Animals are infected only at night. The infection ceases as soon as the frost comes. The disease is inoculable in animals of the same species, but is not contagious. Horse-sickness is distinct from "blaau tongue" or catarrhal fever, which closely resembles it in most of the above characteristics. The virus of horse-sickness is easily destroyed by desiccation, but it is not affected by cold. Both the above diseases are conveyed from animal to animal by insects. Veterinary Surgeon Spreuill has succeeded, by hyperimmunising sheep with virulent blood, in producing a serum which is efficacious in cases of "blaau tongue." The author has achieved immunity against horse-sickness in mules and horses by simultaneous subcutaneous injection of serum and intravenous injection of virus.

August 30.—An interesting feature of the work of the section, and one for which it is much indebted to the officials, was a visit to the compound hospital, presided over by Drs. Louis G. Irvine and Donald Macaulay. As an introduction to the inspection, a paper was communicated by Dr. Macaulay and Dr. Irvine upon the conditions of native labour in the mines. They pointed out the great difficulty of persuading the native workers to care for their own health, to take even the simplest precautions, for instance, on coming up from the deep mining levels into the cold air. The death-rate was much lower than formerly, but it was still very high as the result of pneumonia and phthisis. The main problem, however, is that of acclimatisation.

Other papers were read by Dr. Leingme on diseases of natives, Dr. Maberley on the pharmacology of South African drugs, and Prof. McKendrick, F.R.S., on the effect of radium on the electric currents of the retina.

September 1.—Prof. Waller, F.R.S., gave an account of his recent researches into the means of estimating the percentage of chloroform vapour in air by means of the densimeter. He showed how frequently the cause of death was due, not to idiosyncrasy of the patient, but to an unsuspected increase in the dose of chloroform. This might occur whatever method was used, but it was specially likely to happen when the so-called "Edinburgh method" of administration with a towel was used. His experiments had shown in theory what had already been proved by practice, namely, that a mask covered with donette delivered the proper percentage of chloroform to the patient, namely, 2 per cent.

Dr. Pavy, F.R.S., read a paper for which the thanks of the section are due to him in an unusually large measure. The main thesis was based upon Dr. Pavy's well known view that the comparatively small molecules into which the food is broken down in the intestine do not exist in the blood as such. This view is the result of so much practical experience of the treatment of diabetes and of so much careful thought and accurate work that it must always command the respect of physiologists if not their adherence. The part of Dr. Pavy's paper dealing with the mechanism which exists for building up such molecules as sugar into the larger molecules of which they form but a small part was of a much more speculative nature. The author's view was that this function was performed by the lymphocytes, which took up sugar, &c., much as hæmoglobin acquires oxygen. The sugar is thus built up into the molecules of living protoplasm, and is subsequently imparted to the plasma and indirectly to the body.

Dr. M. Armand Ruffer gave a brief account of the evolution of the present knowledge of immunity artificially acquired. His own researches show that the serum of rabbits injected with human, bovine, or ovine urine dissolves *in vitro* the red blood corpuscles of that species of animals the urine of which has been injected. It is specific, *i.e.* has no action on the red blood corpuscles of any other species of animals. The author calls lysogen the substance which, when injected, produces a hæmolytic serum. Lysogen dialyses slowly, is not precipitated completely by alcohol, but wholly by saturation with ammonium sulphate or lead acetate. Simple exposure to air for one month or more destroys it, though it resists putrefaction and is not wholly destroyed by a temperature of 100° C. Urine contains hæmosozin or hæmosozins, *i.e.* a substance or substances preventing the action of hæmolytic serum. Some urines, *e.g.* human urine, prevent the action of serum dissolving human, bovine, and ovine red blood corpuscles; others, *e.g.* bovine urine, act only on a serum dissolving bovine red blood corpuscles. Dialysed urine is just as active as ordinary urine. Hæmosozin has practically the same physical and chemical characteristics as lysogen. Bile contains at least two groups of hæmolysins, and at least one hæmosozin. This hæmosozin is specific, *i.e.* prevents the hæmolytic action of the bile of that species of animals from which the hæmosozin was extracted, but not the biliary hæmolysins of any other species of animals.

The paper concluded by pointing out the necessity of making sera with isolated substances, and not with the crude products of bacteria. By injecting crude products it is more or less a matter of chance what the properties of the serum will be.

The proceedings ended at Johannesburg, as they had done at Cape Town, with an expression of thanks to the local officials of the section who had taken infinite pains to bring the meetings up to the high level of interest which they attained.

J. BARCROFT.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—This week twelve of the larger colleges are holding their entrance scholarship examinations. They are divided into two groups of five and seven colleges respectively. Judging from the number of candidates, which is larger than ever before, there is an unprecedented desire amongst schoolboys to share in the endowments of Cambridge.

The annual dinner of the Cambridge Philosophical Society will take place on Saturday, December 9. It will be held in the hall of Christ's College, and Prof. Marshall Ward will be in the chair.

The regulations for the diploma in mining engineering have been published in the *Reporter* by the special board for physics and chemistry, together with the schedules of the proposed examinations.

The general board of studies has approved Dr. W. L. H. Duckworth, of Jesus College, for the degree of Sc.D.

The special board for biology and geology has adjudged the Walsingham medal for 1905 to Mr. W. S. Perrin, of Gonville and Caius College.

THE new buildings of the Glasgow and West of Scotland Technical College, which when completed will be the largest of the kind in Great Britain, are to be opened by the Marquess of Linlithgow, Secretary for Scotland, on December 21.

WE learn from *Science* that by the will of the late Mr. Joseph E. Gillingham, numerous bequests are made to educational institutions, including 10,000*l*. each to the University of Pennsylvania for the veterinary department, to Haverford College, to Swarthmore College, and to Bryn Mawr College.

THE *British Medical Journal* announces that Prof. Czerny has resigned the chair of surgery in the University of Heidelberg, which he has held since 1877, in order to devote himself entirely to the duties of director of the Institute of Cancer Research. He will be succeeded in the chair of surgery by Prof. Garré, who accepted a call to Breslau after the death of Prof. von Mikulicz.

A FEW months ago Sir Donald Currie offered a sum of 20,000*l*. to Queen's College, Belfast, provided a like sum was contributed by the friends of the college before the end of the present month. The sum of 3000*l*. was required to complete this contribution, and this has now been subscribed by Sir Otto Jaffe, chairman of the executive committee of the better equipment fund of Queen's College. The college will therefore now receive 40,000*l*. toward its better equipment.

AT the annual meeting of the court of Liverpool University on November 30, the Pro-Chancellor announced that the university would shortly receive from the executors of the late Mr. J. L. Bowes, of Liverpool, a sum of about 8000*l*., to be divided between the departments of modern languages and chemistry. A resolution was adopted to the effect that the decision of the court as to the formation of a school of military instruction be deferred until the court is in possession of fuller information as to the need of such a proposed school, and that meanwhile the council be requested to take no further steps towards its establishment.

THE new techno-chemical institute of the Charlottenburg Technical High School was opened on November 25 in the presence of a distinguished scientific audience, which included the Imperial Minister of Education, Dr. Studt, accompanied by Geh. Rat. Naumann and Freiherr von Thielmann, Profs. Emil Fischer, van 't Hoff, Landolt, Nernst, Beckmann, Will, von Knorre, Liebermann, and the following representatives of chemical industries:—Prof. Duisberg, Prof. Lepsius, Dr. Oppenheim, Dr. Knietsch, Dr. von Martius, Dr. Kunheim Kommerzienrat Brunck, Messrs. Birkeland, Eyde, Pettersson, and others. The new institute is a fine five-storeyed building, excellently equipped with the best of modern chemical laboratory arrangements and apparatus. The director, Prof. Dr. O. N. Witt, in his opening address, after dwelling upon the history and the aim of this, the newest addition to the Charlottenburg High School, detailed Birkeland and Eyde's method for the fixation of atmospheric nitrogen, and illustrated his account by an experiment carried out on a large scale. After the address the Educational Minister, Dr. Studt, decorated Prof. Witt with the Order of the Red Eagle, third class, and the architect, Dr. Körber, with the Order of the Red Eagle, fourth class.

A DEPUTATION from colleges connected with the teaching of agriculture who desired additional grants for research and higher education in agricultural science from the Imperial Exchequer was received by Sir Thomas Elliott at the Board of Agriculture on Tuesday. Sir Isambard Owen, the principal of the Armstrong College, Newcastle-upon-Tyne, stated the case on behalf of the deputation. It was urged that higher agricultural education was a public necessity, the cost of which could not be reasonably expected to be met in a very large proportion from local sources, and that they were amply justified in asking for State assistance. Sir Thomas Elliott, in reply, said that the Treasury had not hitherto met the demands of agriculturists illiberally altogether. Fifteen years ago the grant was 4500*l*., and now it was 10,550*l*. Of course, it was difficult to get increased local contributions owing to the increase of educational burdens upon local authorities. He quite agreed with the deputation that there was great room for the development of scientific research. There were great problems to be solved of an economic character which would produce results far beyond the cost of investigation or experiments. He thought the time had come for the coordination of the various agencies for agricultural research in this country. The Board had the fullest sympathy with the work which the colleges had done, and he hoped it would be able in some measure to meet their aspirations.

AT the winter session last week the General Medical Council considered the report of the education committee on the question whether the adoption of the following resolutions would not help to secure the attainment of the object which the council had in view in instituting the five years' curriculum:—"(1) That the preliminary scientific examination in physics, biology, and chemistry should be passed before the student begins the qualifying study of anatomy and physiology; (2) that before being admitted to the final examination the student should produce evidence that he has devoted the last year of his curriculum exclusively to practical and clinical work and study." The committee reported that the main effect of the proposed change would be seriously to lengthen the curriculum and thus to render entrance to the profession more difficult and expensive. At present the curriculum is far more often one of six or even more years—and this even in the case of industrious students—than one of five. With regard to the second resolution, the committee held that distinct evidence of clinical and practical study in the fifth year should be produced by the student, showing that his time in that period of his curriculum had been mainly occupied in such work, but they would not suggest any regulation which should absolutely limit the work of each session of the period of professional study. Dissatisfaction was, however, expressed with the committee's report, and the subject is to be re-considered. The two following questions were referred to the education committee to be investigated and reported upon:—(1) As to the desirability of transferring the preliminary science subjects of physics, biology, and chemistry from the curriculum of medical studies to a stage preliminary to the commencement of the curriculum; and (2) as to the advisability of requiring a five years' period of study, even after removing from the curriculum these preliminary science subjects.

THE report of the Board of Education for the year 1904–5 has now been published. After a general review of the work of the Board, detailed particulars of the following classes of schools are given in order:—public elementary schools, secondary schools and technical institutions, evening schools and schools of art. In the section dealing with secondary schools, the report lays it down that, "although it would be inexpedient and unjust to withdraw approval, and the support hitherto given, from those schools which have already been organised with a curriculum which is specialised from the first on the side of applied science, if

it can be shown that such a course is suitable to the circumstances of the locality in which the school is placed, yet it is not the intention of the Board to sanction the adoption of this special course in any fresh school." This decision is a little difficult to understand. If it can be shown at present that some schools, in which science takes a specially prominent part, are suitable to the locality in which the school is placed, it would appear reasonable to suppose that other localities in the future may demonstrate the need for a precisely similar type of school, and yet the Board has decided beforehand that—such demonstration notwithstanding—there shall be no more such schools. Experience has shown that the so-called "school of science" is capable of supplying just the training boys from elementary schools in manufacturing centres require to prepare them for their work in life, and it is to be hoped in these cases that every encouragement will be given to a definite course of study in science in the schools. All educationists of experience agree with the Board's opinion, expressed in subsequent paragraphs of the report, that premature specialisation in the work of ordinary secondary schools is to be discouraged, and that a well balanced curriculum, comprising literary and practical subjects taught in a scientific manner, is of prime importance; but such agreement does not preclude the possibility of applying special remedies to special needs. It is satisfactory to find that the report contains abundant evidence of a continued improvement in the work of secondary schools and technical institutions.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 16.—"The Transit of Ions in the Electric Arc." By A. A. Campbell **Swinton.** Communicated by the Hon. C. A. Parsons, C.B., F.R.S.

The paper describes an experiment designed to show that in the electric arc the positive and negative electrodes emit carriers or ions which are respectively positively and negatively charged, and, after travelling across the arc, bombard the opposite electrode. The method adopted resembles that employed by Perrin to prove the negative charge carried by kathode rays. A small hole was pierced axially through one of the carbon electrodes, and immediately behind this aperture was fixed an insulated Faraday cylinder of brass which had its aperture in line with, and facing the aperture in, the electrode. A galvanometer connecting the insulated cylinder and the pierced electrode measured any difference of potential between the two. The second electrode was an ordinary carbon pencil, and as this was made positive or negative it was found that positive or negative charges respectively were communicated to the insulated Faraday cylinder, provided the arc covered the aperture in the pierced electrode, but not otherwise. These results, which confirm the theory as enunciated above, were obtained both in air at atmospheric pressure and also *in vacuo* up to what could be obtained with a mechanical air pump. The galvanometer deflections increased considerably with the degree of exhaustion, and at any given degree a much larger deflection was obtained when the second electrode was made negative and the cylinder was being charged negatively than when the contrary was the case, this corresponding with the known fact that negative ions have a higher velocity than have positive ions.

Geological Society, November 8.—Dr. J. E. Marr, F.R.S., president, in the chair.—The coast-ledges in the south-west of the Cape Colony: Prof. E. H. L. **Schwarz.** The author compares the shelves of Cape Colony with those described on the European and American sides of the North Atlantic, and he places the "absolute base-level of erosion" at 12,000 feet in North America, 8000 feet in Europe, and 1200 feet in South Africa. With these varying heights he correlates the topography of the bordering continents—the sharp divides, open river-valleys, permanent rivers and deltas, of Europe and America, where the movement has been downward and has almost reached bottom, in contrast with the flat undenuded divides, the steep, narrow gorges, the waterfalls, and the rocky river-gates, of South Africa, which is on the upgrade and probably near the top.—The Glacial period in Aberdeenshire and the southern border of the Moray Firth: T. F. **Jamieson.** One of the most interesting features in the glacial geology of Aberdeenshire is the Red Clay found along the eastern coast of the county. The purer masses of clay seem to have formed in a sheet of water lying in front of the ice, between it and the land, during the retreat of the Aberdeenshire ice, and at a time when the coast was submerged beneath water to a level exceeding 300 feet above the present coast-line. Evidence of the northward motion of the ice is given from striæ, the transport and removal of flints, and the bending-over of the edges of folia of gneiss. The Red Clay is underlain by a Grey Clay, and sometimes covered by a similar one. The author has recently discovered remains of a still older, dark indigo in colour, and containing small fragments of sea-shells. On the southern border of the Moray Firth the author gives examples of glacial marking on the rocks, and refers to the transport of boulders, including a huge mass of Oolitic rocks 40 feet thick, a mass of clay once considered to be an outlier of Lias, "pipe-rock," and the fossiliferous Greensand débris at Moreseat, now considered to have been transported by ice.

November 22.—Dr. J. E. Marr, F.R.S., president, in the chair.—On a new specimen of the chimæroid fish *Myriacanthus paradoxus*, Ag., from the Lower Lias of Lyme Regis (Dorset): Dr. A. S. **Woodward.** The author, having proved that the dorsal fin-spine of the so-called *Ischyodus othorhinus* is identical with an ichthyodorulite which has been named *Myriacanthus granulatus*, inferred that the larger ichthyodorulite *M. paradoxus* belonged to the same fish as the larger dentition named *Prognathodus Guentheri* by Egerton. This question has been settled by the discovery by Mr. S. Curtis, in the Lower Lias of Black Ven, of a dorsal fin-spine in direct connection with a mass of decayed cartilage, dermal plates, and teeth. The new fossil warrants the conclusion that Myriacanthus is a chimæroid, closely similar to the Upper Jurassic Chimæropsis, with (1) a median chisel-shaped tooth in front of the lower jaw; (2) a few tuberculated dermal plates on the head; and (3) a tuberculated dorsal fin-spine. In these respects it differs from all other known chimæroids—even from the comparatively primitive types which have been discovered during recent years in the Japanese seas. The Myriacanthidæ, in fact, have still no nearer ally than Callorhynchus, with which Egerton originally compared his so-called *Ischyodus orthorhinus*.—The rocks of the cataracts of the River Madeira and the adjoining portions of the Beni and Mamoré: Dr. J. W. **Evans.** The crystalline rocks of the cataracts of the River Madeira and the lower waters of its tributaries are part of a ridge with a north-westerly and south-easterly strike, similar to that of the Andes in the same latitudes. This strike is especially prevalent in equatorial regions. With the exception of comparatively recent alluvial deposits and a few pebbles of chert, pronounced by Dr. G. J. Hinde to be of marine origin, but uncertain date, only crystalline rocks are met with in the falls. They all appear to be igneous, and are mostly massive in character, though some dyke-rocks occur. In places they are typical gneisses, and they are often banded, but in some cases they show no signs of foliation. The prevailing type is acid, with a considerable proportion of alkalies, especially soda; but some of the rocks are distinctly basic in character.—The Doncaster earthquake of April 23, 1905: Dr. Charles **Davison.** The Doncaster earthquake of 1905 was a twin, with its principal epicentre half a mile north of Bawtry, and the other about 4 miles east of Crowle and close to the centre of the disturbed area of the Hessle earthquake of April 13, 1902. The distance between the two epicentres is about 17 miles. The disturbed area contains about 17,000 square miles, including the whole of the counties of Lincoln, Nottingham, Derby, Stafford, Leicester, and Rutland, the greater part of Yorkshire, and portions of Lancashire, Cheshire, Shropshire, Worcestershire, Warwickshire, Northamptonshire, Cambridgeshire, and Norfolk. The originating fault runs from about E. 38° N. to W. 38° S., and appears to be nearly vertical within the south-western focus and inclined to the south-east in the north-eastern focus. The first and stronger movement took place within the south-western focus. A twin-earthquake

is probably due to the differential growth of a crust-fold along a fault which intersects it transversely, the first movement, as a rule, being one of rotation of the middle limb, accompanied by the almost simultaneous slip of the two arches, and followed soon afterwards by a shift of the middle limb.

Zoological Society, November 14.—Mr. G. A. Boulenger, F.R.S., vice-president, in the chair.—*Exhibitions.*—(1) The mounted head and skin of a white water-buck (*Kobus ellipsiprymnus*) from British East Africa; (2) two mounted heads of the rhinoceros, one of which showed abnormal growth of the anterior horn, whilst the other bore four horns, viz. two on the nose, one between the ears, and one nearly at the back of the head: Colonel W. H. **Broun.**—(1) Specimens of a very rare and interesting marsupial, hitherto unique, in the Paris Museum, viz. *Dactylopsila palpator*, Milne-Edw., which differed from *D. trivirgata* by the extremely thin prolonged second finger; (2) two tusks which had been obtained by Baron Maurice de Rothschild during his recent expedition to Abyssinia: Hon. W. **Rothschild.**—Microscopic preparations of a new hæmosporidian from the blood of an African stork (*Leptoptilus crumeniferus*): A. S. **Hurst.** The exhibitor pointed out that this parasite belonged to the genus Halteridium, but differed from *H. danilewskyi* in its greater size (stade moyen 7–10 μ), and also in its method of sporulation, in which the merozoites were more numerous, smaller, and arranged in a ball-like rounded mass. The name *Halteridium crumenium* was proposed for the new species.—A letter from Mr. William Rodier, of Tambua Station, Cobar, N.S.W., concerning the continued success of Mr. Rodier's plan for counteracting the rabbit pest: Dr. P. L. **Sclater.** The plan consisted simply in catching the rabbits alive and killing the females only, letting the males go free.—The *Satyrus indicus* of Tulpius, said to be the type of the genus Simia: H. **Scherren.** Remarks were made with the view of showing that the animal was a gorilla, and was recognised before the middle of the eighteenth century as differing from a chimpanzee. The distinction between the *tschego* and the *ngina* was, he said, known in England in the first quarter of the nineteenth century.—*Papers.*—On the papillary ridges in mammals, chiefly primates: Dr. W. **Kidd.** The arrangements of the ridges on the hand and foot of twenty-four species were shown and described, and their functions discussed. Arguments were brought forward to show that their primary function was to increase the delicacy of the sense of touch. On the mammals brought back by the Tibet Mission: J. L. **Bonhote.** The collection was very small, containing examples of only some eight species, three of which were described as new, viz.:—(1) *Vulpes vulpes waddelli*, subsp.n. Similar to *V. v. flavescens*, but the whole coloration much brighter, especially the median dorsal area, which was deep red and markedly distinct from the colour of the flanks. (2) *Cricetulus lama*, sp.n. Allied to *C. phaeus*, but much greyer in general coloration, and the tail somewhat longer and stouter. (3) *Microtus* (*Phaeomys*) *waltoni*, sp.n. Closely allied in skull characters to *Ph. blythi*. The general coloration, however, was fulvous-grey, slightly greyer over the anterior part of the body.—Notes on the geographical distribution of the okapi: Dr. E. **Lönnberg.**—Observations on the Goral (*Cemas goral*) in Burma: Major G. F. **Evans.**—A collection of the mammals of Crete: Miss D. M. A. **Bate.** Examples of sixteen forms, of which six were described as new subspecies, were contained in the collection, and these were enumerated and remarked upon in the paper.

Physical Society, November 24.—Prof. J. H. Poynting, F.R.S., president, in the chair.—The dielectric strength of air: A. **Russell.** The author makes the assumption that for distances apart greater than about a millimetre when the disruptive voltage is V kilovolts the effective P.D. between the ends of the Faraday tube which is subject to the maximum stress is $V-\epsilon$, where ϵ is the minimum sparking voltage. Applying formulæ which he has deduced, using this assumption, to tests of Heydweiller, Steinmetz, Algermissen, &c., the author finds that they agree in making the dielectric strength of air 38 kilovolts per cm. approximately. A knowledge of this quantity enables us to find, not only the disruptive voltages between electrodes of many geometrical shapes, but it also enables us to find the "critical" pressure for overhead electric-power transmission at high pressures.—On the electrical conductivity of flames for rapidly alternating currents: Dr. H. A. **Wilson** and E. **Gold.** The following is a summary of the results:—(1) For rapidly alternating currents a flame containing an alkali salt vapour behaves like an insulating medium of high specific inductive capacity. (2) The conductivity of different alkali-salt vapours in a flame for rapidly alternating currents, as measured by the apparent capacity of platinum electrodes immersed in the flame, varies as the square root of the conductivity of the same salt vapours for steady currents. This result confirms the view that the negative ions from all salts have the same velocity. (3) The apparent capacity varies nearly inversely as the square root of the maximum applied P.D. (4) The apparent capacity is nearly independent of the number of alternations per second. (5) The apparent capacity is nearly independent of the distance between the electrodes. (6) The results (1) to (5) are in agreement with the ionic theory of the conductivity of the flame for rapidly alternating currents when the velocity of the positive ions and the inertia and viscous resistance to the motion of the negative ions are neglected in comparison with the effects due to the number of ions per c.c. (7) The apparent capacity per sq. cm. area of the electrodes is equal to $\sqrt{ne/8\pi V_0}$, where n is the number of positive ions per c.c., e the charge on one ion, and V_0 the maximum applied P.D. (8) Not more than one molecule in ten of salt molecules is ionised at any instant, but each molecule is probably ionised and re-combines several million times per second. (9) The steady currents observed through salt vapours in flames are very far from the maximum possible currents corresponding to the number of ions produced per second.—On the lateral vibrations of loaded and unloaded bars: J. **Morrow.** This is a continuation of the work previously communicated by the author on the vibration of bars of uniform and varying sectional area. By means of a method of continuous approximation the elastic displacement curves and the frequency of the lateral vibrations of bars can be determined to any required degree of accuracy. The method is first applied to some cases of unloaded bars, and also to massless bars carrying concentrated loads. The paper then deals with the principal problems of loaded bars which are themselves of appreciable mass.

MANCHESTER.

Literary and Philosophical Society, October 31.—Prof. W. Boyd-Dawkins, F.R.S., vice-president, in the chair.—On a biological aspect of cancer: F. J. **Faraday.** The author directed attention to a paper with this title read by him in 1899, and printed in vol. xliii. of the society's *Memoirs*. Several of the conclusions recently arrived at by the cancer research committee were therein foreshadowed, *e.g.* that cancer is not a microbic disease, but is due to an arrest of development and differentiation among the somatic cells, growth being restricted to mere gemmation.—Some recent researches into the nutrition of the egg cell in certain plants: Dr. Marie C. **Stopes.** The special group of plants on which the author worked was that including the pine trees, Ginkgo, and the Cycads, viz. the Gymnosperms. Though the egg cells in this group are in many ways different from those of the flowering plants, the results have some bearing on the question of nutrition of egg cells in general, as well as some points of general technique. Much of the work was done in conjunction with Prof. Fujii, of Tokio, with whom the author is publishing a joint paper on the subject in Germany.—A model to illustrate the propagation of sound waves: Dr. H. **Ramsden.** The model consists of a series of magnetised needles, suspended vertically so as to vibrate in the same plane with their like poles downwards, and is designed to show (since the needles were constructed and regulated to have equal times of oscillation) most of the phenomena of the longitudinal transmission of waves.

November 14.—Sir W. H. Bailey, president, in the chair.—Seaweed: C. L. **Barnes.** The author read some extracts from the classical writers which showed in how little esteem seaweed was held by the ancients, it being regarded by them as the most useless of things. He then showed, by an enumeration of some of the uses to which

seaweed is now put, that the moderns had effectually removed this reproach that had been put upon it.—An experiment showing some convection effects in a heated liquid: C. H. **Burgess.** A U-tube is filled in the lower half with hydrochloric acid coloured by a dye, and in the upper with plain acid, and the liquids are allowed to diffuse so as to give a shaded band. The liquid is then heated by the passage of an electric current, and is resolved into a series of well marked layers.

Paris.

Academy of Sciences, November 27.—M. Troost in the chair.—On the distillation of copper: Henri **Moissan.** Copper can be readily distilled in the electric furnace. When the vapour is condensed on a cool body, a felted mass of copper filaments is obtained, presenting all the properties of ordinary metallic copper. Copper at its boiling point dissolves carbon, graphite, partly crystalline and partly amorphous, separating out on cooling.—On the benzylidene derivatives of anthrone and anthranol: A. **Haller** and M. **Padova.** Amongst the reduction products of anthraquinone, Liebermann isolated a compound $C_{14}H_{10}O$, to which one of two formulæ could be assigned. The reactions described in the present paper show that this behaves as a tautomeric body, giving rise to derivatives of the ketone, anthrone.—Researches on intensive nitrification: A. **Muntz** and E. **Laine.** The principal aim of the present research was to find out a means of producing nitre on a large scale for the manufacture of explosives. Animal charcoal has been found to be the best support for the nitrifying organism when strong solutions of ammonium salts are employed, a litre of animal charcoal giving 8·1 grams of nitre per day. The maximum concentration of ammonium sulphate permissible has been found to be 7·5 grams per litre. It is shown that it would be possible to produce nitrates in quantities sufficient for the manufacture of explosives in the case of the external supply being stopped.—On the total eclipse of the sun of August 30, 1905: Ch. **André.** It is shown that the study of the eclipse by a series of micrometric measurements gave results at least as good as the direct determination of the times of the external contacts.—On the luminous intensity of the solar corona during the total eclipse of August 30, 1905: Charles **Fabry.** The observations were carried out at Burgos with a Lummer photometer. The intensity found was about three-quarters that of the full moon.—On groups of continuous curves: Maurice **Fréchet.**—On the non-uniform divergence and convergence of Fourier's series: H. **Lebesgue.**—On the coefficient of utilisation of helices: Edgar **Taffoureau.** A motor of 205 horsepower, working two helices of 7·767 metres diameter, can sustain a useful weight of 506 kilograms.—On the definition of the magnifying power of microscopical objectives: L. **Malassez.** The author proposes to define the magnifying power as the magnification produced by the objective at unit distance from its posterior face.—Researches on the purity of electrolytes. The determination of an upper limit of hydrolysis of concentrated saline solutions by the use of symmetrical liquid chains presenting a fresh surface of contact: M. **Chanoz.**—The difference of potential under which the kathode rays are produced: Jean **Malassez.** The author's experiments tend to show that, contrary to the views put forward by J. J. Thomson, the difference of potential under which the kathode rays are produced is the difference actually existing between the anode and the kathode.—The decomposition of ammonium sulphate by hot sulphuric acid in the presence of platinum: Marcel **Delépine.** In the presence of platinum, ammonium sulphate is destroyed by boiling sulphuric acid. The fact has an important bearing on the determination of nitrogen by the Kjeldahl method.—On a commercial silicide of copper: Paul **Lebeau.** A commercial specimen of copper silicide contained 51 per cent. of free silicon, 44 per cent. of copper silicide, and 4 per cent. of silicide of iron. The silicide was isolated, and, contrary to the accepted view, and in spite of the excess of free silicon, was found to consist of $SiCu_4$ instead of $SiCu_2$.—Chemical oxydases acting in the presence of hydrogen peroxide: G. **Baudran.**—The molecular refraction and dispersion of compounds containing the acetylenic grouping: Charles **Moureau.** It is shown that the additive law in the case of the molecular refraction and dispersion of substituted acetylenes does not correspond with the experimental facts.—The petrographical examination of some volcanic rocks from the Tuamotou Islands and Pitcairn Island: Albert **Michel-Lévy.**—On sterile fruits developed without the intervention of the male element: Th. **Solacolu.** The reserves accumulated at the base of the flower or in the neighbouring parts with a view to the normal development of the pistil after fertilisation are utilised in certain species, even when fertilisation has not taken place, with the formation of a false fruit.—On a new enemy of the coffee plant in New Caledonia: J. **Gallaud.** The disease is known locally as *Koleroga* or *Candellilo*, and is caused by a fungus, *Pellicularia Koleroga.* Statistical researches on the evolution of the height in flax: Mlle. M. **Stefanowski** and M. Henri **Chrétien.**—The cervical covering in the nauplius stage of *Artemia salina*: Nicolas **de Zograf.**—On a supposed case of reproduction by budding in annelids: Ch. **Gravier.**—The trophoplasmic spherules of the ciliated infusoria: J. **Kunstler** and Ch. **Gineste.**—Researches on a supposed ovulase of spermatozoids: Antoine **Pizon.** Pieri's theory, that the segmentation of the egg is started by a ferment (ovulase) of spermatic origin, has been examined experimentally under more rigorous conditions than those obtaining in Pieri's original experiments, and no evidence of the existence of such a ferment was obtained. The author's conclusion is that Pieri's experiments were not carried out with sufficient care.—The toxic power of the seminal fluid and general considerations on the poisonous character of the genital products: Gustave **Loisel.**—On the influence of the salts intimately related to the albumenoids and to the diastatic materials in proteolysis: G. **Malfitano.**—On the function of salts on the production of activity in the pancreatic juice: the specific action of calcium: C. **Delezenne.**—The oxidation of organic substances by ferrous sulphate in the presence of extracts of animal tissues: F. **Battelli.**—The emersion of the land during the Cretaceous period in Greece: Ph. **Négris.**—On the geological structure of the Cantabrian Cordillera in the province of Santander: Pierre **Termier.**—On the Carboniferous and Permian deposits in Corsica: M. **Deprat.**—The layer of fossil vertebrates of Maragha: M. **de Mecquenem.**—Measurements of the intensity of the earth's electric field and of the ionisation of the atmosphere during the total eclipse of the sun of August 30, 1905: G. **Le Cadet.**

Calcutta.

Asiatic Society of Bengal, November 1.—Some remarks on the geology of the Gangetic plain: E. **Molony.** The present valley of the Ganges in the United Provinces of Agra and Oudh has been excavated from an older alluvium, the eroding power of the river being due to submergence in the lower part of the course of the river at some remote period. The older alluvium sometimes forms islands in the midst of the newer alluviums, or Khadir, and is characterised by the presence of nodular limestone (Kankar). The boundary between the two formations is usually distinct. The main direction of the course of the river is determined by the channels in the older alluvium, erosion in which takes place very slowly. In stiff clay the average rate is 11 feet per annum. The records of the Lucknow boring indicate that the strata at a depth of more than 1000 feet are inclined, probably from north to south, and this is taken as evidence of a relative submergence of the southern portion of the Gangetic plain.

Note on the species, habits, and external characters of the dugong: Dr. N. **Annandale.** The author has examined a considerable series of Indian and Australian skulls and skeletons of Halicore. He regards the differences between them as individual, and sees no reason to recognise more than one species, *H. dugong.* He gives the measurements of a fully adult male recently caught in the Gulf of Manaar, and describes its external characters, especially those of the head and mouth. He points out that the dugong has probably altered its habits considerably within the last half-century, at any rate in Indian waters, and shows that its food includes true algæ.—*Hedyotis sisaparensis*, a hitherto undescribed Indian species: Captain A. T. **Gage.** Description of a new species of Hedyotis found by the author in the Calcutta Herbarium, from the Nilgiri district. It is most nearly related to *H. mollis*

(Wall.).—Materials for a flora of the Malayan Peninsula, No. 18: Sir George **King**, K.C.I.E., F.R.S., and J. S. **Gamble**, F.R.S. Owing to an unforeseen cause of delay, it has been found necessary to postpone the publication of the natural orders No. 75, Apocynaceæ, No. 76, Asclepiadaceæ, and No. 77, Loganiaceæ, for a short while; consequently the present part, No. 18 of the "Materials for a Flora of the Malayan Peninsula," contains the orders which succeed, viz. No. 79, Hydrophyllaceæ, to No. 85, Lentibulariaceæ, inclusive, together with No. 87, Bignoniaceæ, and No. 88, Pedalineæ. No. 78, Gentienaceæ, has already appeared in part xvii., and No. 86, Gesneraceæ, will come later on.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 7.

ROYAL SOCIETY, at 4.30.—The Periodogram and its Optical Analogy; with an Illustration from a Discussion of Observations of Sun spots: Prof. A. Schuster, F.R.S.—(1) On a Property which holds good for all Groupings of a Normal Distribution of Frequency for two Variables, with Applications to the Study of Contingency-tables for the Inheritance of Unmeasured Qualities; (2) On the Influence of Bias and of Personal Equation in Statistics of Ill-defined Qualities: an Experimental Study: G. Udny Yule.—On the Inheritance of Coat-colour in Horses: C. C. Hurst.—Further Experiments on Inheritance in Sweet Peas and Stocks (Preliminary Account): W. Bateson, F.R.S., E. R. Saunders, and R. C. Punnett.—A Biometrical Study of Conjugation in Paramæcium: Dr. Raymond Pearl. On Mathematical Concepts of the Material World: A. N. Whitehead, F.R.S.—The Determination of the Osmotic Pressure of Solutions by the Measurement of their Vapour Pressures: The Earl of Berkeley and E. G. Hartley. The Vertical Temperature Gradients on the West Coast of Scotland and at Oxshott, Surrey: W. H. Dines, F.R.S.—The Combination of Hydrogen and Oxygen in contact with Hot Surfaces: Dr. W. A. Bone, F.R.S., and R. V. Wheeler.—Fifth and Sixth Catalogues of the Comparative Brightness of the Stars: in Continuation of those printed in the *Phil. Trans.* for 1796–99 (Prepared for press from the original MS. Records by Colonel J. Herschel, R.E., F.R.S.): The late Dr. Herschel, F.R.S.—On the Cytology of Malignant Growths: Prof. J. B. Farmer, F.R.S., J. E. S. Moore, and C. E. Walker.—A Gas Calorimeter: C. V. Boys, F.R.S.

SOCIETY OF ARTS, at 4.30.—The Partition of Bengal: Sir James A. Bourdillon, K.C.S.I.

CHEMICAL SOCIETY, at 8.30.—The Constitution of Nitrites, Part I., Two Varieties of Silver Nitrite: P. C. Rây and A. C. Ganguli.—The Products of Heating Silver Nitrite: E. Divers.—Ethyl Piperonylacetate: W. H. Perkin, Jun., and R. Robinson.—A Contribution to the Chemistry of Saccharin: F. D. Chattaway.—The Action of Heat on α-Hydrocarboxylic Acids, Part II.: H. R. Le Sueur.—Studies on Optically Active Carbimides, Part II., The Reactions between 1-Menthylcarbimide and Alcohols: R. H. Pickard, W. O. Littlebury, and A. Neville.—The Action of Ultra-violet Light on Moist and Dried Mixtures of Carbon Monoxide and Oxygen: S. Chadwick, J. E. Ramsbottom and D. L. Chapman.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Charing Cross Company's City of London Works: W. H. Patchell.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—Concrete Mixers: Dr. J. S. Owens.

LINNEAN SOCIETY, at 8.—On the Ætiology of Leprosy: Dr. Jonathan Hutchinson, F.R.S.—Some Notes on the Life-history of *Margaritifera Paneseae*: A. W. Allen.—*Exhibition*: Photographs of a Luxuriant Specimen of *Shortia uniflora*, in the Rock-garden of Mr. W. T. Hindmarsh, at Alnwick.

RONTGEN SOCIETY, at 8.15.—The Spontaneous Action of Radium and other Bodies on Gelatin Media: J. Butler Burke.

FRIDAY, DECEMBER 8.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Results of Recent Investigations Relating to Sun-spot Periods: Prof. A. Schuster.—On the Present State of Lunar Nomenclature: S. A. Saunder.—On a New Method of Determining the Moon's Position Photographically: E. B. H. Wade.—Reproduction photographique des Réseaux photographiques: H. Bourget.—(1) Position of the Axis of Mars; (2) Comparative Charts of the Region following δ Ophiuchi: Percival Lowell. Comparison of the Results from the Falmouth Declination and Horizontal Force Magnetographs on Quiet Days in Years of Sun-spot Maximum and Minimum: Dr. Charles Chree.—Note on the Astronomical Value of Ancient Statements of Solar Eclipses: Prof. Simon Newcomb.—On the Conditions Determining the Formation of Cloud Spheres and Photospheres: A. W. Clayden.—On Testing Parabolic Mirrors; with some Results of the Tests as Applied to some Mirrors at Oxford: Rev. C. D. P. Davies.—*Promised paper*: On the Astronomical Observations recorded in the Nihongi, the Ancient Chronicle of Japan: E. B. Knobel.

MALACOLOGICAL SOCIETY, at 8.—(1) A Revision of the Species of Cyclostomatidæ and Liotiidæ occurring in the Persian Gulf and North Arabian Sea; (2) Description of Two Species of Marine Shells from Ceylon: J. Cosmo Melvill.—A Pteropod Alias: (*a*) C. Hedley, (*b*) E. R. Sykes.—(1) Descriptions of Four new Species of Marine Shells from Ceylon; (2) Description of a new Species of Physa from N.W. Australia: H. B. Preston.—Notes (1) on the Dates of Publication of J. D. Wilhelm Hartmann's "Erd- und Süsswasser-Gasteropoden," 8vo, St. Gallen, 1840; (2) On Some "Feeding Tracks" of Gastropods; (3) On Cement as a Slug-killer: B. B. Woodward.

MONDAY, DECEMBER 11.

SOCIETY OF ARTS, at 8.—The Measurement of High Frequency Currents and Electric Waves: Prof. J. A. Fleming, F.R.S.

TUESDAY, DECEMBER 12.

ZOOLOGICAL SOCIETY, at 8.30.

FARADAY SOCIETY, at 8.—The Physics of Ore Flotation: J. Swinburne and Dr. G. Rudorf.—The Concentration of Metalliferous Sulphides by the Flotation Process: Prof. A. K. Huntington.—The Ions of Pure Water: Prof. J. Walker, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Adjourned Discussion*: The Steam-Turbine: Hon. C. A. Parsons, C.B., F.R.S., and G. G. Stoney.—

WEDNESDAY, DECEMBER 13.

SOCIETY OF ARTS, at 8.—The Commerce and Industries of Japan: W. F. Mitchell.

THURSDAY, DECEMBER 14.

ROYAL SOCIETY, at 4.30.—*Probable papers*: An Investigation into the Structure of the Lumbo-sacral coccygeal Cord of the Macaque Monkey (*Macacus sinicus*): Miss M. P. Fitzgerald.—On the Distribution of Chlorides in Nerve Cells and Fibres: Prof. A. C. Macallum and Miss M. L. Menten.—The Mammalian Cerebral Cortex, with Special Reference to its Comparative Histology. I. Order Insectivora: Dr. G. A. Watson.—Observations on the Development of Ornithorhynchus: Prof. J. T. Wilson and Dr. J. P. Hill.—Further Work on the Development of the Hepatomonas of Kala-Azar and Cachexial Fever from Leishman-Donovan Bodies: Dr. L. Rogers.—The Action of Anæsthetics on Living Tissues. Part I. The Action on Isolated Nerve: N. H. Alcock.—Report on the Psychology and Sociology of the Todas and other Indian Tribes: an Abstract of Work carried out by the Aid of the Gunning Fund of the Royal Society for the year 1901–2: Dr. W. H. R. Rivers.—On the Sexuality and Development of the Ascocarp of *Humaria Granulata*, Quel.: V. H. Blackman and Miss Helen C. I. Fraser.—On the Microsporangia of the Pteridospermea with remarks on their Relationship to Existing Groups: Robert Kidston, F.R.S.—The Araucarieæ, Recent and Extinct: A. C. Seward, F.R.S., and Miss S. O. Ford.

MATHEMATICAL SOCIETY, at 5.30.—On Well-ordered Aggregates: Prof. A. C. Dixon.—Tables of Coefficients for Lagrange's Interpolation Formula: Col. R. L. Hippisley.—On the Representation of certain Asymptotic Series as Convergent Continued Fractions: Prof. L. J. Rogers.—On a New Cubic Connected with the Triangle: H. L. Trachtenberg.—Some Difficulties in the Theory of Transfinite Numbers and Order Types: Hon. B. A. W. Russell.—The Imaginary in Geometry: J. L. S. Hatton.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—*Adjourned Discussion*: The Charing Cross Company's City of London Works: W. H. Patchell.

FRIDAY, DECEMBER 15.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—*Adjourned Discussion*: The Seventh Report to the Alloys Research Committee: On the Properties of a Series of Iron-Nickel-Manganese-Carbon Alloys: Dr. H. C. H. Carpenter, and Messrs. R. A. Hadfield and Percy Longmuir.—*Paper*: Behaviour of Materials of Construction under Pure Shear: E. G. Izod.

PHYSICAL SOCIETY (at Royal College of Science, South Kensington), at 7.—Exhibition of Electrical, Optical and other Physical Apparatus.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Tests of Street Illumination in Westminster: E. E. Mann.

AËRONAUTICAL SOCIETY, at 8.—The Acoustical Experiments carried out in Balloons by the late Rev. J. M. Bacon: Miss Gertrude Bacon.—The Aeromobile: F. Webb.—A New Continuous Impulse Petrol Motor for Dynamic Flying Machines: W. Cochrane.

A GREAT NATURALIST.

My Life: a Record of Events and Opinions. By Alfred Russel Wallace. Vol. i., pp. xii+435; vol. ii., pp. viii+459. With facsimile letters, illustrations, and portraits. (London: Chapman and Hall, Ltd., 1905.) Price 25*s.* net.

EVERYONE will be glad that the Nestor of the evolutionist camp has been able himself to tell us the story of his life. It has been a long life of over fourscore years, full of work, rich in achievement, starred with high ideals, and the story of it must have been pleasant to write as it is pleasant to read. It has been many-sided to a greater degree than that of most scientific investigators, for Alfred Russel Wallace has always had more than professional irons in the fire, and has always been as much interested in practising biology as in theorising about it At the editor's request we have confined our attention, however, to what the author tells us of his work as naturalist and biologist, though it is difficult, and not altogether legitimate perhaps, to abstract off one aspect of a life in this fashion.

There does not seem to have been anything definable in Wallace's inheritance to account for his becoming a great naturalist. Nor was there much in his nurture to lead him in that direction except that he was country-bred in beautiful and interesting places. Thrown early on his own resources to make his way in life, he began when about fourteen to work at surveying—in which Herbert Spencer had also his early discipline—and it was in trying to understand his instruments and the earth he measured that he first became scientific. He tells us that in his solitary rambles, nature gradually laid hold of him, claiming to be understood as well as enjoyed. From the stars and the earth his interest spread to flowers, and, with the help of Lindley's "Elements" and Loudon's "Encyclopædia of Plants," he became a keen field-botanist. He began to feel "the joy which every discovery of a new form of life gives to the lover of nature," and this was the turning-point of his life.

During a year of school-teaching at Leicester (1844), Wallace got to know Bates, who made him an enthusiastic entomologist, "opening a new aspect of nature," and he also read Malthus's famous essay, "without which I should probably not have hit upon the theory of natural selection." Another book that impressed him was Humboldt's "Personal Narrative of Travels in South America," which awakened a desire to visit the tropics, a desire soon strengthened by Darwin's "Voyage of the *Beagle*." It is interesting to find that as early as 1845 Wallace was speculating upon the origin of species, and had a warm appreciation of the "Vestiges of the Natural History of Creation."

Early in 1848, when he was twenty-five, Wallace set out, along with Bates, to explore and collect on the Amazon, and on the tale of his adventures, long since told, the "Life" throws some sidelights. There is a vivid description of the disastrous fire on board the rubber-laden ship which brought Wallace part of the way home in 1852. The holocaust of all his treasures was hard to bear, but what had been sent on during his journey, and those notes and drawings which were saved from the fire, sufficed to lay the foundations of his scientific reputation, and, perhaps, as he says, the disaster was, for him, a blessing in disguise, for it made him continue his *Wanderjahre*.

The "central and controlling" chapter in Wallace's life was his eight years' wandering throughout the Malay Archipelago, the story of which has fascinated many thousands of readers. He had found his vocation, and enthusiasm grew upon him. "Who ever," he wrote, "did anything good or great who was not an enthusiast?" The love of solitude grew upon him; it was so "very favourable to reflection." For though he was earning a competency by collecting, and though his knowledge of many groups of animals became expert, he was always pondering over big problems, and some of his friends at home shook their heads at his "theorising." "The problem of the origin of species was rarely absent from his thoughts," and at Sarawak, in 1855, he wrote what Huxley called a "powerful essay" on "The law which has regulated the introduction of new species"—a hint of what was coming. At Ternate, in 1858, when ill with intermittent fever, he began thinking over what he had learned from Malthus, and the theory of natural selection "suddenly flashed upon him." He wrote straight off to Darwin, and everyone knows how the two papers were read on the same day at the Linnean Society, and how the two discoverers were united in a friendship than which there has been nothing finer in the history of science.

From 1862 to 1871 Mr. Wallace lived in London, and the "Life" gives an account of his scientific and literary labours, and interesting glimpses of many scientific men whom he came to know, such as Lyell, Spencer, Huxley, W. B. Carpenter, and St. George Mivart. He tried for various posts, *e.g.* the secretaryship of the Royal Geographical Society (which Mr. Bates obtained), and the guardianship of Epping Forest (in connection with which he had some luminous ideas), but he was left free to continue his literary and scientific work, and to try to make things better for his country. Soon after his marriage, in 1866, he began to migrate by stages into the country—to Grays (where he wrote his "Geographical Distribution"), to Croydon (where he wrote his "Island Life"), to Godalming, to Parkstone, and was able to live quietly on his earnings and on a well-merited Civil List pension. Apart from his tour in America, where he gave the Lowell lectures in 1886, occasional holidays, *e.g.* at Davos, and occasional unprofitable scrimmages, his life was very uneventful, as men count events. By nature quiet, gentle, and reflective, he had no ambitions save for truth and justice; he was satisfied with plain living and high thinking, and the esteem of all who really knew him. Thus for many years he has cultivated his garden and served his fellowmen.

The "Life" contains many interesting appreciations of other naturalists, but we must confine ourselves to the relations between Darwin and the author. From his solitude in Malay Wallace wrote home in regard to "The Origin of Species":—

"I have read it through five or six times, each time with increasing admiration. It will live as long as the Principia of Newton. Mr. Darwin has given the world *a new Science*, and his name should, in my opinion, stand above that of every philosopher of ancient and modern times."

To Mr. Bates he wrote:—

"I do honestly believe that with however much patience I had worked and experimented on the subject, I could *never have approached* the completeness of his book, its vast accumulation of evidence, its overwhelming argument, and its admirable tone and spirit. I really feel thankful that it has *not* been left to me to give the theory to the world."

As everyone knows, Wallace parted company with Darwin over the possibility of giving a "natural history" interpretation of man's highest qualities, and in one of his letters Darwin expressed the fear that his selectionist interpretation would quite kill him in Wallace's good estimation. But the author writes:—

"I never had the slightest feeling of the kind he supposed, looking upon the difference as one which did not at all affect our general agreement, and also being one on which no one could dogmatise, there being much to be said on both sides."

Wallace also differed from Darwin in regard to the reality of sexual selection through female choice, as to the distribution of Arctic plants in south temperate regions, as to the feasibility of the provisional hypothesis of pangenesis, and as to the transmissibility of acquired character. On the whole, however, he admits that those critics are not far wrong who describe him as more Darwinian than Darwin, and even in the title of one of his most effective books he persisted in his magnanimous subordination of himself. The fact is, the friends were too keen in the pursuit of truth to trouble about the boundaries of their personal credit. Neither begrudged the other his due meed of praise. Thus, if we may quote once more, we find Darwin writing to Wallace:—

"I hope it is a satisfaction to you to reflect—and very few things in my life have been more satisfactory to me—that we have never felt any jealousy towards each other, though in some sense rivals. I believe I can say this of myself with truth, and I am absolutely sure that it is true of you."

In addition to his statement of the theory of natural selection, his travels, and his work on distribution, Mr. Wallace has in many ways enriched natural history in the wide sense. There is his theory of the "warning colours" of inedible insects, his theory of the correlation between the colours of female birds and the nature of the nest, his theory of "recognition-marks," his criticism of sexual selection by choice on the female's part, his argument that much that is called "instinctive" is due to instruction and imitation, his conclusions as to the Arctic elements in south temperate floras, his emphasis on mouth-gesture as a factor in the origin of language, his strong opinions as to the part natural selection has played and still plays in the social evolution of mankind. We might mention other contributions—as to the permanence of oceanic and continental areas, as to the causes of glacial epochs, as to the glacial erosion of lake-basins, as to the affinities of the Australian aborigines—but we have said enough. It may be of interest, however, to notice that while Wallace many years ago sided with Weismann, he cannot see his way to recognise the validity of the recent theories of discontinuous variation and mutation.

In thinking of the work of Alfred Russel Wallace, we see him as a "synthetic type," combining the virtues of the old naturalist traveller with those of the modern biologist. On the one hand, we see him with a rich experience of the forms and species of animal life, their distribution, habits, and inter-relations, but with a wide outlook, equally interested in palms and orchids, lakes and mountains. With "a positive distaste for all forms of anatomical and physiological experiment," he never took to any of the usual methods of analysis, and even when he was most preoccupied with species he tells us that he was determined not to become a specialist. So, on the other hand, we see him from first to last as a generaliser, "inquisitive about causes," intent upon "solving the problem of the origin of species," and contributing much thereto. His "Life" also discloses what many have had the privilege of knowing—the delightful personality of one who has had the honour of being "Darwinii æmulum, immo Darwinium alterum," and no ætiologist merely, but a warm-hearted humanist thinker, a fearless social striver, and one who realises the spiritual aspect of the world. He has the satisfaction of a retrospect on a long and happy life of work.

J. A. T.

A HIGHER TEXT-BOOK OF ELECTRICITY AND MAGNETISM.

Magnetism and Electricity for Students. by H. E. Hadley. Pp. x+575. (London: Macmillan and Co., Ltd., 1905.) Price 6*s*.

THE object of this volume is to carry students a stage further than that reached in the author's "Magnetism and Electricity for Beginners." It has been written in response to numerous requests from teachers. Its scope is roughly that of a second- or even third-year college course. Elementary differential and integral calculus is employed, but even this is avoided whenever reasonably practicable. Technical applications are dealt with in a minor way only, the author considering, rightly in our opinion, that they are best relegated to a special treatise.

Turning to the detailed treatment we find many things to attract us. The method adopted for describing electrical phenomena may be alluded to as the "lines of force method." There are a large number of carefully thought out diagrams showing the play of Faraday tubes in various cases. These are in the main very accurate and suggestive as sketch diagrams. In Fig. 112, however—illustrative

of Faraday's ice-pail experiment—care should have been taken to make the lines emanating from the charged ball fall normally upon the vessel. The properties of these lines are not dogmatically asserted, but in general are derived, in the usual way, from the inverse square law of force; exception must, however, be made with respect to the lateral pressure exerted by such tubes. In stating that the inverse square law was experimentally verified first by Coulomb the author seems to have forgotten Cavendish, who, fully twelve years earlier, proved that the index cannot differ from two by more than 1/50th part.

We have alluded already to the diagrams; more care than usual has been exercised in regard to these. We are particularly attracted by one showing the lines of force and induction of a horse-shoe magnet. Compared with the usual paltry sketches of these lines this is most excellent. The student ought to be warned, however, that it represents rather an artificial case, since the poles are taken as concentrated at points. In the absence of this warning the student may be puzzled to account for the peculiar configuration of the system of lines shown. Another diagram which is now finding its way into text-books is one (Fig. 354) showing the lines of *electric* force due to a current. Much emphasis is usually placed on the magnetic field, but the electric field is almost entirely ignored. We are glad to see it now beginning to take its proper place. It may be mentioned that if the conductors be taken as infinitely deep, so as to reduce the problem to a two-dimensional one, the lines of force are a family of rectangular hyperbolæ, while the equipotential lines are the orthotomic hyperbolæ.

Several omissions and errors require attention. In the chapter on mechanics there is no definition of *mass* we are not even told that it is the quantity of matter in a body. It is erroneous to state that electrification and electric currents are forms of energy (p. 22). A hollow soft iron cylinder does not act as a perfect screen to magnetic force for points inside it (p. 65). The proof of the formula for the ballistic galvanometer (p. 282) is imperfect, since it assumes that the current is constant while it flows; whereas it essentially is never so in cases for which this kind of galvanometer is used. A very little change in the proof will put this right. In the formula for simple pendulum or suspended coil the time period should not be written with $\sin\theta/\theta$ in the denominator, since when so written the idea is conveyed that this is the proper form when the difference between $\sin\theta$ and θ is too large to be neglected. In calculating the temperature of a wire when heated by a current the emissivity should not be taken as a constant, for Messrs. Ayrton and Kilgour confirmed Péclet's proof that it depends on the radius; for very thin wires the values go up to many times that quoted, except, of course, in a vacuum. Kelvin's proof of the existence of an E.M.F. *distributed* in a circuit of two metals parts of which are at different temperatures depended on the first law of thermodynamics, and not upon the properties of a Carnot cycle (p. 374). The definition of units is antiquated; those described (p. 515) are now obsolete. On p. 531, in connection with displacement currents the word *displacement* is used on adjacent lines in two senses, with consequent confusion to the meaning. The treatment of the calculation of the propagation of electrodynamic effects (p. 534) which is professedly applicable to the case when the exciting current is travelling along a wire is inapplicable to this case. The display of mathematics in this calculation will convey the erroneous impression of a thorough investigation. The result must be disastrous to a student who is feeling his way toward a knowledge of the subtleties of line-integration round a closed curve. The error arises in part from forgetting that the magnetic induction varies in the direction y as well as in the direction x. Everything is, we believe, put right if the conductor be taken as an infinite plane sheet; the variation which is omitted is in such a case zero.

These few errors are the more unfortunate since we think that the book will prove a very useful one. We frankly think that it has been attempted to put too much into small compass; most sections would be improved by amplification in explanation of principle at the sacrifice of detail. A little excision when this edition is exhausted, a little more attention to logical order and to the development of principles—such suggestions are worth attending to, for the book has the making of a very useful volume.

BUNSEN'S COLLECTED WORKS.

Gesammelte Abhandlungen von Robert Bunsen. Edited by Wilhelm Ostwald and Max Bodenstein. Vol. i., pp. cxxvi+535; vol. ii., pp. vi+660; vol. iii., pp. vi+637. (Leipzig: Engelmann; London: Williams and Norgate, 1904.) Price *2l. 10s.* net.

THE appreciative and critical notices of Bunsen and his work which appeared shortly after his death hardly leave room for a review of the volumes before us. In the Chemical Society memorial lecture, which is justly given the place of honour in the prefatory part of the first volume, Sir Henry Roscoe has given a comprehensive survey of Bunsen's work, and has described the personality of the man in such a way as to earn the gratitude of all old Heidelberg students.[1]

In these three stately volumes we have a complete collection of Bunsen's contributions to science and a book that will form part of the permanent literature of chemistry. It is, indeed, a most striking fact that all Bunsen's writings are in their nature permanent scientific literature, a fact that well deserves pondering at the present time. He made some mistakes, he advanced some conclusions now untenable, but his writings are of faithful observations, careful experiments, laboratory methods. Of speculative theory there is nothing, and of strictly polemical writing also nothing. The books that are included in his writings are accounts of methods of doing things that he him-

[1] An account of Bunsen's scientific work was given by Sir Henry Roscoe in NATURE of April 28, 1881 (vol. xxiii. p. 597), as a contribution to our series of "Scientific Worthies."—EDITOR

self devised—gas analysis, mineral water analysis, flame reactions. It is not easy to describe Bunsen's relation to chemical science. He was a perfect type of "Naturforscher," a word for which there is hardly an English equivalent. He lived in his laboratory, ever absorbed, he seemed, in finding his way through natural problems, like a navigator always on the bridge sailing in an unknown archipelago. His writings are hardly more than his log, and his lectures were the narratives of his own particular voyage in the region called chemistry. To a listener who had a fair knowledge of chemistry and its literature it seemed as if there were no part of inorganic chemistry which Bunsen had not made in some way his own. In the laboratory it was the same; from the making of a borax bead to the execution of the most complicated analysis there was the Bunsen method of doing things. Spectroscopy, gas analysis, and electrolytic chemistry for long seemed wholly his. No chemist had a broader or more philosophical outlook than he; on the one hand he had a profound distrust of theory that went in advance of experiment, and on the other hand he despised all kinds of aimless or recipe work. Of the periodic classification of the elements he said at one time, "Ja, solche Regelmässigkeiten findet man in den Börsenblättern"; of a well known standard work on analysis he said "Koch-buch!" and indignantly ordered its removal. What a memorable experience it was for a student to work with Bunsen through the Russian Mint residues! The innumerable devices of his own, the "nursing" operations at different stages, the tales of his earlier efforts and disasters, the eager hope "vielleicht steckt etwas neues darin," the dry assurance "ja, alle Wochen werden ein Paar neue Platinmetalle entdeckt" all these things come to mind to recall the image of a man in whom the art of a past master was combined with the artlessness of a child.

It is impossible to estimate the influence of such a man; but in the volumes which it is the object of this notice to commend, it is possible to read the record of his work and to catch something of the spirit which animated the worker.

The collected works are published under the auspices of the German Bunsen Society for Applied Physical Chemistry, and are edited by Prof. Ostwald and Dr. Bodenstein. We are therefore assured that the task has been performed with pious care and with fulness of knowledge. The original intention of publishing a biography of Bunsen had to be abandoned owing to his express order, so characteristic, that his literary remains should be destroyed. He also desired that from his own letters in the possession of others nothing of a personal character should be published. The gap thus left is probably not so great as might be imagined, and one feels, after reading the prefatory memoirs by Sir Henry Roscoe, Dr. Rathke, and Prof. Ostwald himself, that we have probably all we really need to know. "Bunsen stories" were doubtless good to those who knew him, but to those who did not they were apt to be like most tales of university dons, and the collection which has been privately published seems rather trivial, and jars somewhat on the ears of the faithful. But the collection of his writings makes a noble monument, and the thanks of all chemists are due to the Bunsen Society and to the two editors who have undertaken the laborious task and have executed it so well.

ARTHUR SMITHELLS.

OUR BOOK SHELF.

The Practical Study of Malaria and other Blood Parasites. By Dr. J. W. W. Stephens and S. R. Christophers. 2nd Revised Edition. Pp. iii+396 and xliv. (London: Published for the University Press of Liverpool by Williams and Norgate, 1904.) Price 12s. 6d. net.

THIS volume gives a very full and complete account of the practical methods employed in the study of malaria and kindred protozoan diseases of man and animals. The book being intended primarily for the use of medical men in the tropics, who may be far from any laboratory, abounds in practical hints and suggestions which will enable good work to be accomplished with a minimum of apparatus, &c.

The methods of making and staining blood-films are given very fully, and the appearances of normal blood and of the various malaria parasites carefully described. In connection with malaria, the methods of catching, breeding, keeping, and feeding mosquitoes for purposes of malaria study receive considerable attention, and the life-history of the mosquito and the characters of a number of the more important species have no less than 200 pages devoted to them. Chapters then follow on the clinical and epidemiological study of malaria, and finally the hæmamœbidæ, trypanosomes, spirochætes, and filariæ are considered. This entails descriptions of the anatomy and classification of the chief species of ticks, fleas, tsetse and other biting flies, and a mass of detail is thus brought together in a form required by the investigator for which he otherwise would have to search in many scattered papers and works of natural history. In this respect the book will be of great value in laboratories of medical protozoology and the like. There are few points to which exception can be taken, for the book is the outcome of the authors' own experience on the subjects of which they write. It may be doubted, however, if methylated spirit can take the place of methyl alcohol for making up the Leishman blood-stain, and the authors' view that blackwater fever is malaria plus hæmoglobinuria excited by chill, quinine, or other simple cause is open to question.

The book can be recommended as a most valuable guide, and the numerous illustrations, diagrammatic though many of them are, enhance its usefulness.

R. T. HEWLETT.

Pictures from Nature. By Richard and Cherry Kearton. Portfolio of fifteen Rembrandt photogravures. Size 15in. × 11in. (London: Cassell and Co., Ltd.) Price 10s. 6d. net.

THE remarkable photographs taken by the Brothers Kearton of animal life in many aspects have often been described in these columns in terms of the highest praise. The fifteen pictures of birds and othe animals, among their natural surroundings, reproduced for the present portfolio, represent the highwater mark of faithful portraiture in natural history.

The plates include the following subjects:—Black throated diver, kittiwakes at home, leverets in their form, kingfisher waiting for its prey, squirrel, puffins

at home, young willow wrens, ring dove or wood pigeon, young cuckoo and sedge warblers, hedgehog, young long-eared owls, gannet or solan goose, peewit or lapwing, sparrowhawk adding sticks to her nest, and the great tit or oxeye.

These handsome pictures provide the best possible tribute to the patient power of silent watching which the Brothers Kearton have developed during the last thirteen years in order to take advantage of opportunities of photographing animals in their natural surroundings.

Meteorologie und Klimatologie. By Prof. Dr. Wilhelm Trabert. Pp. 127; with 37 figures in the text. (Leipzig: Deuticke, 1905.) Price 5 marks.

In this little book, which forms part xiii. of Prof. Klar's "Die Erdkunde," the author attempts to outline the general principles of meteorology and their application to the study of climate in a single work. The meteorological elements, and the making and reducing of observations are first dealt with; next comes a section on atmospheric physics, the distribution of temperature and its variations, the circulation of the atmosphere, evaporation and condensation; and, finally, a section on weather and climate, which includes chapters on weather forecasting, the chief types of climate, and the climatic characteristics of the main land divisions of the globe.

Where so much is attempted in so small compass, there is, of course, constant risk of the treatment of parts of the subject becoming hopelessly inadequate, but Prof. Trabert has succeeded in avoiding this; the essential points are selected with extraordinary skill and presented with great clearness and conciseness. The omission of details of construction of instruments in part i. is especially satisfactory—most books on meteorology are overburdened with matter which is only wanted by practical observers—although in some cases more modern types of instrument might have been selected for illustration. The most successful section of the book is, in our opinion, that on atmospheric physics, in which the vertical distribution of temperature and the forms of isobaric surfaces are given the prominence they deserve, but do not always get.

Prof. Trabert's book is an excellent introduction to such classics as Hann's "Lehrbuch" and "Klimatologie," on which it is to a certain extent modelled, and we strongly commend it to elementary students and teachers.

A Popular Introduction to Astronomy. By the Rev. Alex. C. Henderson. Pp. 114. (Lerwick: T. and J. Manson, 1905.) Price 2*s.* 6*d.* net.

In this book there are three chapters, occupying sixty-three pages, and a series of thirteen "notes" which take up the remainder of the text. In chapter i. we find a very general, yet simple and instructive, description of the solar system, its probable origin, and the nature, appearance, dimensions, and distances of its various individual components. The explanations given are brief, but they are lucid, and the verbal illustrations are homely enough to appeal to the simplest minds. Chapter ii. deals with the apparent and real motions of the heavenly bodies, and here again the beginner should find no difficulty in grasping the fundamental ideas. Comets are discussed in chapter iii., which really consists of a description of Biela's famous comet and of the meteoritic genesis of these bodies.

The thirteen "notes" comprise a *mélange* apparently consisting of extracts and examples taken from the author's note-book, and it is rather difficult to see to what class of reader they will appeal. Portions of them are certainly too erudite to suit real beginners, whilst they are not of the form to appeal to more advanced students. For example, the observing of the sunrise, combined with the consultation of a year book, would hardly answer to the description of an "accurate method" of determining time. Double stars, climatic variations, auroræ, eclipses, the lunar phases, and the zodiac are amongst other things dealt with in this section of the book. W. E. R.

Fragmenta Phytographiae Australiae occidentalis. By L. Diels and E. Pritzel. Pp. 608. (Leipzig: W. Engelmann, 1905.)

Although the floras of the different Australian colonies present a certain homogeneity that unites them into a definite "Flora Australiensis," there is also a considerable diversity between the floras of the eastern and western sides of the continent; that of the western half is distinguished by its richness, the singular modifications due to physical conditions and the large proportion of endemic species. Exclusive of the northern tropical region, the vascular plants of Western Australia, according to the evidence of the Government botanist, Mr. A. Morrison, do not fall far short of 4000 species, and most of these are found in the south-west. The writers of this volume travelled through this portion of the colony, and also penetrated into the interior from Geraldton to Cue, and as far as Ranowna and Menzies in the Coolgardie district. Phytogeographical limits are determined mainly by the rainfall, which reaches a maximum of 39 inches in the neighbourhood of Cape Leeuwin and diminishes rapidly to 9 inches at Shark Bay in the North and Southern Cross inland; the botanical provinces outlined in this volume have been mapped out in accordance with the rainfall.

The book is primarily a systematic compilation of the authors' collections, and although there are interesting notes on morphology and habit, the principal feature is the intimate knowledge which the authors display of the distribution of the various species. A revised arrangement of the Verbenaceæ is given, with analytical keys and numerous illustrations. Additions have been made to most of the typical genera, to mention only Acacia, Drosera, Hibbertia, and several of the Myrtaceæ. Taken in conjunction with Bentham's "Flora Australiensis," Baron von Mueller's "Fragmenta," and Spencer le Moore's notes, these "Fragmenta" provide the necessary data for a fairly complete flora of the colony. Dr. Diels proposes to write a continuous phytogeographical account later, wherein it may be expected that he will summarise the extraordinary modifications of the desert and other plants that are no less unique than those of the Egyptian desert flora which Volkens has so vividly portrayed.

Sporting Sketches. By E. Sandys. Pp. vii+389; illustrated. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1905.) Price 7*s.* 6*d.* net.

Mr. Edwyn Sandys is so well known to bird-lovers and sportsmen in general by such works as "Upland Game Birds" that any volume of a somewhat similar nature is almost sure of a hearty reception on the part of that section of the public to which it more specially appeals. In the volume before us the author has collected together a number of articles on sporting subjects which originally appeared in that excellent American sporting magazine *Outing*, and to these he has apparently added others which now see the light for the first time. Whether, however, new or old—and the author seemingly gives us no clue on this point—the articles have such a freshness about

them, and savour so strongly of the prairie or the river bank, that the lover of an outdoor life must be hard indeed to please if he cannot find matter of interest on almost any page to which he may happen to turn. The chapter-headings in some instances appear to be designed, at least to an English reader, to conceal rather than to elucidate the author's subjects, and we venture to think that some less recondite titles than "The Witchery of Wa-Wa" and "A Matter of Mascalouge" might have been selected without detriment to the picturesque style which the author apparently favours. But when once this little difficulty has been overcome, the reader will be able to find his way about the book, and select those sections in which he may be more specially interested.

The greater part of the book is devoted to fishing—both in sea and river—and feathered game shooting, and the English reader who desires to know the kind of sport afforded by ruffed grouse and "bob white" will find his requirements fully satisfied in the author's pages. Nor will the naturalist fail to find matter well worth his notice; and personally we have been specially interested in the account of the death-feigning instincts exhibited by the Carolina rail. Seemingly, when it thinks itself unable to escape, one of these birds suddenly "stiffens, topples over, and apparently expires. It may be taken up and examined for a considerable time without its betraying any signs of life. Place it among its dead fellows in the shooting-boat, and after a longer or shorter interval it may astonish its captor by either starting to run about, or by taking wing and fluttering away in the characteristic flight."

This is only one of many instances where strange habits of animals are recorded, and if not new they are always interesting and worth the re-telling. As a sample of the better class of sporting literature Mr. Sandys's work would be difficult to beat. R. L.

Ships and Shipping. By Commander R. Dowling. With a preface by Lieut. W. G. Ramsay Fairfax, R.N. Second Edition. Pp. xv+423. (London: A. Moring, Ltd., 1905.) Price 5s. net.

A very excellent little volume and a most handy addition to any shipping office. The naval information makes it also a very useful book to naval officers. One slight improvement would be useful—port-to-port distances round the coast of Great Britain and Europe; for example, London to Plymouth.

H. C. Lockyer.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The late Sir John Burdon-Sanderson.

The account of the life of Sir John Burdon-Sanderson in Nature of December 7 is so admirable that any addition to it may seem superfluous. Yet, as one who knew Burdon-Sanderson for more than thirty-seven years, and who owed more to him than language can well express, I shall be grateful if you will allow me to say a few words more about him. It seems to me that in one respect men may be likened to mountains. The Matterhorn rises sharply to a single peak, and there can be no doubt as to its summit. Monte Rosa has more than one summit, so nearly on a level that a stranger would be unable to say which is highest, and although each is higher than the Matterhorn, the enormous bulk of the mountain takes away from their apparent height and makes them less imposing. In the same way it is easy to say what the great work has been of any man who has distinguished himself in a limited subject, but when a man's work ranges over a wide sphere it is not so easy. The account of Sir John Burdon-Sanderson's life in last week's Nature clearly shows the wide extent of his activity and the great number of epoch-making discoveries which he made. If a scientific man were asked which of these is the greatest, he would probably answer according to his own personal bias. One man would name his unique researches on motion in plants; another his discovery of the possibility of attenuating anthrax virus and thus producing immunity from the disease; a third his researches on circulation and respiration; and a fourth his work on muscle and nerve. But all these things, important as they are, each one being sufficient to make a man famous in a special department, were only isolated outgrowths of his great work, and did not constitute it. I believe that I am right in saying that Burdon-Sanderson's life-work may be defined in three short sentences:—(1) He revolutionised physiology and pathology in this country; (2) he found them consisting of book-learning and microscopic observation; (3) he left them experimental sciences.

When he first constructed a kymographion in 1867 by the aid of a tin-plate worker near the Middlesex Hospital, to which he was then attached, there was not, with the exception of a few specimens of Marey's sphygmograph, a single recording physiological instrument in use in the whole of this country. Now they are to be found in every physiological laboratory, and every student knows how to use them. When he began to work at pathology, it consisted chiefly in descriptions of the naked-eye and microscopical appearances of specimens of morbid anatomy. Now the action of disease-germs and of toxins and the reaction of the organism to them, the processes of disease and not its results, engage the chief attention of pathologists, and the knowledge which experiments on these processes have afforded regarding the means of producing immunity and of curing by antitoxic sera has lessened, and is daily lessening, the wholesale destruction of life by epidemic diseases.

How Burdon-Sanderson accomplished his great work by his researches, by his writings, by his example, and by his personal influence was well described in last week's Nature, but I may perhaps be permitted to mention my own case as an example of what Burdon-Sanderson did for young men. I came to London knowing only one man, who from age and infirmity was unable to help me; but fortunately for me I had a letter of introduction to Burdon-Sanderson. Instead of merely saying a few civil things and then leaving me alone, as he might well have done, he invited me to his house, advised me as to my career, obtained for me a lectureship in the Middlesex Hospital, to which he was then attached, gave me the free use of his laboratory, afforded me facilities for both experimental and literary work, and, in short, laid for me the foundation of any success I may since have had, so that it is mainly to him that I owe it. How many there are whom he has treated as he did me I do not know, for he did not let his left hand know the good his right hand was doing, but I do know that at least two others, Dr. Ferrier, who has done such splendid work in physiology, and Dr. Klein, who has done the same in pathology, owe, like me, their first establishment in London to Burdon-Sanderson. Such personal help as this in enabling young men to pursue a scientific career must not only be regarded as an evidence of the kindness and benevolence of his character, but must be reckoned along with his researches, his writings, his example, and his personal influence as a means whereby he accomplished his great work of revolutionising physiology and pathology in this country.

Lauder Brunton.

Nomenclature of Kinship; its Extension.

The method I adopted in your columns, August 11, 1904, of briefly expressing kinship has proved most convenient; it has been used in a forthcoming volume by Mr. E. Schuster and myself on "Noteworthy Families." I write now to show that it admits of being *particularised* by the use of foot-figures, as in the following example, which

refers to the more highly placed relatives of the newly elected King of Norway.

Haakon VII., King of Norway (*b.* 1872).

fa_{1s}	Frederick, Crown Prince of Denmark (*b.* 1843).
$fa_{1s}\ fa$	Christian IX., King of Denmark.
$fa_{1s}\ bro_2$	George I., King of the Hellenes (*b.* 1845).
$fa_{1s}\ si_2$	Dagmar, widow of Alexander III., Tsar of Russia, who *d.* 1894
$fa_{1s}\ si_2\ son_1$	Nicholas II., Tsar of Russia (*b.* 1868).
$fa_{1s}\ si_1$	Alexandra, Queen of England (*b.* 1844).
$fa_{1s}\ si_1\ son_1$	George, Prince of Wales (*b.* 1865).
$fa_{1s}\ si_1\ da_3$	also *wife*, Princess Maud (*b.* 1869) of England.

The formulæ are to be read thus:—"his (the K. of Norway's) father is the 1st (eldest) son, and is Frederick, C.P. of Denmark; "his (the K. of Norway's) father's father is Christian IX."; . . . "his father's 2nd sister's 1st son is Nicholas II."; . . . "his father's 1st sister's 3rd daughter, who is also his (the K. of Norway's) wife, is the Princess Maud." These foot-figures need not interfere with the simplicity of the general effect, while they enable a great deal of additional information to be included.

FRANCIS GALTON.

Atomic Disintegration and the Distribution of the Elements.

MR. DONALD MURRAY'S letter (p. 125) deals with a subject which I have been attempting, now for more than a year, to attack experimentally. A similar experience to that which Mr. Murray describes as the experience of a lifetime occurred to me eighteen months ago in a visit to the gold mines of Western Australia. Since then my thoughts have been less concerned with the radio-elements than with those like gold, platinum, thallium, indium, &c., which resemble radium in the minuteness and approximate constancy of the proportion in which they occur in nature.

It is wonderful to reflect that mankind for thousands of years has been passionately and determinedly engaged in the search for gold, not on account mainly of its useful qualities, but on account of its comparative scarcity. The history of gold-getting presents a strange uniformity. The search has been rewarded always with about the same qualified measure of success, never with such success that the value of gold has seriously depreciated. The common saying that about the same amount of gold has to be put into the earth in order to dig it out holds an economic and probably a scientific truth. For may we not consider that the history of these centuries of search, carried on with a tenacity of purpose and a continuity approached in the case of no other element, shows clearly that a natural law is here involved no less than in the case of radium or polonium? The history of gold-getting appears to be substantially the same in all countries in all times. We have the initial prospecting in which the chances and difficulties are so great that only the most adventurous attempt it; the discovery of surface gold and the rush from all parts of the earth; the phenomenal finds and the invariably much greater proportion of failure; the tracing of the gold to its source and the discovery of some cubic acres, or it may be miles, of gold-bearing earth. Then at first only the deposits averaging several ounces to the ton are thought worthy of attention; but these rapidly give out, and attention is directed to the poorer and still poorer veins, while at the same time the steady progress and evolution of the pioneer camp, where often gold seems to be commoner than water, into the civilised community served with railways, electric power, and often elaborate water supply, cheapens the cost of extraction to such an extent that deposits averaging only a few grains to the ton can be made to yield a profit. Finally, we have the same inevitable end when science and organisation have done all in their power, and the remaining ore contains just so much gold as *not* to pay.

Let the case be stated a little differently. What would be the effect of the sudden discovery in any one place of some really large quantity of gold? There seems no doubt that utter chaos would ensue in the commercial world, which might involve before it was got under control a re-arrangement of the map of the world. Since nothing of the sort has ever happened, in spite of the most unprecedented struggles to that end, it is in accord with the principles of natural evolution to conclude that such a contingency probably violates some law of nature. Thus the gentlemen in charge of the national exchequer and of the Bank of England, who on a casual examination appear to be placing the most blind and implicit confidence on the future continuance of the existing order of things, are in reality secure in a fundamental if previously unrecognised law of nature. Eighteen months ago, after my visit to the gold deposits of Western Australia and New Zealand, and by the information which all concerned in the industry so readily placed at my disposal, I became convinced that in all probability gold, like radium, is at once the product of some other parent element, and is itself changing to produce "offspring" elements, so that its quantity, and hence its value, was fixed simply as the ratio of these two rates of change.

My experiments with gold have been both by the direct and indirect methods. The former have been dogged by misfortune and have so far been without result, while in the indirect experiments on ancient gold the results until now have been conflicting. Certainly some nuggets did not contain helium in appreciable quantities, while in others I did find a minute quantity of helium. This, however, was before the elaborate precautions afterwards employed had been adopted, and as I can now repeat the experiments with certainty as soon as occasion permits I am keeping a quite open mind. On the other hand, I have established to my own satisfaction that helium is an invariable constituent of native platinum in all the samples I have tried. The above reasoning, from rarity, after extended search, applies to platinum to a degree only less complete than in the case of gold.

The experiments with the other elements have not yet been proceeding long enough to have furnished results, but I have made a great many experiments with uranium and thorium in the attempt to detect directly the production of helium from these elements. These elements have been, in fact, the standards, for their rate of change is accurately known, and, assuming with Rutherford that the α particle is an atom of helium, may be expected to yield helium at a known rate. The methods of search have been perfected in the case of these two elements, and I am glad to be able to say that it is now only a question of time and patience before the rate at which helium is being produced from these two elements is accurately measured. On the other hand, if helium is not being produced, the experiments will indicate a maximum possible limit of the rate of production (set by the smallest quantity of helium detectable) far below the rate to be expected from theory. This method, which is, of course, applicable to any other element, would detect any other gas of the argon-helium family if produced. So far, however, I have only had one completely successful experiment with each element. In the case of uranium the result was positive, and indicated a rate of production of the same order as that required by theory. In the case of thorium, the experiment was of the nature of a blank test, and it proved that the rate of production is certainly not greater than ten times that required by theory.

Mr. Murray's letter induces me to put on record these imperfect results, and I do this the more readily as they may perhaps serve to emphasise and support his suggestion that experiments along the lines and on the scale he suggests should be carried out. But what laboratory in England could deal with ten tons of lead over a term of ten years?

After a year's work, I confess I am less hopeful than I was of the ability of the individual worker to carry out direct experiments in this subject of atomic disintegration. I wonder if the individual with his humble kilogram and his single lifetime is not starting on an almost forlorn hope, and is unduly and unnecessarily handicapped. Due consideration should be given to the supreme consequences that must follow from successful discoveries in this field. Not only is there to be considered the effect such results must exert on the whole trend of philosophic thought, but certain definite economic problems would be solved. For example, the proof of the disintegration of gold would reduce the doctrine of bimetallism and the theory of

currency to a branch of physical science, while in the mining industry the results would possess a fundamental significance. For the first time in the history of mineralogical chemistry it is possible, thanks to the researches of Boltwood, Strutt, and McCoy, to predict with considerable certainty the percentage of one element (radium) present if the percentage of another (uranium) is known; and one asks to what this discovery may not grow.

It seems to me that the individual and his single lifetime is too small a stake for the prize in view. Such a work should be national, and carried on from century to century if necessary; and what nation has such a right or such a duty as the one in which the subject of atomic disintegration originated? I confess to a feeling of impatience, to the sense of the inadequacy of the single lifetime, in my experiments on such small quantities of gold as I can purchase, when, disintegrating at the same rate, if disintegrating at all, tons of gold are lying useless in the national bank, their secret—possibly one that it much concerns the race to know—guarded from knowledge by every cunning invention that the art of man may devise. I confess to a sense of indignation that I should have to purchase for my experiments coins and other objects of known antiquity when within the walls of the National Museum lie—mere dead relics as they at present are—one of the finest collections in existence, capable of affording evidence perhaps of a longer history than any dreamed of by the antiquarian, and guarded by those who cannot interpret the cypher, and who, officially at least, are unaware of its existence. I confess to a feeling of misgiving in starting experiments where, on the scale possible to the individual, the chances are all against their yielding a positive result in a lifetime. Surely considerations of this character, the availability of the national resources and antiquities for the purpose of scientific investigations under due safeguards, and the provision for and care of experiments of long period with great quantities demanded by this new subject, are worthy of the attention of the nation, and of the British Science Guild as its newly formed adviser. Frederick Soddy.

The University, Glasgow, December 9.

The suggestion which Mr. Murray has put forward (p. 125) in explanation of the constancy of association of lead and silver has occurred to me also, and is indicated in an article which will probably appear shortly in the "Jahrbuch der Radioactivitat und Elektronik"; some calculations are contained therein which may be of sufficient interest to justify reproduction here.

Some recent experiments[1] have afforded evidence that the activity of the ordinary metals is caused by the emission of α particles. On the assumption that these α particles have an ionising power similar to that of those from radioactive elements, it appears that lead should emit less than one such particle per second. In order to find the maximum rate of change that we can attribute to this metal, we will assume that the emission of one such particle involves the breaking up of one atom of lead and the formation of one atom of silver; thus one atom breaks up per second. Now a gram of lead contains about 4×10^{21} atoms, and therefore to transform one ten-millionth part of the lead would require 4×10^{14} seconds or more than ten million years. Since it would be impossible to detect a smaller proportion than this by chemical tests, I fear that the experiment which Mr. Murray suggests is impracticable. The earth would probably have ceased to be a habitable globe by the time that the lead was ripe for examination; perhaps we may trust posterity to settle the matter with greater expedition!

But the slowness of the change in lead presents serious difficulties to the theory that the silver in galena is a disintegration product. Even so small a proportion as one in ten thousand ($3\frac{1}{2}$ ounces to the ton) would mean that the silver had been accumulating for a thousand million years—a period longer than that usually assigned as the age of the earth. But until we know more of the processes by which deposits of ore were formed, it is impossible to say whether the lead could have retained its silver through all the vicissitudes of its career. I believe that the silver cannot be separated from galena by any physical means; it may be so intimately associated that geological processes cannot affect it; but against this we have to set the fact that cerussite often contains much less silver than the galena from which it is obviously derived. But here chemical separation may have taken place involving the passage of the metals into solution.

There are problems connected with the "traces of impurity" constantly associated with certain minerals which await solution by some laborious chemist; it would be interesting to see whether there is any tendency to proportionality like that which holds between uranium and radium. But the absence of such a relation might be explained on the grounds that radio-active equilibrium had not yet been attained.

There is one other point to which attention may be directed. Rutherford has shown that the loss of heat from the earth by conduction would be compensated by the energy evolved by radium distributed throughout the mass of the earth in the ratio of 1 to 2×10^{13}; it appears that this amount of energy might be supplied by the disintegration of the actual constituents of the earth even if no radium were present. It is becoming clear that the older estimates of the age of the earth, based on physical data, are wholly erroneous; but if the radio-activity of all elements can be established rigidly, and the time constants of their decay measured with sufficient accuracy, it may be possible to use the evidence to which Mr. Murray has directed attention to gain some information as to the period that has elapsed since the solidification of the earth's crust. Norman R. Campbell.

Trinity College, Cambridge, December 10.

[1] The accounts of these should be included in an early number of the *Philosophical Magazine*.

In Nature, December 7, p. 125, Mr. Donald Murray suggests that the constant association of different elements arises from the slow transmutation of one into the other. The idea is certainly a reasonable one, and I presume has long been in the minds of all who have followed recent work. The writer discussed this question last year (*Chem. News*, 1904, lxxxix., 47, 58, 118), and arrived at Mr. Murray's opinion.

Now interest in the matter is reviving, perhaps I may be allowed to direct attention to this discussion.

Kiel, December 10. Geoffrey Martin.

Action of Wood on a Photographic Plate.

I have recently seen some photographic plates used at the last eclipse which have on them, not only pictures of the sun, but also pictures of the wood forming the dark-slides in which they had been placed.

At a former eclipse I understand a similar disaster occurred. It may, therefore, be well for me again to state that wood in contact with, or in near proximity to, a photographic plate, even in the dark, can impress upon the plate a clear picture of itself.[1] This action is much stimulated by high temperature and brilliant sunshine. It can, however, be stopped in several ways; probably the simplest one would be to make the slides of copper in place of wood. William J. Russell.

Davy-Faraday Laboratory.

Magnetic Storms and Auroræ.

The interesting paper by Dr. Chas. Chree in your issue of November 30 (p. 101) is inaccurate in one particular. He states that the storm of November 12 was not accompanied by auroræ. My friend Mr. John McHarg, of Lisburn, writes me that "it was fairly prominent, to be seen easily above the moonlight, the usual type, a steady glow brighter than the Milky Way, extending half round the horizon and fading off upwards at an altitude of 20°, or 30° in the west."

From that station auroræ were also observed on November 14, 15, 16, 17, 20, 21, 22, 23, 26, 27, and 30, and it is reported also that a bright crimson arch was seen on the early morning of December 1.

F. C. Dennett.

NOTES ON STONEHENGE.[1]

IX.—FOLKLORE AND TRADITIONS.

SO far in these notes I have dealt chiefly with stones, as I hold, associated with, or themselves composing, sanctuaries. We have become acquainted with circles, menhirs, dolmens, altars, viæ sacræ, various structures built up of stones. Barrows and earthen banks generally came afterwards.

The view which I have been led to bring forward so far is that these structures had in one way or another to do with the worship of the sun and stars; that they had for the most part an astronomical use in connection with religious ceremonials.

The next question which concerns us in an attempt to get at the bottom of the matter is to see whether there are any concomitant phenomena, and, if there be any, to classify them and study the combined results.

Tradition and folklore, which give dim references to the ancient uses of the stones, show in most unmistakable fashion that the stones were not alone; associated with them almost universally were many practices such as the lighting of single or double fires in the neighbourhood of the stones, passing through them and dancing round them; there were also other practices involving sacred trees and sacred wells or streams.

Folklore and tradition not only thus may help us, but I think they will be helped by such a general survey, brief though it must be. So far as my reading has gone each special tradition has been considered by itself; there has been no general inquiry having for its object the study of the possible origin and *connection* of many of the ancient practices and ideas which have so dimly come down to us in many cases and which we can only completely reconstruct by piecing together the information from various sources.

I now propose to refer to all these matters with the view of seeing whether there be any relation between practices apparently disconnected in so many cases if we follow the literature in which they are chronicled. We must not blame the literature since the facts which remain to be recorded now here, now there, are but a small fraction of those that have been forgotten. Fortunately, the facts forgotten in one locality have been remembered in another, so that it is possible the picture can be restored more completely than one might have thought at first.

It will be noted at once that from the point of view with which we are at present concerned, one of the chief relations we must look for is that of time, seeing that my chief affirmation with regard to the stone monuments is that they were used for ceremonial purposes at certain seasons, those seasons being based first upon the agricultural, and later upon the astronomical divisions of the year.

But in a matter of this kind it will not do to depend upon isolated cases; the general trend of all the facts available along several lines of inquiry must be found and studied, first separately and then *inter se*, if any final conclusion is to be reached.

This is what I now propose to do in a very summary manner. It is not my task to arrange the facts of folklore and tradition, but simply to cull from the available sources precise statements which bear upon the questions before us. These statements, I think, may be accepted as trustworthy, and all the more so as many of the various recorders have had no idea either of the existence of a May year at all or of the connection between the different classes of the phenomena which ought to exist if my theory of their common origin in connection with ancient worship and the monuments is anywhere near the truth.

This question of time relations is surrounded by difficulties.

I give in Fig. 23 the Gregorian dates of the beginning of the quarters of the May year, if nothing but the sun's declination of 16° 20′ N. or S., four times in its yearly path, be considered. These were:—

	May Year	Greek Calendar	Roman Calendar
End of Winter ... ... / Beginning of Spring ...	Feb. 4	Feb. 7	Feb. 7
,, Summer ...	May 6	May 6	May 9
End of Summer ... ... / Beginning of Autumn ...	Aug. 8	Aug. 11	Aug. 8
,, Winter ...	Nov. 8	Nov. 10	Nov. 9

In the table I also give, for comparison, the dates in the Greek and Roman calendars (p. 20).

There is no question that on or about the above days festivals were anciently celebrated in these islands, possibly not all at all holy places, but some at one and some at another; this, perhaps, may help to explain the variation in the local traditions and even some of the groupings of orientations.

The earliest information on this point comes from Ireland.

Cormac, Archbishop of Cashel in the tenth century, states, according to Vallancey, that "in his time four

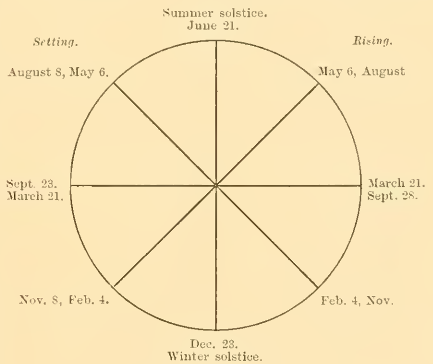

FIG. 23.—The farmers' and astronomical years.

great fires were lighted up on the four great festivals of the Druids, viz., in February, May, August, and November."[1]

I am not aware of any such general statement as early as this in relation to the four festivals of the May year in any part of Britain, but in spite of its absence the fact is undoubted that festivals were held, and many various forms of celebration used, during those months.

From the introduction of Christianity attempts of different kinds were made to destroy this ancient time system and to abolish the so-called "pagan" worships and practices connected with it. Efforts were made to change the date and so obliterate gradually the old traditions; another way, and this turned out to be the more efficacious, was to change the venue of the festival, so to speak, in favour of some Christian celebration or saint's day. The old festivals took no

[1] Continued from vol. lxxii. p. 272.

[1] Hazlitt, "Dictionary of Faiths and Folklore," under Gule of August.

account of week-days, so it was ruled that the festivals were to take place on the first day of the week; later on some of them were ruled to begin on the first day of the month.

When Easter became a movable feast, the efforts of the priests were greatly facilitated, and indeed it would seem as if this result of such a change was not absent from the minds of those who favoured it.

The change of style was, as I have before stated, a fruitful source of confusion, and this was still further complicated by another difficulty. Piers[1] tells us that consequent upon the change "the Roman Catholics light their fires by the new style, as the correction originated from a pope; and for that very same reason the Protestants adhere to the old."

I will refer to each of the festivals and their changes of date.

February 4.

Before the movable Easter the February festival had been transformed into Ash Wednesday (February 4). The eve of the festival was Shrove Tuesday, and it is quite possible that the ashes used by the priests on Wednesday were connected with the bonfires of the previous night.

It would seem that initially the festival, with its accompanying bonfire, was transferred to the first Sunday in Lent, February 8.

I quote the following from Hazlitt[2]:—

"Durandus, in his 'Rationale,' tells us, Lent was counted to begin on that which is now the first Sunday in Lent, and to end on Easter Eve; which time, saith he, containing forty-two days, if you take out of them the six Sundays (on which it was counted not lawful at any time of the year to fast), then there will remain only thirty-six days: and, therefore, that the number of days which Christ fasted might be perfected, Pope Gregory added to Lent four days of the week beforegoing, viz. that which we now call Ash Wednesday, and the three days following it. So that we see the first observation of Lent began from a superstitious, unwarrantable, and indeed profane, conceit of imitating Our Saviour's miraculous abstinence. Lent is so called from the time of the year wherein it is observed: Lent in the Saxon language signifying Spring."

Whether this be the origin of the lenten fast or not it is certain that the connection thus established between an old pagan feast and a new Christian one is very ingenious: 24 days in February plus 22 days in March (March 22 being originally the fixed date for Easter) gives us 46 days $(6\times7)+4$, and from the point of view of priestcraft the result was eminently satisfactory, for thousands of people still light fires on Shrove Tuesday or on the first Sunday of Lent, whether those days occur in February or March. They are under the impression that they are doing homage to a church festival, and the pagan origin is entirely forgotten not only by them but even by those who chronicle the practices as "Lent customs."[3]

Finally, after the introduction of the movable Easter, the priests at Rome, instead of using the "pagan" ashes produced on the eve of the first Sunday in Lent or Ash Wednesday in each year, utilised those derived from the burning of the palms used on Palm Sunday of the year before.

Further steps were taken to conceal from future generations the origin of the "pagan" custom due on February 4. February 3 was dedicated to St. "Blaze." How well this answered is shown by the following quotation from Percy.[4] "The anniversary of St. Blazeus is the 3rd February, when it is still the custom in many parts of England to light up fires on the hills on St. Blayse night: *a custom antiently taken up perhaps for no better reason than the jingling resemblance of his name to the word Blaze.*"

This even did not suffice. A great candle church festival was established on February 2. This was called "Candlemas," and Candlemas is still the common name of the beginning of the Scotch legal year. In the Cathedral of Durham when Cosens was bishop he "busied himself from two of the clocke in the afternoone till foure, in climbing long ladders to stick up wax candles in the said Cathedral Church; the number of all the candles burnt that evening was 220, besides 16 torches; 60 of those burning tapers and torches standing upon and near the high altar."[1]

There is evidence that the pagan fires at other times of the year were also gradually replaced by candles in the churches.

May 6.

The May festival has been treated by the Church in the same way as the February one. With Easter fixed on March 22, 46 days after Easter brought us to a Thursday (May 7), hence Holy Thursday[2] and Ascension Day. With Easter movable there of course was more confusion. Whit Sunday, the Feast of Pentecost, was only nine days after Holy Thursday, and it occurred, in some years, on the same day of the month as Ascension Day in others. In Scotland the festival now is ascribed to Whit Sunday.

It is possibly in consequence of this that the festival before even the change of style was held on the 1st of the month.

In Cornwall, where the celebrations still survive, the day chosen is May 8.

August 8.

For the migrations of the dates of the "pagan" festival in the beginning of August from the 1st to the 12th, migrations complicated by the old and new style, I refer to Prof. Rhys' Hibbert lectures, p. 418. in which work a full account of the former practices in Ireland and Wales is given.

The old festival in Ireland was associated with Lug, a form of sun-god. The most celebrated one was held at Tailltin. This feast—Lugnassad—was changed into the Church celebration Lammas—from A. S. hláfmaesse—that is loaf-mass, or bread-mass, so named as a mass or feast of thanksgiving for the first fruits of the corn harvest. The old customs in Wales and the Isle of Man included the ascent of hills in the early morning, but so far I have come across no record of fires in connection with this date.

November 8.

The fact that November 11 is quarter day in Scotland, that mayors are elected on or about that date, shows, I think, clearly that we are here dealing with the old "pagan" date.

The fact that the Church anticipated it by the feast of All Souls' on November 1 reminds us of what happened in the case of the February celebration, later I give a reference to the change of date; and perhaps this change was also determined by the natural gravitation to the first of the month as in the case of May, and because it marked at one time the beginning of the Celtic year.

[2] Under Ash Wednesday.
[3] Frazer, "Golden Bough," ii., 247 *et seq.*
[4] "Notes to Northumberland Household Book," 1770, p. 333.

[1] Quoted by Hazlitt.
[2] Much confusion has arisen with regard to the Holy Thursday in Rogation week because there is another Holy or Maundy Thursday in Easter week. Archæologists have also been often misled by the practice of many writers of describing the May festivals as midsummer festivals. The first of May, of course, marked the *beginning* of summer.

But what seems quite certain is that the feast which should have been held on November 8 on astronomical grounds was first converted by the Church into the feast of St. Martin on November 11. The "Encyclopædia Britannica" tells us

"The feast of St. Martin (Martinmas) took the place of an old pagan festival, and inherited some of its usages (such as the Martinsmännchen, Martinsfeuer, Martinshorn, and the like, in various parts of Germany."

St. Martin lived about A.D. 300. As the number of saints increased, it became impossible to dedicate a feast-day to each. Hence it was found expedient to have an annual aggregate commemoration of such as had not special days for themselves. So a church festival "All Hallows," or "Hallowmass," was instituted about A.D. 610 in memory of the martyrs, and it was to take place on May 1. For some reason or another this was changed in A.D. 834. May was given up, and the date fixed on November 1. This was a commemoration of all the saints, so we get the new name "All Saints' Day."

There can be little doubt that the intention of the Church was to anticipate and therefore gradually to obliterate the pagan festival still held at Martinmas, and it has been successful in many places, in Ireland, for instance; at Samhain,[1] November 1 "the proper time for prophecy and the unveiling of mysteries; . . . it was then that fire was lighted at a place called after Mog Ruith's daughter Tlachtga. From Tlachtga all the hearths in Ireland are said to have been annually supplied, just as the Lemnians had once a year to put their fires out and light them anew from that brought in the sacred ship from Delos. The habit of celebrating *Nos Galan-galaf* in Wales by lighting bonfires on the hills is possibly not yet quite extinct."

Here, then, we find the pagan fires transferred from the 8th to the 1st of November in Ireland, but in the Isle of Man this is not so. I will anticipate another reference to Rhys by stating that Martinmas had progressed from the 11th to the 24th before the change of style had brought it back, "old Martinmas," November 24, being one of the best recognised "old English holidays," "old Candlemas" being another, at the other end of the May year, which had slipped from February 2 to February 15 before it was put back again.

With regard to the Isle of Man Rhys writes[2] that the feast is there called Hollantide, and is kept on November 12, a reckoning which he states "is according to the old style." The question is, are we not dealing here with the Martinmas festival *not* antedated to November 1? He adds, "that is the day when the tenure of land terminates, and when serving men go to their places. In other words it is the beginning of a new year." This is exactly what happens in Scotland, and the day is still called Martinmas.

There is a custom in mid-England which strikingly reminds us of the importance of Martinmas in relation to old tenures, if even the custom does not carry us still farther back. This is the curious and interesting ceremony of collecting the wroth silver, due and payable to his Grace the Duke of Buccleuch and Queensbury, on "Martinmas Eve." The payment is made on an ancient mound on the summit of Knightlow Hill, about five miles out of Coventry, and in the parish of Ryton-on-Dunsmore. One feature about this singular ceremonial is that it must be observed before sun-rising. The money is now paid as a sort of highway rate for the privilege of using certain roads in the Hundred of Knightlow, and, according to the ancient charter, the penalty is a fine of twenty shillings for every penny not forthcoming, or the forfeiture of a white bull with red nose and ears. There are no defaulters nowadays, and if there were it would certainly be difficult, if not impossible, to find a beast answering the above description, as this breed of cattle has become extinct. When the short ceremony is over, those taking part adjourn to a wayside inn, and there with glasses charged with hot rum and milk they toast the Duke's health.

NORMAN LOCKYER.

[1] Rhys, "Hibbert Lectures," p. 514.
[2] "Celtic Folklore," p. 315.

AN AUSTRALIAN STORY BOOK.[1]

SHOULD any reader of NATURE desire to give a Christmas present to a boy or girl he might do much worse than buy Mrs. Jeanie Gunn's little book, but before parting with it he should himself look through it. The author has a great sense of humour, and seizes on salient features of native life and describes them in a few words; these gifts, combined with a real sympathy with the blackfellow, have enabled her to write a little book that is full of human interest. This is not an ethnographical treatise, and no matters are gone into in detail, yet the reader will learn somewhat of the life of Australian aborigines and of their relations with the white man, and if he should not acquire any deep knowledge he will have nothing to unlearn, and that is something to be thankful for.

A few examples culled at random will give a good idea of this most excellent little book.

"The blacks' sign language is very perfect. They have a sign for every bird, beast, fish, person, place and action. They have long talks without uttering a word. There are many times when a blackfellow must not speak, unless by signs. For instance, if he is mourning for a near relative, or has just come from a very special corrobboree. Often he must keep silent for weeks, and occasionally for months, and it is because of this and many other reasons that the sign language is so perfect. Everyone can speak it, and everyone does so when hiding in the bush from enemies, and then there is no fear of voices being heard."

"It is very wonderful, but then the blacks *are* wonderful. To have any idea of how wonderful they are, you must live among them, going in and out of their camps, and having every one of them for a friend. Just living in a house that happens to be in a blackfellow's country is not living among blacks, although some people think it is."

"I had plenty of Eau de Cologne, and used it freely. One day when Bett-Bett smelt it, as I was sprinkling it over my dress, she screwed up her little black nose, and after half-a-dozen very audible sniffs, said—'My word, Missus! That one goodfellow stink all right!'"

"Anyone can 'sing magic,' even lubras, but of course the wise old magic men do it best. It never fails with them, particularly if they 'sing' and point one of the special Death-bones or Sacred stones of the tribe. Generally a blackfellow goes away quite by himself when he is 'singing magic,' but very occasionally a few men join together, as they did in the case of Goggle Eye. . . . Of course the man who has been 'sung' must be told somehow, or he will not get a fright and die. There are many ways

[1] "The Little Black Princess: A True Tale of Life in the Never-never Land." By Jeanie Gunn. Pp. vii+107; illustrated. (London: The De La More Press, 1905.) Price 5s. net.

of telling him, without letting him know who has 'sung' him; but the man who leaves the bone about must, of course, be very careful to destroy his own tracks. Have you ever heard of faith-healing? Well, dying from bone-pointing is faith-dying! Goggle Eye, after he had found the bones lying about, knew exactly what was going to happen to him—and of course it did."

"You cannot change a blackfellow into a white man, if you try; you only make a bad, cunning, sly old blackfellow. I don't mean you can't make a blackfellow into a better blackfellow. I know that can be done, if he is kept a blackfellow, true to his blackfellow instincts." A. C. H.

FIG. 1.—Tree-burial, south of the Roper River. From "The Little Black Princess."

NOTES.

THE Nobel prizes in science have this year been awarded as follows: The prize for physics to Prof. P. Lenard, of the University of Kiel, for his investigations on kathode rays; the prize for chemistry to Prof. Adolf von Bayer, of the University of Munich, for the development in organic chemistry and chemical industry resulting from his works on organic colouring matters and hydro-aromatic compounds; the medical prize to Dr. Robert Koch, for his discoveries in connection with tuberculosis. The prizes, consisting of a sum of about 7700*l*., an illuminated diploma, and a gold medal with an appropriate inscription, were presented by King Oscar on December 10 at the annual ceremony in commemoration of the founder of the institution.

THE following note appeared in the *Times* of December 7:—Sir William Thiselton-Dyer, whose resignation of the post of director of the Royal Botanic Gardens at Kew is announced, has held that appointment since 1885, and for ten years—1875–1885—before his promotion he was assistant director. His successor, Lieut.-Colonel David Prain, had a distinguished university career at Aberdeen and Edinburgh before he entered the Indian Medical Service in 1884. Three years after his arrival in India he was nominated curator of Calcutta Herbarium; in 1895 he became professor of botany at the Medical College, Calcutta, and superintendent of the Royal Botanic Garden there, and in 1898 he was appointed director of the Botanical Survey of India. He is forty-eight years of age.

THE German Anatomical Society has decided to erect a memorial of its honorary president, the late Prof. Albert von Kölliker. The memerial will be erected in Würzburg, with which the famous teacher and investigator was intimately associated.

PROF. E. RIECKE, professor of experimental physics and applied electricity in the University of Göttingen, and also director of the Physical Institute, celebrated his sixtieth birthday on December 1; whilst Prof. R. Fittig, emeritus professor of chemistry of the University of Strassburg, celebrated his seventieth birthday on December 6.

THE committee appointed to carry the proposal of a memorial to the late Prof. Virchow into execution has now, we learn from the *British Medical Journal*, a sum of 4000*l*. at its disposal. Of this amount, 1800*l*. has been contributed by subscribers and 2200*l*. by the city of Berlin. Three prizes, of the value respectively of 150*l*., 100*l*., and 50*l*., are offered for the best design of a memorial. Drawings must be sent in before April, 1906.

THERE is a movement on foot in German chemical and technical circles to erect a statue in Freiburg, Saxony, to the memory of the late Prof. Dr. Clemens Winkler, who was professor in the Royal Mining Academy at Freiburg, and died in Dresden last year. The proposed memorial is to take the form of a large block of granite decorated with a medallion picture of the deceased investigator and a short account of his life's work.

THE French Académie des Inscriptions et Belles Lettres has elected Dr. Arthur Evans, keeper of the Ashmolean Museum, and Mr. Barclay, head keeper of the department of coins and medals in the British Museum, corresponding members of the academy.

THE thirteenth meeting of the International Congress of Prehistoric Anthropology and Archæology will be held at Monaco, under the patronage of Prince Albert the First, on April 16–21, 1906. Particulars as to the congress may be obtained from the general secretary, Dr. Verneau, 61 Rue de Buffon, Paris.

AT a meeting of the British committee for the Marseilles International Exhibition of Oceanography and Sea

Fisheries held last Friday, a central committee was nominated, consisting of Sir John Murray, K.C.B., the honorary president, Captain D. Wilson-Barker, Mr. W. E. Archer, Dr. H. O. Forbes, Mr. E. W. L. Holt, Dr. H. R. Mill, Dr. P. C. Mitchell, Prof. D'Arcy W. Thompson, C.B., Mr. J. W. Towse, and Dr. G. H. Fowler as honorary secretary.

A CONFERENCE on smoke abatement and an exhibition of smoke-preventive appliances, arranged by the Royal Sanitary Institute and the Coal-Smoke Abatement Society, were opened at the large hall of the Horticultural Society on Tuesday. At the conference parts of an address by Sir Oliver Lodge, who was prevented by illness from being present, were read by Sir William Richmond; and at the conclusion of the reading a paper entitled "Is London Fog Inevitable?" was contributed by Dr. W. N. Shaw.

THE dinner of the Institute of Chemistry was held on Monday at the Hotel Metropole, the president, Mr. David Howard, being in the chair. Responding to the toast of the institute, the president said that they had a very high ideal when they founded the institute; they wished to raise the standard of the chemist to something like the same level as that of the other learned professions. The position of the professional chemist was higher in England than it was anywhere else, and why? Because there was that independence of thought, that individual excellence and individual devotion to duty which was required in a true professional spirit.

THE seventeenth annual dinner of the Institution of Electrical Engineers took place on December 8 at the Hotel Cecil. A distinguished gathering assembled. Short speeches, in proposing and responding to the various toasts, were delivered by Mr. Babington Smith, the president (Mr. John Gavey), Sir Alexander Kennedy, F.R.S., Mr. E. Cunliffe Owen, Mr. Alexander Siemens, Mr. John G. Maydon, Mr. W. M. Mordey, Sir Alexander Binnie, and Dr. Budde, president of the Verband Deutscher Elektrotechniker of Berlin. Dr. Budde remarked that, speaking on behalf of his fellow electricians in Germany, he gratefully acknowledged the thought and the spirit expressed in the invitation to himself to be their representative as guest of the institution. Contact, he said, between the scientific and technical men of all countries cannot be too close. There are matters enough tending to separate nations, and therefore it cannot be too strongly pressed that research and intellectual labour form a tie which will always draw together the best spirits of the world, and must tend to promote international solidarity.

ON Saturday, December 9, a very interesting ceremony took place at the Royal Forest Hotel, Chingford, when a presentation was made to Mr. Wm. Cole, the founder of the Essex Field Club, in honour of the completion of his twenty-five years of service as hon. secretary, editor of the publications, and curator of the two museums founded by the club. At the instigation of the president, Mr. Miller Christy, a "recognition fund" was started a few months ago with Prof. Meldola as chairman, Mr. David Howard as treasurer, Mr. Christy as secretary, and a committee. The invitations issued on behalf of the movement were most cordially responded to, and the fund asked for was exceeded long before the subscription list was closed. At the dinner at Chingford Prof. Meldola presided and made the presentation on behalf of the subscribers, Mr. Cole and his brothers and sisters, all of whom had cooperated with him in carrying out the work of the club during the whole period of its existence, being present as the guests of the evening. The presentation took the form of an illuminated address and a purse. Among those who were present to support the chairman, and who bore testimony to the value of the work of the club and of the services of the hon. secretary and his family, were Mr. Victor Buxton, the High Sheriff of Essex, Mr. Christy and Mr. David Howard, the president and treasurer of the club, Mr. T. V. Holmes and Prof. Boulger, past-presidents, Mr. Gellatly, representing the verderers of Epping Forest, Messrs. W. Whitaker and Horace B. Woodward, hon. members of the club, Mr. W. M. Webb, representing the Selborne Society, and others. A very large number of appreciatory letters had also been sent, and were read from the chair, among the writers being the Countess of Warwick, Lord Rayleigh, Sir John Evans, Mr. E. N. Buxton, Profs. Ray Lankester, Marshall Ward, E. B. Poulton, and J. B. Farmer, Dr. Horace Brown, Mr. F. W. Rudler, Dr. J. C. Thresh, the chairman of the Essex County Council, the chairman of the Epping Forest committee, and all the past-presidents of the club other than those who were present. After the reading and presentation of the address by the chairman, and the handing of the purse by the treasurer, Mr. Cole returned thanks on behalf of himself and family. In the course of his remarks he laid emphasis on the services which the chairman of the evening had specially rendered to the club as their first and eighth president, and who had ever taken the keenest interest in their work. He produced a copy of the original inaugural address delivered by Prof. Meldola in 1880, and pointed out that the general policy of the club had been sketched out therein, and that it, with subsequent addresses, had been to them as models laying down the lines on which the work of their own and of all kindred societies ought to be conducted. In concluding, Mr. Cole also directed attention to several branches of work which he hoped to see the club take up in the future, among these being the establishment of a marine biological station, and the preservation, in connection with the photographic survey, of Essex folklore and dialects by means of phonographic records.

AT a meeting of the Institution of Civil Engineers on December 5, the Hon. Charles A. Parsons, C.B., F.R.S., and Mr. G. G. Stoney, in a paper read before the institution, traced the evolution of the steam-turbine from the time of Hero of Alexandria, following the chief steps in development that have led to the types in present use. After describing and discussing the chief characteristics of the three types of steam-turbine, which practically cover the whole field of useful turbine inventions, viz. the Parsons turbine, introduced in 1884, the De Laval turbine in 1888, and the Curtis turbine in 1902, the development of the Parsons turbine was dealt with. A good vacuum is required for the economical working of steam-turbines, and certain special conditions and arrangements must be observed in order to obtain a vacuum of $27\frac{1}{2}$ inches to 28 inches. An apparatus called a vacuum-augmenter has been designed by the authors, and consists of a steam jet placed in a contracted pipe between the condenser and the air-pump. With this apparatus, a total net reduction of steam-consumption of about 8 per cent. at full load has been obtained. Experience gained from cross-Channel steamers and yachts shows that the propellers of turbine vessels do not race in a heavy seaway, that the vessels maintain their smooth-water speed to a remarkable extent in heavy seaway, and that they start, stop, and manœuvre promptly.

IN a recent issue of *Scientific Investigations* (*Irish Fisheries*), 1904, Prof. G. H. Carpenter describes the

Pycnogonida, or sea-spiders, of the Irish seas, naming two new representatives of the group, each of which is figured.

"VOLITION IN MICRO-ORGANISMS" is the translation of the title of a paper by Mr. R. B. Mesén, published at San José, Costa Rica, apparently as the first part of a serial entitled *Publicaciones Nuevas por Contribucion de Amigos*. While admitting that the activity of such organisms is automatic, and due in the first instance to external stimulants, the author considers that such "automatomism" constitutes the basis of the human will, and that there is a complete gradation from the former to the very highest developments of the latter.

PERHAPS the most generally interesting article in the November number of the *American Naturalist* is one in which Mr. F. B. Loomis attributes the phenomenon in animals commonly known as "over specialisation" to "momentum." As examples of structures coming under the designation of over specialisation, the author cites the tusks of the sabre-toothed tigers, the radiolarian shell, the sutures of ammonites, sponge-spicules, and the horns of wild sheep, wapiti, and elk. A variation started in one particular line tends, in the author's opinion, to develop in that one direction; if the feature be harmful the development dies, otherwise it may continue *ad infinitum*. This theory of momentum, it is added, has not been credited with the importance to which it is entitled. Whether we are very much more forward for this supposed explanation of a very obvious feature in development may perhaps be open to doubt.

FROM the entomological division of the U.S. Department of Agriculture we have received a copy of a catalogue of exhibits of economic entomology at the recent St. Louis Exhibition, forming Bulletin No. 47. The whole exhibit was intended to bring into prominence the general scope of the work of the entomological division. Intimately connected with this is a memoir on the Mexican cotton-boll weevil, by Messrs. Hunter and Hinds, forming Bulletin No. 45 of the entomological division of the U.S. Agricultural Department. This weevil (*Anthonomus grandis*) has the evil distinction of having developed during the last twenty years from an insignificant into a notorious insect. In 1885 it was ascertained for the first time that this weevil attacked cotton in Mexico, and between that date and 1902 it crossed the Rio Grande into Texas, where it has since spread with extraordinary rapidity, and inflicted enormous losses on cotton-growers. After spreading for the first few years very quickly, it was checked for a time by unfavourable seasons, but meeting with suitable conditions in 1898 it soon colonised the greater part of the State. It was hoped that in ten years' time Texas would double its output of more than ten million bales of cotton, but this is now regarded as impossible.

IN the course of an article on western explorations for fossil vertebrates, published in the October number of the *Popular Science Monthly*, Prof. H. F. Osborn states that "it is an extremely slow and difficult matter to prepare a fossil, however carefully collected, for exhibition. It takes two years or more to work out the collections of a single season; the result is that most of our museums are collecting materials more rapidly than they can be worked. . . . With larger endowments or with special gifts these treasures could be more rapidly brought to light." It will not fail to be noticed that public exhibition of these wondrous fossils, when properly mounted, is regarded by American museum officials as a matter of prime importance. Those who pay for these institutions do not like the treasures hidden away for the sole benefit of the student.

A CHARACTERISTIC of modern American museums is formed by the restored models of extinct animals, of which there are scarcely any in the corresponding institutions of this country. A considerable number of such models were used by Prof. Osborn to illustrate his discourse on progress in mammalian palæontology during the last decade in America, delivered before the International Zoological Congress at Berne last year. The report of this lecture, published in the *Comptes rendus* of the congress, contains photographs of these models, one of the most spirited of which is herewith reproduced. In this instance, the restoration has been a comparatively easy task, as the animal belongs to an existing genus, but the workers under the author's direction have not hesitated to attempt to reproduce the external form of the Tertiary titanotheres and uintatheres, and even of the giant reptiles of the Jurassic and Cretaceous. It may be hoped that we shall ere long see some of these excellent restorations in our own museums. The author points out that there are three fossil elephants in America, viz. the mammoth (*Elephas primigenius*) in the far north, *E. columbi* (akin to *E. antiquus*) chiefly in the central States, and *E. imperator* (allied to *E. meridionalis*) in the south. Taken as a whole, Prof. Osborn's record of progress is little short of marvellous, and ought to make European palæontologists jealous, if jealousy could be supposed to exist in matters scientific.

FIG. 1.—Model of an Extinct Elephant (*Elephas imperator*).

THE report by Dr. Ashburton Thompson on the fourth outbreak of plague at Sydney in 1904 adduces further evidence on the part played by rats in the communication of plague to man. During the three last plague epidemics in this city, an epizootic among the rats was always found to precede the epidemic in man.

THE *Bulletin of the Johns Hopkins Hospital* for November (xvi., No. 176) contains the first of the Herter lectures on the contributions of pharmacology to physiology by Prof. Hans Meyer, the second part of the paper by Mr. Martin on the cause of the heart beat, and articles of considerable anatomical and medical interest.

THE October number of *Naturen*, published at the Museum, Bergen, contains an article by Prof. L. Kny on the sensitivity of plants, and a historical summary of the researches on the nature of alcoholic fermentation written by Mr. P. R. Sollied.

The American gooseberry mildew, *Sphaerotheca mors-uvae*, which was reported from Ireland in 1900, and from Russia in the succeeding year, has also appeared in Sweden. Dr. J. Eriksson, writing in Bulletin No. 87 of the experimental station of the Royal Agricultural College, traces the disease that developed in Karlshamm, in the south of Sweden, to bushes that had been imported from Denmark.

The monthly journal *Tropical Life* deals chiefly with tropical agriculture and commerce. Reference is made in the November number to two American machines recently brought out, the one a sugar-cane harvester, the other an auto-cottonpicker. The latter machine is provided with two long mechanical arms moving lightly in a universal joint; along each arm runs an endless belt studded with hooks. The arms are tilted to come in contact with the bolls, when the hooks pull away the whole mass, and the cotton passes along the belt to a receptacle. The possibility of utilising banana stems and trash for the manufacture of paper is discussed in view of the large amount of material that is produced in the cultivation of the fruit.

The cultivation of tomatoes under glass, with special reference to the value of pruning, is discussed in Bulletin No. 105 issued from the Hatch Experimental Station of the Massachusetts Agricultural College. The writer, Mr. G. E. Stone, advocates planting in beds rather than in pots, although the root restriction in pots favours early maturity. Pruning is said to promote early ripening and to produce increased size of fruit. There is some difference of opinion whether it is better to prune to one or three stems, but there is a general consensus in favour of cutting out the leader.

The report of the chief of the United States Weather Bureau for the fiscal year 1903–4 (pp. xxxix+381) contains, in addition to tables of observations and summaries at some 1650 stations, an interesting account of the very useful operations of that organisation. Weather forecasts for thirty-six and forty-eight hours in advance are issued for each State, besides special warnings of gales, cold waves, floods, &c. To mention one case only of the utility of the storm warnings—a hurricane which advanced from the West Indies destroyed property to the value of 100,000 dollars during its progress over Florida, but, owing to timely notice, comparatively little damage was done to vessels, as they remained in port in consequence of the warnings. Prof. W. L. Moore reiterates the hope that the time will come when it will be possible to forecast the weather for coming seasons, but that time has not yet arrived, and the officials of the Weather Bureau have been instructed to warn the public against imposition by long-range forecasters. A course of lectures on meteorology has been delivered by Prof. Abbe to students frequenting the Bureau, and we understand that this useful practice is now being carried out at our own Meteorological Office. The lectures present the results of work done by some of the ablest meteorologists in various parts of the world, and undoubtedly tend to excite greater interest in the science generally.

In the *Transactions of the American Mathematical Society* for October Mr. F. R. Sharpe discusses the stability of motion of viscous liquids. It was found by Reynolds in 1895 that for a liquid of density ρ and viscosity μ moving between two planes at distance $2b$ apart, the motion was unstable when $2b\rho U/\mu > 517$, while for a cylindrical pipe of radius a the critical velocity was given by $2ba/\mu = 1034$. Mr. Sharpe now obtains for the first case the constant 167 instead of 517, and for the second 470 instead of 1034.

In the *Smithsonian Miscellaneous Collections*, vol. xlvii., Prof. E. W. Scripture gives a first report of his studies on the construction of a vowel organ. The first experiments were made with reeds, but it was soon found necessary to replace these by rubber membranes held in various frames, and representing more closely the action of the human glottis. It is now possible to imitate all the vowels and their variations, and the remaining problem is to replace the rubber glottis by something that changes its form of vibration for different vowels and does not alter with time. When this can be done it will be possible to construct either a complete organ or a vowel register such as could be effectively used in church music. A register of one octave would require 124 vowel pipes.

In a note contributed to the *Journal of the Royal Microscopical Society* (first read before the New York Microscopical Society in April last) Mr. Daniel D. Jackson advances the view that the movements of diatoms are caused by the evolution of gas. This idea was first suggested to the author by noticing the behaviour of a lithia tablet in a glass of water: The bubbles of carbonic acid gas given off set up the exact motions in the tablet that have been so often described for the movements of diatoms —"a sudden advance in a straight line, a little hesitation, then other rectilinear movements, and, after a short pause, a return upon nearly the same path by similar movements." Mr. Jackson next made small models of diatoms of aluminium, 2 mm. thick, having longitudinal grooves resembling those of the diatoms. When placed in caustic soda these models not only reproduced the actual movements of the diatoms, but also gave rise to currents in the matter closely resembling those described by Prof. H. L. Smith as the result of observations made by placing indigo in the water.

We have received the *Transactions of the English Ceramic Society*, including the papers and discussions for the season 1904–5. It is satisfactory to note that the president, in the course of his address, considered that the scorn for technical instruction affected by pottery manufacturers in the past appeared to be dying out. Allusion was also made to the steps taken by the Joint Committee of Manufacturers of Staffordshire to foster research in pottery by offering prizes for original work bearing on certain subjects. The society appears to be in a prosperous condition, and its efforts are becoming more and more appreciated both at home and abroad. Amongst the various papers we notice an interesting contribution by the pottery instructor, Dr. J. W. Mellor, on crystallisation in pottery.

In No. 7 of the Bulletin of the Royal Academy of Belgium Prof. W. Spring describes experiments extending his well known work on the colour of natural waters. He comes to the conclusion that the calcium compounds present in natural waters have no colour peculiar to themselves, and hence are not responsible for the green tint of many waters containing them. This is probably due to the diffraction produced by minute solid particles, the presence of which can be demonstrated by an intensely luminous ray of light. Calcium salts really tend to conserve the pure blue colour of water by causing the elimination of ferric salts and humic materials. When a highly calcareous water is of a greenish hue it generally indicates that there is an equilibrium between the influx of brownish water containing humic material and ferric salts, and the purifying action of the calcium salts. In No. 8 of the same Bulletin Prof. Louis Henry discusses in a theoretical paper the properties of water and their relation to the formula H_2O. The physical properties point to a polymerisation of

the molecule, whilst a consideration of the chemical properties leads to the conclusion that the two atoms of hydrogen are functionally different, and that in reality water has a disymmetric formula.

A VERY interesting paper by M. T. Godlewski on certain radio-active properties of uranium is contained in No. 5 of the *Bulletin International* of the Cracow Academy of Sciences. A re-investigation has been made of the anomalous phenomena encountered by Meyer and Schweidler in studying the activity of uranium X. These authors had concluded that the decay curve of uranium X is not complementary to the recovery curve of uranium, but M. Godlewski considers that this only holds when the uranium nitrate containing the UrX is separated from its solution by crystallisation; when it is separated by evaporation to dryness at a temperature sufficiently high to remove the water of crystallisation, an abnormally high rate of decay is not observed. In fractionally crystallising uranium nitrate, uranium X, which is easily soluble in water, accumulates in the mother liquors; several crystallisations will completely deprive uranium nitrate of UrX. The author explains the increase of activity observed in the crystallisation of uranium nitrate as being due to an accumulation of UrX in the upper surfaces of the crystals; this appears to be confirmed by the observation that the activity of a crystal when turned over was found to be only one-third of the activity measured from the upper side. Experiments are brought forward to show that the first rapid decay of activity after crystallisation, which causes an uneven distribution of UrX throughout the plate, is due to the diffusion of UrX from the upper layers of the crystal, where it is more concentrated, to the lower, where the concentration is smaller. The view is held that the uranium X is dissolved in the crystals and the total mass of uranium in the form of a solid solution.

A SECOND and revised edition of the section of the report issued by the Engineering Standards Committee dealing with standard locomotives for Indian Railways has been published by Messrs. Crosby Lockwood and Son at 10*s*. 6*d*. net.

WE have received from Messrs. John J. Griffin and Sons, Ltd., a copy of their "H" list dealing with apparatus for use in the teaching of hydrostatics and pneumatics. The excellence of the illustrations and the lucidity of the brief descriptions make the catalogue a very serviceable one.

A CIRCULAR from the bio-chemical department of the University of Liverpool announces that the first number of a new periodical—the *Bio-Chemical Journal*—will be issued in January. Contributions are invited, dealing with all portions of the subject of bio-chemistry in its widest sense. The journal will be issued monthly, in so far as material is available.

THE University of Chicago Press has published a second edition of Dr. C. J. Chamberlain's "Methods in Plant Histology." The first edition of the book was reviewed in our issue for November 28, 1901 (vol. lxv. p. 75). The new issue contains both alterations and additions; and some of the improvements suggested in the review referred to have been made.

IN noticing the illustrated catalogues of makers of scientific apparatus in this country from time to time, we have directed attention to the excellence of the illustrations accompanying the descriptions of the different instruments. A revised price-list of microscopes and accessories which has been received from the Bausch and Lomb Optical Co., Rochester, N.Y., is another instance of a carefully arranged and admirably illustrated catalogue. The catalogue provides information concerning microscopes made by this firm suitable for general laboratory work, advanced work, bacteriology, photomicrography, and a physician's needs. The necessary accessories are detailed fully, and clear descriptions make their special characteristics easily understood. The sole representatives of the company in this country and the colonies are Messrs. A. E. Staley and Co., 19 Thavies Inn, Holborn Circus, E.C.

OUR ASTRONOMICAL COLUMN.

ANOTHER NEW COMET, 1905*c*.—A telegram from the Kiel Centralstelle announces the discovery of a new comet, by Prof. Giacobini, of the Nice Observatory, on December 6·080.

At 16h. 53·7m. (Nice M.T.) the comet's position was

$$R.A. = 14h.\ 21m.\ 39{\cdot}4s.,\ dec. = +20^\circ\ 59'\ 29'',$$

and subsequent observations showed that its daily movement in R.A. amounted to $+1^\circ\ 08'$ ($= +4m.\ 32s.$) and in dec. to $-0^\circ\ 26'$.

From the above it is seen that, when discovered, the comet was about 10m. east and $1^\circ\ 15'$ north of Arcturus, and that it is apparently travelling slowly towards the constellation Serpens.

A second telegram from Kiel announces that the comet was observed at the Lick Observatory on December 8. The position at 17h. 16·5m. (Lick M.T.) was determined as $R.A. = 14h.\ 32m.\ 58s.$, $dec. = +19^\circ\ 55'\ 36''$.

Circular No. 82 from Kiel states that the following elements and ephemeris have been computed by Mr. Morgan (Glasgow, Mo.) from observations made on December 6, 7, and 8, and communicated to the Centralstelle by Prof. E. C. Pickering:—

Elements.

T = 1906 January 16·20 (G.M.T.).

$$\left.\begin{array}{l} \omega = 213^\circ\ 56' \\ \Omega = \ \ 93\ \ 21 \\ i = \ \ 44\ \ 23 \end{array}\right\} 1905{\cdot}0$$

$$q = 0{\cdot}0928$$

Ephemeris 12h. G.M.T.

1905		α h. m. s.		δ ° ′		Brightness
Dec. 14	...	15 1 28	...	+17 1		
18	...	15 24 56	...	+14 22		
22	...	15 50 48	...	+11 13	...	4·22

The computed brightness for December 10 was 1·66, the brightness at time of discovery being taken as 1·0.

COMET 1905*b*.—A number of observations of comet 1905*b* (Schaer's) are recorded in No. 4057 of the *Astronomische Nachrichten*.

Using the Bruce telescope, and exposing for fifty-five minutes, Prof. Wolf photographed the comet on November 21, and obtained an image which showed the object to be unsymmetrical. A fine, faint tail was seen to issue from the coma in a position angle of 92°, reckoning from the direction of the comet's path. This tail was curved, with the concave side preceding, and at a distance of 22′ from the nucleus it was broken, the second part having a slightly different direction to the first.

On November 20 Prof. Wolf was able to see the comet with the naked eye, and estimated its magnitude to be about 5·5. On November 21 he found it to be about 6·3m., and on November 24 observed that it had decreased to 7·0.

The ephemeris calculated by Herr M. Ebell gives the position of this comet on December 15 as

$$\alpha = 23h.\ 32m.\ 16s.,\ \delta = -10^\circ\ 30'{\cdot}5,$$

and its brightness as about 0·04 of that at the time of discovery.

ORBITAL ELEMENTS OF TWO METEORS.—From a number of observations of a meteor which was seen on August 3 Dr. P. Moschick, of Heidelberg, has calculated the radiant point, the earth point, the velocity, and the height of the meteor, and also the elements of its orbit. For the apparent radiant he obtained $\alpha = 317° 56'$, $\delta = -11° 54'$, and for the mean velocity 47.93 ± 8.37 km. per second, the probable value for the absolute velocity being 52·74 km. per sec. The elements show the orbit to be hyperbolic, and the meteor's motion in the orbit to be direct.

A second meteor was seen by numerous German observers on September 28, and Dr. Moschick has treated the observational results similarly. For the position of the radiant point he obtained $\alpha = 354° 54'$, $\delta = +22° 40'$, and therefore concluded that the object observed was a Pegasid. The relative and absolute velocities were respectively 21·51 and 36·4 km. per second, and the calculated elements show that the meteor moved, with a direct motion, in an elliptical orbit (*Astronomische Nachrichten*, No. 4057).

MAGNETIC DISTURBANCE DURING THE RECENT AURORAL DISPLAY.—In a paper communicated to the Paris Academy of Sciences, M. Th. Moureaux states that a strong magnetic disturbance took place about 9 o'clock on November 15, coinciding, in point of time, with the exceptionally fine auroral display which was so generally observed. From 8h. 59m. to 9h. 9m. (Paris M.T.) the declination, which was already below the normal, diminished by 34′, and then quickly recovered, increasing 42′ between 9h. 9m. and 9h. 24m. The horizontal and vertical components were simultaneously affected in the opposite direction. Similar disturbances took place on November 12. Numerous small groups of sun-spots were on the solar disc during this period, and the first large group seen in October, now much scattered and diminished, was due to cross the central meridian on the evening of November 13, during its second rotation (*Comptes rendus*, No. 21).

THE ZODIACAL LIGHT TO THE NORTH OF THE SUN.—Whilst in Switzerland recently, Prof. Newcomb ascended the Brienzer Rothorn in order to observe, if possible, the extension of the zodiacal light in the north and south direction. He found that the light was bright enough to be seen at a distance of 35° from the sun in the direction of the solar axis, and he assumes that it extends equally on both sides. Prof. Newcomb therefore suggests that the zodiacal light shall in future be described "as a luminosity surrounding the Sun on all sides, of which the boundary is nowhere less than 35° from the Sun, and which is greatly elongated in the direction of the ecliptic" (*Astrophysical Journal*, No. 3, vol. xxii.).

CANADIAN ELECTRIC POWER STATIONS AT NIAGARA.

ON January 2 of this year, in the power house of the Canadian Niagara Power Company, on the Canadian side at Niagara, the largest units used in the development of water-power were started. This great power house is situated in Victoria Park, and all the work of development is done under consent from the Government of the Province of Ontario and the commissioners of the park.

Fourteen years ago ground was broken on the New York side at Niagara for a power development by means of a wheel-pit and tunnel. The 105,000 horse-power thus developed has been a great inspiration to the growth of the American city, and Canadians looked forward to the time when they should profit by a similar development. Now their hopes are being realised, for three strong companies are actively at work on the Canadian side developing power from the water that speeds toward the Horseshoe or Canadian Fall. It was in 1892 that the Canadian Niagara Power Company secured its first rights to develop power in Canada, and since then it has paid the park commissioners more than 225,000 dollars in the retention of its privileges, while its first horse-power was developed on the date above mentioned.

The Canadian Niagara Power Company is allied to the Niagara Falls Power Company of the New York side of the river, but in its Canadian development it has given men of science and electrical engineers the most wonderful installation to study yet known in the field of any water power development. In the big power houses on the New York side the unit of development is 5000 horse-power, but on the Canadian side the unit is 10,000 horse-power. It was in 1890, at a meeting of the International Niagara Commission, held in London, that a unit of 5000 horse-power was adopted for the development on the American side at Niagara.

Ten years have elapsed since Rudolph Baumann, a Swiss engineer, turned the wheel that started the first 5000 unit on April 4, 1895, and since that day the installation has been doubled in size and output capacity, and is in every way a success. Now comes Canadian Niagara with its units of 10,000 horse-power, the largest in the world. Mr. William H. Beatty, of Toronto, Ontario, who is president of the Canadian Niagara Power Company, turned the small wheel that controls the flow of water from the penstocks to the turbines, and as he admitted the flood of water the monster generator began to revolve, and within a few minutes was making 250 revolutions a minute, the speed at which it is to be steadily operated. Unit No. 2 was also started, making 20,000 horse-power available in the

FIG. 1.—Site of the Power House of the Ontario Power Co., showing its nearness to the Horseshoe Fall.

station, and by May 1 three additional units of the same size were ready to run, giving off a total of 50,000 horse-power from the five machines. In all, eleven units will be installed in this station, so that its final output will be 110,000 horse-power, or 5000 horse-power more than is available from the twenty-one machines in the two power houses of the Niagara Falls Power Company on the American side of the river.

In the wheel-pit and tunnel method of developing power at Niagara, a great slot, several hundred feet long, is excavated in the earth to a depth of about 180 feet and 21 feet wide. From the bottom of the wheel-pit a tail race or tunnel is driven through solid rock a distance of 2200 feet to the lower river or gorge. This tunnel is built in the form of a horseshoe, and is about 20 feet wide by 25 feet high. It is lined from end to end with vitrified brick and concrete, while the wheel-pit is also carefully lined. From the upper river a canal of short length diverts water from the main stream to a forebay at one side of the big power house. Near the bottom of the wheel-pit the turbines are installed, and these are connected to the generators in the power station over the wheel-pit by vertical shafts or tubes. From the forebay to the turbines penstocks 10 feet in diameter run to the turbines, and as

the gates are raised the water pours from these penstocks into the wheels that give motion and life to the big generators. As the water passes through, or is discharged from, the turbines, it falls into the tunnel, and then flows through this tail race to the lower river and gorge. It is diverted from the main stream but a very few minutes, but in that time it serves to aid man in gaining control of thousands of electrical horse-power.

It is agreed between the power companies and the commissioners of Victoria Park that all power generated in the park limits must be transmitted outside the park boundaries for application and use, and so the electric current from the station referred to will pass to a transformer station not far distant, where, for transmission purposes, it will have its voltage raised to 40,000 or 60,000 volts, in order that it may successfully and economically be sent to Toronto and other distant places to meet the demand for electric power from Niagara. Toronto has long been anxious to be connected by a transmission line with the power development at the falls, and now a line for transmission purposes has been about completed, so that electric current from the generators in the station of the Canadian Niagara Power Company may be used in the

FIG. 2.—Power House of Canadian Niagara Power Co., being erected over the wheel-pit.

operation of the trolley cars and lighting systems of the Canadian city nearly 90 miles away from Niagara.

The Electrical Development Company of Ontario, Ltd., is also constructing a wheel-pit and tunnel power development in Victoria Park. The works of this company will be a short distance above the site of the development of the Canadian Niagara Power Company, but, for all this, the tunnel it is building will be slightly shorter than the tunnel of the company last named, because it will run right under the river-bed, over which the upper rapids toss, to a point behind the falling sheet of water of the Horseshoe Fall, where it will empty into the lower river. From the bottom of this wheel-pit there will be two short lateral tunnels that will carry the water from the pit to the main tunnel at a point 165 feet from the bottom of the slot. This company projects a development of about 125,000 horse-power, and the machinery it will instal will command general attention.

The Ontario Power Company is another concern that has secured a franchise for the development of power in Victoria Park. Its method of development will be quite different from that of the other two companies referred to. Its power house, a concrete and iron structure, has been built at the water's edge, in the gorge, a short distance below the Horseshoe Fall, and water will be carried to it by penstocks concealed from view in tunnels that have been driven through the rocky bank from a spillway or open relief on top of the bank. From this spillway great steel flumes will extend to the forebays, which are situated far up the river. There will be three of these steel flumes, each 18 feet in diameter and more than 6000 feet long. Each will divert 3900 cubic feet of water every second, which is an amount estimated to be sufficient to develop 60,000 electrical horse-power in the station at the water's edge. Thus from the three steel flumes and the water supply thus afforded, no less than 180,000 horse-power is to be developed. This power will pass from the generators to a transformer station located on the bluff in the rear of Victoria Park more than 250 feet above the power house, and more than 550 feet back from it.

ORRIN. E. DUNLAP.

INVESTIGATION OF THE UPPER AIR.

THE subjoined announcement has been received from the director of the Meteorological Office.

In response to representations from various quarters, the Meteorological Committee has assigned from the Parliamentary grant under its control a sum for promoting the investigation of the upper air by kites and other means.

The immediate objects in view are:—(1) To establish an experimental station where kite ascents and other experimental investigations can be carried out, especially on the days selected for international cooperation. (2) To develop and extend the instrumental equipment, so that facilities may be afforded for the cooperation of other observers upon sea or land. (3) To provide for the publication of the observations in combination with those of other countries, by a contribution to the cost of the international publication undertaken by the president of the International Commission for Scientific Aërostation, Prof. H. Hergesell, of Strassburg.

Mr. W. H. Dines, F.R.S., has undertaken the direction of the operations for the Meteorological Office. His experiments for the office are carried on at his house at Oxshott.

An endeavour will be made, with fair prospect of success, to enlist the cooperation of marine observers in correspondence with the office. Captain A. Simpson, of the S.S. *Moravian*, has already expressed his willingness to make a trial of this method of extending our knowledge of marine meteorology as soon as the necessary gear and instruments can be supplied.

It is hoped that through the assistance of others who are interested in such investigations, and have at their disposal the means of carrying them out, an effective scheme for the investigation of the upper air may be set on foot. Lieut.-Colonel J. E. Capper, C.B., R.E., of the Aldershot Balloon Companies, has already facilities for such purposes, and will take part; Mr. G. C. Simpson, lecturer in meteorology in the University of Manchester, is making arrangements for occasional observations on the Derbyshire hills; Mr. C. J. P. Cave, who has already made some interesting kite ascents in Barbados, has provided himself with the necessary equipment for experiments at Ditcham Park; and Mr. S. H. R. Salmon has arranged a station on the Downs near Brighton, and carries out ascents on the international days.

There is, accordingly, a prospect of an effective investigation being commenced.

BOTANY AT THE BRITISH ASSOCIATION.

THE president, Mr. Harold Wager, F.R.S., dealt in his address, which was delivered at Johannesburg, with some problems of cell structure and physiology. The text of this address has already appeared (September 21) in NATURE.

As was to be expected, there were fewer papers than usual this year in Section K, and of these relatively few were of a purely technical nature, the majority being either general accounts of recent work or else papers which possessed some special local interest.

General Papers.—Prof. R. W. Phillips opened the pro-

ceedings at Cape Town by delivering a semi-popular lecture on recent advances in our knowledge of seaweeds. Dealing first with the attached shore vegetation, the lecturer pointed out that, with the exception of a very few phanerogams, this consists entirely of blue-green, green, red, and brown algæ. In the red algæ the most important recent work is that of Oltmanns, who has shown, in opposition to the view maintained by Schmitz, that no real nuclear fusion takes place in the auxiliary cells. In the brown algæ Williams's work on the Dictyotaceæ has considerably modified the views previously held regarding them. Not only has he discovered motile antherozoids in this group, but his work on their cytology points to the existence of a definite alternation of generations. Farmer and Williams had shown that in the Fucaceæ the reduction of chromosomes takes place at the origin of the oogonium. In Dictyota, however, as originally shown by Mottier, and since confirmed by Williams, the reduction division occurs in the mother-cells of the tetraspores. There would thus appear to be in this plant two generations, precisely similar in their external morphology, but fundamentally distinct in respect of the number of chromosomes in the dividing nucleus. Our knowledge of the floating oceanic vegetation has been greatly extended by the members of the German plankton expedition, and other workers. The lecturer dealt with the distribution of this floating vegetation in the surface waters of the globe, and described some of the adaptations which prevent rapid sinking of the minute forms composing it.

Mr. R. P. Gregory discussed some of the problems of heredity. He first gave a general account of Mendel's principles of heredity, referring to some of the more recent work on Mendelian lines. He then dealt particularly with some new experiments conducted by Mr. Bateson and himself, on the inheritance of heterostyly in Primula. Although certain irregularities were observed, on the whole the characters of long and short style were inherited in the usual Mendelian ratio, the short style being dominant, the long recessive. Further experiments, conducted in the hope of throwing light on the fact, observed by Darwin, of the relative infertility in "illegitimate" as compared with "legitimate" crosses in Primula, were inconclusive.

Prof. F. E. Weiss contributed a paper on the value of botanical photographs. He pointed out that the mapping of the plant-associations of any given district, and the detailed study of the ecological factors concerned, can be most usefully supplemented by good photographs showing the general aspect and distribution of the vegetation. It is important to have, not only general photographs of various plant-associations, but also photographs of the different members of such associations. Plant photography can also be usefully employed in morphological, pathological, and other studies. The truth of the author's remarks was forcibly illustrated by a series of beautiful lantern slides. Two committees are now at work collecting botanical photographs and rendering them available for teaching and other purposes. One, recently established for the survey of British vegetation, is concerning itself with British ecological photographs; the other, the British Association committee for the registration of photographs of botanical interest, has adopted a wider scheme, and is anxious to receive help from scientific photographers in all parts of the world.

An interesting discussion took place on educational methods in the teaching of botany. The president (Mr. Harold Wager, F.R.S.), who opened the discussion, was of opinion that the methods usually employed, both in universities and schools, neither develop real interest in the subject nor afford an adequate training in scientific method. He emphasised the importance of basing all courses of botanical teaching on practical work, both observational and experimental, such work to be carried out by the students themselves. Lectures should be rather of the nature of discussions upon the facts learned during practical work than merely informational. A good deal of faulty educational method is due to the domination of examinations. It is almost impossible for satisfactory work to be done if teachers are compelled to follow set syllabuses, which are generally so extensive as to leave little room for originality on the part of the teacher.

Several speakers agreed with the general conclusions of the president, but Mr. A. C. Seward, F.R.S., and Prof. Douglas Campbell were inclined to lay more stress on the importance of lectures, particularly where advanced students are concerned.

Miss Lilian Clarke contributed to the discussion a most interesting account of her methods of teaching botany in the James Allen School for Girls at Dulwich. She gives no set lectures, but the girls make observations and conduct experiments, not only in the school garden, where each girl has charge of a plot, but also in the laboratory. The latter has been designed so as to admit as much light as possible; it can also be kept at a constant temperature, so that practical work on living plants can be carried on at all seasons of the year.

South African Botany.—Mr. A. C. Seward, F.R.S., in discussing the fossil floras of South Africa, gave a general account of the plants characteristic of the Lower Karroo, Stormberg, and Uitenhage series. He laid stress on the need for further field work, as more material, particularly petrified specimens for microscopical examination, is badly needed to render our knowledge of these floras more complete.

Prof. A. Engler and Dr. R. Marloth presented important papers on the floras of tropical Africa and South Africa respectively.

Prof. Engler dealt with his subject largely from the ecological point of view. Discussing first the meteorological conditions of tropical Africa, he pointed out that in every tropical country, where the altitude of the land surface varies from sea-level to high mountains, practically the same plant-formations can be distinguished, though, of course, their systematic composition may be very different in different cases. The author then enumerated the various halophilous, hygrophilous, xerophilous and other formations, with their subdivisions, finally discussing the affinities of the flora as a whole. The dominant element of the flora is one peculiar to tropical Africa, the plants composing which are more nearly related to those of India and Madagascar than they are to those of tropical America. But besides this native element, we find in tropical Africa other elements. Thus in the hygrophilous formations of East Africa, Indian and Madagascan elements abound, while in those of West Africa a distinct tropical American element is found. A South African element is present, particularly in the shrub-formations of Angola and East Africa; a Mediterranean element in the north-east, especially in Somaliland; and lastly, in the high mountains, many species belonging to a boreal element are found. From the entire absence on these mountains of many groups characteristic of northern regions, Prof. Engler concludes that such northern forms as are here found have entered by immigration, and are not the remnants of a once widely spread Old World flora.

The botanical regions proposed by Dr. Marloth in his paper on the phyto-geographical subdivisions of South Africa are somewhat similar to those suggested by Bolus, Engler, and others, though differing in detail. The two main divisions, very unequal in size, are A, the Cape province, characterised by many endemic plants of more or less south temperate affinities, and B, the palæo-tropical province. The latter is again subdivided, according to ecological conditions and floral constituents, into (1) the grass-steppe regions, including the Bush-veld, High-veld, Kalahari, and the Caffrarian countries; (2) the central districts of Cape Colony, including the Karroo, the Karroid plateau and Little Namaqualand; (3) the western littoral; (4) the forests of the south coast; (5) the south-eastern coast belt.

Mr. J. Burtt-Davy contributed a paper on the climate and life zones of the Transvaal. He divides the Transvaal, according to altitude and climate, into three zones, which he terms the High, Middle, and Low Veld respectively. Each is characterised, not only by its native vegetation, but also by the crops it is capable of producing.

Mr. F. B. Parkinson gave an interesting account of irrigation farming as carried on at the Orange River farm at Baviaankrantz. To raise the water, chain and bucket pumps are employed, working in shafts sunk at a sufficient distance from the river to be above flood-level. The shafts are supplied with water from the river by means of 10-inch syphons. By judicious watering, winter cereal crops, and

summer crops of potatoes, peas, &c., can be profitably grown.

Mr. T. R. Sim discussed the distribution of South African ferns, and pointed out that the recent opening up of the Orange River Colony, the Transvaal, and Rhodesia has resulted in the filling up of many gaps in our knowledge of this subject.

Dr. Schönland gave a survey of our knowledge of South African succulent plants, chiefly from the historical and systematic points of view.

A paper was also contributed by Mr. J. Medley Wood on the indigenous plants of Natal.

Technical Papers.—Among these may be mentioned an interesting note by Dr. Horace T. Brown, F.R.S., on the dissipation of absorbed solar radiation by xerophilous plants. He pointed out that in ordinary foliage leaves the amount of heat necessary to vaporise the water of transpiration is so considerable that such a leaf may be subjected to intense solar radiation without acquiring a temperature of more than a very few degrees above that of the surrounding air. In xerophilous plants, however, transpiration is at a minimum, and therefore some other method of guarding against the risk of dangerously high temperatures is necessary. According to the author, this is to be found in the loss of heat due to thermal emission. Experiments have been conducted by him (in collaboration with Dr. W. E. Wilson) which show that a powerful cooling effect is produced by the high thermal emissivity of a leaf surface, even when transpiration is completely in abeyance.

Prof. H. H. W. Pearson communicated an interesting account of his investigations into the development and germination of the spores of Welwitschia. The results obtained show that some of the current views of the relationship of this extraordinary plant to the other genera of the Gnetaceæ must be considerably modified.

Prof. Douglas Campbell described the prothallium and reproductive organs of *Gleichenia pectinata*, and directed attention to the similarity that exists between them and those of Osmunda.

Prof. M. C. Potter presented two papers. In the first an account was given of some experiments which showed that amorphous carbon can be slowly decomposed by the agency of a soil bacterium, with the evolution of carbon dioxide.

The second dealt with the healing of parenchymatous tissues in plants. According to the author, the first step in this process (prior to the formation of cork) is the closing of the intercellular spaces by the formation of a "wound-gum" similar to that described by Temme in wounded xylem vessels. Thus the increased rate of gaseous interchange caused by the wound is very soon checked.

Mr. I. B. P. Evans, in a paper on infection phenomena in the Uredineæ, said that it is quite possible to identify different species of Puccinia by the shape of their infection vesicles.

Dr. G. Potts contributed a paper on the action of calcium compounds on *Plasmodiophora Brassicae* ("finger and toe"). Experiments show that an acid soil encourages the growth of the parasite, while alkaline substances inhibit it.

A most interesting feature of the Cape Town meeting was afforded by a fine collection of native plants, brought together with considerable trouble by Dr. Marloth. These included a number of the more striking succulents from the Karroo region, and also a great many plants from the south-west district of Cape Colony. The latter were, for the most part, in flower, the heaths and the Iridaceæ in particular presenting a beautiful blaze of colour. Dr. Marloth also exhibited a number of ecological photographs taken in various parts of Cape Colony.

But, apart from the meetings themselves, the over-sea botanists found considerable opportunities of observing the vegetation of the various districts passed through during the tour. It is true that much of the travelling was hurried, but even when passing rapidly through a new country a botanist is able to gather valuable impressions of the general facies, &c., of the vegetation.

At the Cape, though the season was still early spring, a considerable number of plants were in flower. Table Mountain and the slopes of the Lion's Head were explored so far as time permitted, and many plants characteristic of the Cape Peninsula flora were observed. Some of the most striking of these were plants belonging to the families Ericaceæ, Proteaceæ, and Restiaceæ.

Several members of Section K visited the Karroo, and spent some days in examining the many curious xerophilous desert plants to be found there.

In the Transvaal and elsewhere little or no rain had fallen for some five months before the visit of the association, and in consequence the country presented a very parched and brown appearance, except where irrigation had resulted in vivid patches of green crops, or groves of Eucalyptus trees had been planted. The latter, as well as other Australian plants, have been extensively imported, and promise to become of considerable economic importance in South Africa.

A very striking feature of the bush vegetation in various parts of the Transvaal was the extraordinary prevalence of parasitic Loranthaceæ, many of the acacia and other trees being loaded with the parasites.

At Pretoria the Government experimental grounds were visited, the visitors being received by Mr. Smith, the Director of Agriculture, and Mr. Burtt-Davy. Extensive experiments are being at present carried on here with a view to the introduction of new grasses to improve the pasturage of the Transvaal. Other useful introduced plants include several species of Atriplex (the Australian "saltbush"). As these plants are markedly xerophilous, and at the same time good fodder plants, they will probably prove very useful in a climate such as that of the Transvaal.

The agricultural department in Pretoria had also arranged an exhibition illustrative of the vegetable products of the Transvaal.

Mr. Burtt-Davy arranged a special botanical excursion to the Magaliesberg, where the "Wonderboom," an exceedingly fine specimen of *Ficus cordata*, was visited.

Other areas of botanical interest passed through included the High Veld, the Bush Veld, the teak forest of Rhodesia, and the luxuriant so-called rain-forest immediately surrounding the Victoria Falls.

PRIZE SUBJECTS OF THE INDUSTRIAL SOCIETY OF MULHOUSE.

THE Industrial Society of Mulhouse has issued its programme of the prizes to be awarded by the society during the year 1906; excluding the subjects which are of a purely local or technical character, the following are the principal prizes open to competition to all nations.

In the section of chemistry medals of honour are offered for a memoir on the theory and manufacture of alizarin-red by the rapid process, for a synthesis of the colouring matter of cochineal, for a research on cochineal carmine, for an investigation of the colouring matter of cotton, of the transformation of cotton into oxycellulose, or of the composition of aniline blacks; also for a research on the chemical changes of wool under the action of hypochlorites or chlorine, for a synthesis of a natural dye, for a theory of the manner of formation in nature of any organic substance, or for a chemical study of the fat of Turkey-red. Several medals will also be awarded for special chemical studies of mordants and their action, for the production by artificial means of certain dyes, and for practical methods of fixing certain dyes to the fibre. A method of manufacturing carbon tetrachloride at a price such as will enable it to compete with carbon bisulphide and benzene is also required. A sum of 500 francs to 1000 francs will be allotted to the best compilation of the densities of inorganic and organic substances in the solid state and in cold saturated solution. Medals will be given for the production of substances capable of taking the place of certain named chemicals which have an industrial use, and for the solution of a number of specified problems in the bleaching, dyeing, and printing of textiles.

In the section of mechanical arts a prize of 500 francs with a silver medal is offered for a new method of construction of buildings suitable for cotton spinning, wool combing, or calico printing. The following subjects will receive medals:—a new type of steam boiler; an indicator of the total work done in a steam engine; new forms of

gas generators for gas engines; new types of gas engines; a new method of heating boilers; new methods of spinning, weaving, and dyeing textile fabrics; a simple cut-out for electrical installations.

The following subjects in natural history and agriculture will be awarded medals:—a geological or mineralogical description of part of Alsace; a detailed catalogue of plants in the neighbourhood of Mulhouse, Thann, Altkirch, and Guebwiller; a treatise on the fauna of Alsace; a treatise on the plants and insects inimical to agriculture in Alsace and the methods of destroying them.

In commerce and statistics the prize subjects are:—a study of methods of insurance against risks of transport; a treatise on insurance against fire, with especial reference to the factories of Alsace; a memoir on the variation in the price of coal in Alsace during the last thirty years; a study of the effect of taxation on industrial development.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The Vice-Chancellor has announced to the Senate the munificent gift of 1750*l*., made by Dr. Ludwig Mond towards the fund for increasing the stipends of the Stokes and Cayley university lecturers in mathematics.

The detailed proposals put for the diploma in forestry were to be discussed on Thursday last. Apparently they satisfied the members of the university, for there was no criticism made on them.

The degree of Master of Arts, *honoris causa*, is to be conferred upon Mr. R. I. Lynch, curator of the botanic garden. Mr. Lynch is well known as a writer on horticultural subjects.

On the nomination of the board of geographical studies, Dr. Guillemard and Sir G. D. T. Goldie, K.C.M.G., F.R.S., and on the nomination of the council of the Royal Geographical Society, Sir Clements R. Markham, K.C.B., F.R.S., and Dr. J. Scott Keltie, have been appointed members of the board of geographical studies for the year beginning January 1, 1906.

Mr. J. B. Peace has been appointed chairman of the examiners for the mechanical sciences tripos, 1906.

The general board of studies has approved Mr. H. J. H. Fenton, of Christ's College, for the degree of Doctor in Science.

The following notice of the next award of the Walsingham medal has been issued:—The medal is to be awarded for a monograph or essay giving evidence of original research on any botanical, geological, or zoological subject. The competition is open to graduates of the university who at the time fixed for sending in the essays are under the standing of Master of Arts. The essays for the ensuing year are to be sent to the chairman of the special board for biology and geology (Prof. Langley, The Museums) not later than October 10, 1906.

The special board for biology and geology give notice that the Gedge prize will be offered for competition in the Michaelmas term, 1906. The prize will be awarded for the best original observations in physiology, but a candidate who has received a certificate of research from the university will not be entitled to submit an essay which is substantially the same as the dissertation for which such certificate of research was granted. Candidates need not necessarily be graduates of the university. Essays are to be sent to the professor of physiology not later than October 1, 1906.

DR. A. J. EWART, special lecturer in vegetable physiology, Birmingham University, has been appointed professor of botany in the University of Melbourne in succession to the late Baron von Müller.

THE will of the late Mr. John Edward Taylor, part proprietor and a former editor of the *Manchester Guardian*, on which probate was granted in London on December 9, among numerous bequests, leaves, on the decease of the widow, 20,000*l*. to the Victoria University of Manchester.

AT a meeting of the council of the University of Birmingham held on December 6, the Chancellor announced that the family of the late Mr. Harding had offered 10,000*l*. to the Birmingham University for the erection of a library. The offer has been gratefully accepted by the council.

ON Tuesday, December 5, Sir W. Martin Conway distributed the prizes and certificates gained by the students at the Sir John Cass Technical Institute during the past session. Sir Owen Roberts, chairman of the governing body, presided. Mr. George Baker stated that the scope of the work of the institute and the number of students continued to progress steadily, and that a large proportion were studying subjects bearing directly upon the industries in which they were engaged. Sir Martin Conway, in the course of his address, pointed out that people in this country suffer from a confusion of ideas in respect to education, and that they do not believe sufficiently in the necessity of giving the highest possible education to the directing brains of industries, nor do they understand sufficiently the length of time and the experience that are required for skilful hands to receive their full equipment. He remarked that the real struggle with Germany in manufactures is due to the enormous number of highly educated men turned out at the German universities; it is not a question of technical education, but of scientific education. The German is not a whit more scientific or better than the Briton, but faith in science which exists in Germany is lacking in England, and this gives the Teutonic tortoise the advantage over the British hare.

THE following bequests and gifts for higher education in the United States are announced in *Science*. By the will of the late Mr. Stephen Salisbury, the Worcester Polytechnic Institute receives a bequest of 40,000*l*. This money comes without restrictions of any kind on the part of the testator. In addition to this bequest, Mr. Salisbury, at the time of his resignation a few weeks ago from the presidency of the board of trustees, made an additional gift to the institute of 20,000*l*., to be paid immediately. Formal announcement of the 50,000*l*. legacy to the Sheffield Scientific School from the estate of the late Mr. M. D. Viets has been made by Prof. Russell H. Chittenden, director of the school. The bequest will be used for the physical, mathematical, and general scientific needs of the school. The late Mr. Frank Harvey Cilley, the engineer, has bequeathed the residue of his estate, which will probably amount to 14,000*l*., to the Massachusetts Institute of Technology. Mr. T. P. Shonts, chairman of the Isthmian Canal Commission, has given to Monmouth College 2000*l*. as part of the 6000*l*. needed to obtain an additional 6000*l*. which Mr. Andrew Carnegie had promised to give the college for a library. The late Mr. Stephen Salisbury, of Worcester, Mass., has bequeathed 40,000*l*. to the Worcester Polytechnic Institute, 50,000*l*. to the American Antiquarian Society, and 1000*l*. and a site for a building for the Worcester Natural History Society.

PROF. W. J. ASHLEY, dean of the faculty of commerce in the University of Birmingham, distributed on December 6 the prizes gained by candidates at the examinations of the London Chamber of Commerce. During the course of a subsequent address, Prof. Ashley remarked that the science of commerce has yet to be made, but, in his opinion, a true science of commerce is capable of being created. At present, however, it does not exist. Its formulation should have been the task of the political economists; but hitherto English economists have been too content to pursue the results, the conclusions to be reached by a process of reasoning starting with certain assumptions. It is necessary that the problems which actually present themselves to a business man in the course of his operations should be realised and studied, and that the various ways in which they have been approached and faced ought to be brought together, grouped, criticised, and analysed. The function of the economist is not to arrive at general abstract conclusions and then look round in the world of business for examples or illustrations of the conclusions arrived at. He should condescend to a more concrete and a more patient survey of the actual facts of real life. Prof. Ashley considers it to be vitally important that the highest type of education shall be brought into close touch with the realities of economic life. If that is properly done it will not degrade education, but vivify it.

THE current number of the *Monthly Review* contains an article on public school education by Mr. A. C. Benson, in which some valuable testimony as to the inadequacy as a training for life of a purely classical education is given. The question as to what are the intellectual accomplishments of a boy of average intelligence who has been through a public school and a university is answered in the following words:—"He knows a very little Latin and Greek, and he endeavours to put them out of his mind as fast as he can; he knows a little science; perhaps a little history, mostly ancient. He cannot generally calculate correctly in arithmetic; he knows no modern languages to speak of; he cannot express himself in simple English, and his handwriting is often useless for commercial purposes." And later, we read, "he has learnt to think the processes of the mind dreary and unprofitable, to despise knowledge, to think intellectual things priggish and tiresome." Mr. Benson summarises his contentions in the following words:—"believing intensely, as I do, in the possibilities of intellectual education, I have tried to judge the classical system as fairly as I can by results, and I see that those results are in many cases so unsatisfactory and so negative that experiments are urgently needed. Simplification seems to me to be the one essential thing." If a writer who was formerly a master at our greatest public school finds it necessary to write in this plain manner, it is evidently high time that scientific methods were applied to obtain an answer to the question, what constitutes a suitable public school education, and how can it be secured?

A LARGE audience assembled at the Borough Polytechnic Institute on Monday evening, December 4, on the occasion of the thirteenth annual meeting and distribution of prizes and certificates. The chairman, Mr. Leonard Spicer, said the work of the institute was going forward with great strides, and he feared that, even allowing for the additions to the building which had recently been made, the governors would again be faced with the problem of knowing how to house the students. Although the word "polytechnic" is still associated in many minds with recreation and amusements, the chief work of institutes of this kind lies in an educational and technical direction, 15,000*l.* a year being the least sum upon which the work at the Borough can be carried on at present. Mr. C. T. Millis, the principal, read the annual report, which disclosed a very satisfactory state of progress of the institute. An experiment is being made in the direction of coordination with London County Council evening schools, and several new classes have been started. A satisfactory feature of the work of the institute is the readiness with which intending students ask for and follow advice given as to their courses of study, and the increasing number of students who attend for two, three, and four years. After the certificates, which numbered considerably more than five hundred, and the numerous prizes were distributed by Lady Lockyer, Sir Norman Lockyer, K.C.B., delivered an address. In a few remarks, Prof. Perry claimed for the polytechnic institutions of London that they were doing a work that was unprecedented, and which our colonies are now endeavouring to imitate. He had recently returned from South Africa, where he found the people following the lead which London was now giving in the matter of technical education. Votes of thanks were proposed and seconded by Sir Philip Magnus and Mr. W. F. Sheppard.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 16.—"The Electrical Conductivity of Dilute Solutions of Sulphuric Acid." By W. C. D. **Whetham**, F.R.S.

The equivalent conductivity of neutral salts when dissolved in water approaches a limiting value as the dilution is increased; with solutions of acids and alkalies, however, the equivalent conductivity reaches a maximum, and then falls rapidly as the dilution is pushed farther.

It has been supposed that this diminution of equivalent conductivity at extreme dilutions is due to interaction between the solute and the impurities which remain even in re-distilled water.

Kohlrausch has given evidence to show that the chief impurity in water carefully re-distilled is carbonic acid, and Goodwin and Haskell conclude that the diminution of equivalent conductivity of dilute acids is due to the presence of carbon dioxide.

In order to examine the real effect of carbonic acid and other impurities on the conductivity of an acid solution, the writer and his wife have carried out an investigation in which the amount of impurity was varied, and the result observed. The conductivity of dilute solutions of sulphuric acid and its variation with concentration was determined in four solvents:—(1) good quality re-distilled water; (2) the same water to which a trace of carbon dioxide had been added; (3) the same water with a trace of potassium chloride; (4) the same water which had been freed as far as possible from carbonic acid and other volatile impurities by repeated boiling under diminished pressure.

In each case the conductivity of the solvent was subtracted from that of the solution. The results may be summarised as follows:—

Within the limits of experimental error, the equivalent conductivity of a dilute acid is not affected by boiling the water under diminished pressure, though the conductivity of the solvent is thereby much diminished. The equivalent conductivity of the acid is also unaffected by the addition of a small quantity of potassium chloride to the water, though the conductivity of the solvent is thereby much increased. But, by the addition of a little carbonic acid, the equivalent conductivity of the sulphuric acid is diminished appreciably. It is natural to conclude that, while the presence of carbonic acid would produce a diminution of equivalent conductivity of the same character as that observed, it does not explain the total effect.

"The Accurate Measurement of Ionic Velocities." By Dr. R. B. **Denison** and Dr. B. D. **Steele**. Communicated by Sir William Ramsay, K.C.B., F.R.S.

The authors have succeeded in devising an apparatus with which it is possible to compare and measure the velocities of the ions of a given salt without using gelatin or other membrane during the actual experiment. This enables the method of direct measurement of ionic velocities to be extended to dilute solutions, and the results obtained are free from any error due to electric endosmose.

The transport number and the average absolute velocity of the ions of a number of salts have been measured at dilutions down to one-fiftieth normal, and at two temperatures, 18° C. and 25° C. It is easy to measure by this method the transport number of the ions of some salts which present great difficulty by the analytical method of Hittorf, *e.g.* $KClO_3$, $KClO_4$, $KBrO_3$. The following are some of the numbers obtained for the anion transport number:—$KCl\ n/10$, 0·508; $NaCl\ n/10$, 0·618; $KCl\ n/50$, 0·507; $CaCl_2\ n/50$, 0·587. The corresponding numbers determined by the analytical method are 0·508, 0·617, 0·507, 0·59.

The values obtained by the authors for the average velocity of the ions in cm./sec. agree in a remarkable manner with those calculated by Kohlrausch from conductivity data, and form a striking confirmation of the ionic theory of solutions. The values of the ionic velocity of the potassium ion in KCl, KBr, and KI are, for example, found to be:—at $n/10$, 0·000563, 0·000562, 0·000564 cm./sec.; at $n/50$, 0·000606, 0·000598, 0·000599 cm./sec. at 18° C.

It is claimed that the method is at least as accurate as that of Hittorf, and an experiment can be performed in about one-tenth of the time. It also gives a means of comparing the degree of dissociation of salts containing a common ion.

Mineralogical Society, November 14.—Prof. H. A. Miers, F.R.S., president, in the chair.—The determination of the angle between the optic axes of a crystal in parallel polarised light: Dr. J. W. **Evans**. The crystal plate is rotated on the optic normal as axis, and the positions are determined in which the relative retardation is nil. This may be observed by using a gypsum plate or the double quartz wedge devised by the author. In the latter case the positions in question are marked by the coincidence of the bands in the two halves of the wedge. This gives a very exact reading if strictly parallel light be employed.—Mineralogical notes (diopside and albite): Prof. W. J. **Lewis**. A large tabular crystal of white diopside, a brown

diopside of unusual habit, and a Carlsbad twin of albite were described.—Note on the crystallisation of drops, especially of potash-alum: J. **Chevalier.** The president described observations made by Mr. Chevalier on the crystallisation of drops of solution of potash-alum. These generally yield in succession (*a*) birefringent spherulites; (*b*) octahedra; and (*c*) a fine rectangular network. (*a*) is probably a less hydrated alum, and it becomes isotropic on exposure to moist air by conversion into (*b*). (*c*) is ordinary alum which is in a state of strain, owing to its rapid crystallisation, and becomes white and opaque after a time owing to the development of cracks. Drops observed upon a slide under the microscope behave differently according as they are in the metastable or labile condition. A metastable drop inoculated with (*a*), (*b*), or (*c*) deposits octahedra. A labile drop inoculated with (*a*) deposits spherulites, but inoculated with (*b*) or (*c*) deposits the rectangular network. When a metastable drop containing either octahedra or spherulites, or both, passes into the labile condition (by cooling or by evaporation), they may continue to grow unchanged. If, however, a fragment or germ of octahedral alum be introduced into a labile drop the network (*c*) is immediately produced. An alum crystal growing in a labile solution is surrounded by a zone of metastable liquid which prevents it from starting the network (*c*) characteristic of a labile drop. Experiments were made upon the action of various mineral substances in inducing crystallisation in metastable and labile drops. Among these the holosymmetric cubic crystals, and especially galena, exercise a remarkable effect in producing the network (*c*) in labile drops.—Note on the formation of gypsum crystals in a disused well at chemical works: C. J. **Woodward.** Groups of gypsum crystals were exhibited which were found thirty years ago studding the walls of an old well at Messrs. Chance's chemical works at Oldbury.—Notes on minerals recently found in the Binnenthal: R. H. **Solly.** The minerals described were (1) Ilmenite, in brilliant crystals, displaying marked hemihedrism and showing five new forms. It is associated with quartz, adularia, magnetite and mica, on mica schist. (2) Seligmannite; an exceptionally large and well developed crystal in dolomite. Unlike any previously described, it is untwinned; altogether forty-five forms were observed, of which twenty-one are new. (3) Marrite; two more crystals of this rare mineral were found, one tabular and the other sharply pointed in habit. (4) Proustite; a minute crystal deposited on a crystal of rathite. (5) Trechmannite; a crystal of this rare mineral displaying asymmetric hemihedrism, deposited on a crystal of binnite. (6) Hyalophane; in crystals of an unusual green colour.

Entomological Society, November 15.—Mr. F. Merrifield, president, in the chair.—*Exhibitions.*—A flower-frequenting beetle from the Transvaal, illustrating a remarkable device for the cross-fertilisation of flowers, one of the front feet being tightly clasped by the curiously formed pollinia of an Asclepias: Mr. **Arrow.**—A remarkable specimen of *Agrotis tritici*, taken this year at Oxshott, bearing a close resemblance to *A. agathina*, with which it was flying over heather: W. J. **Kaye.** The specimen was a good example of syncryptic resemblance brought about by the common habit of resting on heather.—A specimen of *Forficula auricularia* taken by Mr. R. A. R. Priske at Deal in September, 1905, having the left cercus normal, while the right was that of var. *forcipata*: W. J. **Lucas.**—Forms of South African Pierine butterflies taken during the dry season of the present year, together with specimens of the same species for comparison taken in the same localities: Dr. F. A. **Dixey.** He said that his exhibit illustrated the fact, now widely recognised, that these forms varied in general correspondence with the meteorological conditions prevailing at the different seasons.—A long series of *Hemerophila abruptaria* bred by the exhibitor illustrating the proportion of light and melanic forms derived from a light male and a light female: E. **Harris.**—A ♂ specimen of *Tortrix pronubana*, Hüb., taken by Mr. Harold Cooper at Eastbourne, either at the end of September or the beginning of October last: S. **Image.** The insect is new to the British list.—*Paper.*—Hymenoptera-Aculeata, collected in Algeria, part iii., Diploptera, by E. Saunders, F.R.S.: Commander J. J. **Walker.**

Linnean Society, November 16.—Mr. C. B. Clarke, F.R.S., vice-president, in the chair.—*Exhibitions.*—Specimens of British water Ranunculi, showing the modifications in the form of the leaves: H. and J. **Groves.** The authors pointed out that the species might be roughly grouped under three headings:—(1) those in which only broadly lobed aërial leaves were produced; (2) those in which submersed multifid leaves with capillary segments were also produced; and (3) those with multifid leaves only.—Photograph showing, of the natural size, the otoliths from thirty-five species of fishes, a collection made by the late Dr. David Robertson: Rev. T. R. R. **Stebbing.**—Leaf and seed of *Macrozamia spiralis* from Queensland, where the plant is stated to cause symptoms of paralysis of the hind-quarters of cattle eating the leaves: E. M. **Holmes.** The chemical nature of the constituents of the plant appears to be unknown.—*Papers.*—Contributions to the embryology of the Amentiferæ, part ii., *Carpinus Betulus*: Dr. Margaret **Benson,** Miss E. **Sanday,** and Miss E. **Berridge.** Material was collected early in July, 1902, and 1904, and more than 600 series of sections were obtained through ovules containing the earlier stages in the development of the embryo-sacs, until the first segmentation of the definitive nucleus had occurred. Former observations (see part i. in *Trans. Linn. Soc.*, ser. ii., bot. iii. (1894), pp. 409–424) were confirmed, and the following new facts obtained. The polar nuclei meet at the neck of the cæcum, descend together, and generally fuse near its base. The pollen-tube enters the sac in their vicinity, and emits one gamete into the cæcum, usually by means of a short spur. The gamete then makes its way to the definitive nucleus. The other gamete is carried up by the tube to the egg, with which it fuses. The egg then becomes clothed with a wall, and segmentation commences.—The membranous labyrinth of five sharks: Prof. C. **Stewart,** F.R.S.

PARIS.

Academy of Sciences, December 4.—M. Troost in the chair.—Contribution to the study of the distribution of the tsetse fly in French West Africa: A. **Laveran.** Since writing the earlier notes on the same subject, the author has accumulated additional material, details of which are now given.—On the deformation of quadrics: C. **Guichard.**—On Bode's law and the inclinations of the planetary equators to the ecliptic: E. **Belot.**—On the intrinsic brightness of the solar corona during the eclipse of August 30, 1905: Charles **Fabry.** The instrument used was a modified Mascart photometer. The intrinsic brightness found was, at a distance of 5′ from the edge of the sun, and in the direction of the equator, about 720 candles per square metre, or about 0·28 the intrinsic brightness of the lunar surface.—The inertia of the electrons: Marcel **Brillouin.**—On certain experiments relating to the ionisation of the atmosphere, executed in Algeria on the occasion of the total eclipse of August 30, 1905: Charles **Nordmann.** A continuous record of the positive ions present in the air was obtained, the instrument destined to measure the amount of negative ions being broken in transit. The curve given by the ionograph showed a marked minimum during the eclipse, thus agreeing with the views of Lenard, Elster and Geitel, who regard the solar radiation as one of the direct or indirect factors in atmospheric ionisation.—On the equilibrium diagram of the iron-carbon alloys: Georges **Charpy.** The influence of the rate of cooling on the composition of the casting has been neglected by the earlier workers on this subject. Details are given of a study of an alloy containing 2·90 per cent. of carbon, for which the Bakhuis-Roozeboom diagram is drawn.—The action of silicon on pure aluminium; its action on impure aluminium; silico-aluminides: Em. **Vigouroux.** Silicon does not form a definite compound with pure aluminium, but in presence of a third metal silicides of aluminium and this metal are formed, well defined crystallised substances, silico-aluminides.—On α-decahydronaphthol and the octahydride of naphthaline: Henri **Leroux.** α-Naphthol, treated with hydrogen by the method of Sabatier and Senderens, gives the decahydride, the details of the preparation and properties of which are given in the present note. Treated with a dehydrating agent it loses a molecule of water and gives an octahydride of naphthalene.—On victorium and the

ultra-violet phosphorescence of gadolinium: G. **Urbain.** The phosphorescence spectrum is given by one element when small quantities of a second element, called the excitor, are present. Either of these, in the pure state, gives no phosphorescent spectrum. These considerations have been applied to the examination of gadolinium, and the author regards the spectrum attributed to a new element, victorium, by Sir W. Crookes as due to a complex containing gadolinium.—On the existence of caoutchouc in a genus of Menispermaceæ: Jacques **Maheu.**—On prulaurasine, a crystallised cyanhydric glucoside extracted from the leaves of the cherry laurel: H. **Hérissey.** The method of obtaining this glucoside in a pure crystallised state from the leaves is given. Its formula appears to be $C_{14}H_{17}NO_6$, and under the action of emulsin it is hydrolysed to hydrocyanic acid, glucose, and benzoic aldehyde. It is an isomer of the amygdonitrile-glucoside of Fischer and the sambunigrin of Bourquelot and Danjou.—On the retrocerebral organ of certain rotifers: P. Marais **de Beauchamp.**—On phototropism of the larvæ of the lobster: G. **Bohn.**—On the geological structure of the eastern Pyrenees: Pierre **Termier.**—On the orientation which an elongated body will take when turning in a current of fluid: E. **Noël.**—On the Devonian fossils of the eastern Ahenet collected by M. Noël Villatte: Émile **Haug.** The collection of fossils made in the course of the Laperrine expedition is sufficient to prove the presence of the three principal subdivisions of the Devonian system, but the stratigraphical relations between the different terms cannot be exactly made out.—The influence of the summer rains on the yield of springs in the plains: M. **Houllier.**—The magnetic effects of lightning on volcanic rocks: Gaetano **Platania** and Giovanni **Platania.**

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 14.

ROYAL SOCIETY, at 4.30.—An Investigation into the Structure of the Lumbo-sacral-coccygeal Cord of the Macaque Monkey (*Macacus sinicus*): Miss M. P. Fitzgerald.—On the Distribution of Chlorides in Nerve Cells and Fibres: Prof. A. B. Macallum and Miss M. L. Menten.—The Mammalian Cerebral Cortex, with Special Reference to its Comparative Histology. I. Order Insectivora: Dr. G. A. Watson.—Observations on the Development of Ornithorhynchus: Prof. J. T. Wilson and Dr. J. P. Hill.—Further Work on the Development of the Hepatomonas of Kala-Azar and Cachexial Fever from Leishman-Donovan Bodies: Dr. L. Rogers.—The Action of Anæsthetics on Living Tissues. Part I. The Action on Isolated Nerve: Dr. N. H. Alcock.—Report on the Psychology and Sociology of the Todas and other Indian Tribes: Dr. W. H. R. Rivers.—On the Sexuality and Development of the Ascocarp of *Humaria Granulata*, Quel.: V. H. Blackman and Miss H. C. I. Fraser.—On the Microsporangia of the Pteridospermeæ with Remarks on their Relationship to Existing Groups: R. Kidston, F.R.S.—The Araucarieæ, Recent and Extinct: A. C. Seward, F.R.S., and Miss S. O. Ford.—On the Spectrum of the Spontaneous Luminous Radiation of Radium. Part IV. Extension of the Glow: Sir William Huggins, K.C.B., O.M., F.R.S., and Lady Huggins.

MATHEMATICAL SOCIETY, at 5.30.—On Well-ordered Aggregates: Prof. A. C. Dixon.—Tables of Coefficients for Lagrange's Interpolation Formula: Col. R. L. Hippisley.—On the Representation of certain Asymptotic Series as Convergent Continued Fractions: Prof. L. J. Rogers.—On a New Cubic Connected with the Triangle: H. L. Trachtenberg.—Some Difficulties in the Theory of Transfinite Numbers and Order Types: Hon. B. A. W. Russell.—The Imaginary in Geometry: J. L. S. Hatton.

THE JAR AND THE GENIE.

The Theory of Experimental Electricity. By W. C. D. Whetham. Pp. xi+334. (Cambridge: The University Press, 1905.) Price 8*s.* net.

Electric Railways: Theoretically and Practically Treated. By S. W. Ashe and J. D. Keiley. Pp. 285. (New York: D. Van Nostrand Co.; London: Archibald Constable and Co., Ltd., 1905.) Price 10*s.* 6*d.* net.

Modern Electric Practice. Vol. vi. Edited by M. Maclean. Pp. vi+318. (London: The Gresham Publishing Co., 1905.) Price 9*s.* net.

THERE is a tale in the "Arabian Nights" of a fisherman who, after a day's ill luck, cast his net for the fourth and last time with a prayer to Allah that he might have a good haul. He drew to shore a copper jar of curious construction and mysteriously sealed, which on being opened was found to have confined a genie possessed of remarkable powers. As the genie proposed to reward his liberator by taking his life, the fisherman induced him to return into the jar, in which he again confined him. About two centuries ago the body of fishermen who called themselves then natural philosophers drew to shore from the sea of natural phenomena a similarly remarkable jar capable also of confining a very powerful genie. The discovery of the Leyden jar, we are told, "caused the greatest excitement in Europe and America," two continents which three years ago exchanged congratulatory messages across 2000 miles of ocean by means of Leyden-jar sparks. This, the most recent sensational demonstration of the powers of the genie, is by no means the most important; he has truly produced as great a revolution in the doings of mankind as any of his imaginary predecessors.

Ever since the genie has been released the fishermen have been divided into two camps; those who were most interested in studying the jar with the view of discovering the wonderful properties by which it could confine so powerful an agent, and those who have preferred to take such things for granted and have devoted themselves to putting these powers to the service of mankind. As time has advanced the work of each camp has become more and more differentiated, the "theorists" pressing always deeper and deeper into the region of first causes, but ever and again bringing to the surface some fresh discovery on which the "practical men" are quick to seize and which they soon adapt to useful purposes. Thus each continues to supplement the work of the other until it is hard to tell to which is owed the greater debt of gratitude—to those but for whom the powers of the genie would have remained concealed, or to those but for whom they would have remained discovered but unused.

Mr. Whetham's book is an admirable exposition of all that the theorists have discovered so far. "To some extent," he writes in the preface, "even a scientific text-book must be a piece of literature and a work of art." "Experimental Electricity" can certainly claim to be both. The present writer does not profess to be very old, but the development of electrical theory has been so rapid since he first studied its elements that the text-books from which he learnt are more out of date than is Euclid as a text-book of modern geometry. An elementary text-book should give a comprehensive survey of the whole of its subject in such a way as to stimulate the curiosity and imagination of the student and this the book before us does. It is written in a clear and simple style, and the mathematics necessary are such as any student beginning his university career should have at hand. A very prominent and valuable feature of the book is the frequent reference to and quotation from the works of the founders of modern electrical theory, notably Faraday and Maxwell. The story which it tells of the development of this theory from the first suggestions of Faraday to the most recent conceptions of J. J. Thomson, Larmor, and others is one of extraordinary fascination and interest, and we cannot conceive any earnest student laying down the book without a desire to help to the best of his ability in solving the riddle with which it closes.

Books such as Mr. Whetham's should be read not only by the student who wishes to enrol himself in the scientific camp, but also by those who intend to become engineers. The engineer can never be the worse for a sound knowledge of what the men of science are doing. Incidentally he may be prevented from making some of the mistakes which Messrs. Ashe and Keiley make in the first chapter of their otherwise excellent book on electric railways. For example, these writers in the course of a few lines speak of the watt, first as power, then as work, and finally as energy. But after a few pages of this "miscallin' technicalities" they proceed to the more serious business of their book, and here there is little to which objection can be raised. The book is a good example of some of the feats that the genie has accomplished. It is a good example, too, of the extreme specialisation so characteristic now of all branches of electrical engineering. The title is somewhat broad, as the subject-matter is practically confined to rolling stock and rolling-stock equipment. The illustrations are plentiful and very clear.

If those who would learn what the jar is made of should study Mr. Whetham's book, those who would know in a general way the genie's powers should read "Modern Electric Practice," of which the present volume is the sixth and last. We have already reviewed the previous volumes and have pointed out what we consider to be somewhat serious defects in the plan and general arrangement of the work. Still, as a general summary of all the modern applications of electricity these volumes are not to be despised, especially when their very numerous illustrations are remembered. We would like to suggest that in future editions these are published without the text. The present volume contains very good articles on telegraphy and telephony; the article on electromedical appliances is disappointing in the extreme. There is in addition a good index to the whole six volumes.

The three books the titles of which head this review are typical of the three classes of men who have made the electrical industry. Mr. Whetham's of the seekers after truth who are always asking for more light and have discovered all the fundamental principles on which the industry is based, Messrs. Ashe and Keiley's of the pioneers who have developed the practical possibilities of these principles, and "Modern Electric Practice" of the great majority who are content to follow where others lead but whose united efforts have placed at the disposal of all mankind the forces latent in the philosopher's jar. MAURICE SOLOMON.

HYGIENE AT SCHOOL.

Text-book of Hygiene based on Physiology for the use of School Teachers. By A. Watt Smyth. Pp. xvi+256. (London: Simpkin, Marshall and Co., Ltd.) Price 6*s*.

MRS. WATT SMYTH rightly says in her preface that

"Physiology is the science of the action of the body in health, hygiene the practical application of this science; it is obviously impossible to understand the laws of hygiene without a knowledge of the fundamental principles of physiology."

She has set herself the task of providing a text-book of hygiene founded upon physiology, for the use of teachers, in order that they may comprehend the hygienic needs of the pupils committed to their charge. Hitherto the books written with this object (and there are several) have either been good as text-books of elementary physiology and bad as text-books of elementary hygiene, or *vice versâ*; and Mrs. Watt Smyth is to be congratulated upon having brought these two subjects, which are so intimately associated with each other, into a fairly satisfactory relationship, and upon having dealt with each in a very commendable manner. It must be said, however, that the physiological matter of the book is the better, and that in many instances the hygienic matter could have been presented in greater fulness of detail with advantage. The space given to physiology far exceeds that devoted to hygiene, and while the demands of the former subject upon space are necessarily somewhat greater, there can be no two opinions that the physiology in many respects is too elaborate for the purpose to which this book is dedicated. Some non-essential matter is included; for instance, a description is given of the ethmoid bone, the number of bones it articulates with, and the time when ossification is complete; the number of separate centres of ossification is also given of other cranial bones; the minute structure of the salivary glands is entered into with unnecessary fulness, for the teacher is informed that

"the secreting cells of the salivary glands are of two main types, according as the secretion of the gland is mainly serous or albuminous (Parotid), mainly mucous (sub-lingual) or both (sub-maxillary). In a gland that has not been recently secreting, the mucous secreting cells, which are round or oval, are distended with a clear substance, mucigen, from which mucus is formed when the gland becomes active. The cells of the glands which yield an albuminous secretion are cubical and almost fill up the acini. Their protoplasm is full of dark granules before secretion occurs; when it begins, the granules diminish in number and finally almost completely disappear."

These instances are referred to as illustrations of a certain lack of appreciation, which is evident here and there, of what is essential and what is not; for it is impossible to see what practical application can be claimed of the knowledge of the above facts. The illustrations and diagrams, moreover, are anatomical and histological. There is no single illustration of any form of sanitary apparatus or appliance, and these matters are referred to in the text often in such a cursory manner that the reader would find it impossible to form a satisfactory conception of their true nature.

Mrs. Watt Smyth deals with each subject on an excellent plan. First she gives a brief account of the physiology of the subject discussed (with special reference to any notable feature of these physiological processes in childhood), and then she proceeds to deal with the hygienic principles and practices which rest upon these foundations. Her scheme is well illustrated in the chapter on respiration and air; the nose, larynx, trachea, and lungs are first described, then the mechanism of respiration is explained, next the constitution of the air prior and subsequent to respiration is set out, and then there follows the consideration of the problems of ventilation and heating, and the evil consequences which result when these provisions are insufficient or faulty.

The other chapters of the book fairly cover the necessary ground, and the chapters upon the special senses and the muscular system (the latter including a syllabus of physical exercises based on the Swedish system) are very complete.

In conclusion, reference should be made to the great care which has been exercised in the preparation of this work. The facts set out are entirely accurate and the opinions expressed are sound, without exception. The author acknowledges her indebtedness for information and counsel from such authorities as Dr. Dawson Williams, Dr. James Kerr, and Miss Turner.

REGENERATION IN ROOTS.

Studien über die Regeneration. By Prof. B. Němec. Pp. 387; with 180 figures in the text. (Berlin: Gebr. Borntraeger, 1905.) Price 9.50 marks.

IN this somewhat bulky volume the author describes and discusses at some length the result of his numerous experiments on the regenerative processes that occur in wounded roots.

It is well known that if the tip be removed from a growing root a new apex is commonly differentiated, growth in length commencing once more when the new tip has become completely formed. The objects of Dr. Němec's investigation have been to endeavour to throw some light on the nature of the process of regeneration itself, the causes that initiate and determine its occurrence, and the meaning of the physiological events that are associated with it. The

methods adopted were extremely simple. The tips of growing roots, chiefly of seedlings, were injured in various ways by making incisions into the region about the apex, and the reactions that ensued were carefully followed and compared.

It was found, in confirmation and extension of the less complete observations of Prantl and of Simon, that the roots of ferns never truly regenerate themselves as do those of flowering plants. Possibly the difference is to be attributed to the more definite concentration of formative protoplasm in the apical cell of the former, as contrasted with its greater extension as layers in the roots of the latter. At any rate, no regeneration occurs in the roots of ferns, although some attempts at healing the actual wound may be made.

The case is different with the roots of phanerogams, although in them also the conditions of regeneration are more limited than might have been anticipated. In the first place, no union of the halves of longitudinally cut roots took place; the damaged apex was either replaced by a new one on either side of the slit or else the regeneration was confined to one half.

An annular incision made just behind the tip of the root into the cortex and extending as the endodermis fails to give the stimulus requisite to produce a fresh apex. Healing of the wound is more or less in evidence, but the original apex continues to function, and to supply cells for the further growth and elongation of the root. But if the knife has passed through the next layer, the pericycle, regenerative phenomena at once set in. A new apex, with all the complicated layers, is formed just behind (*i.e.* proximally to) the wound, and it is especially interesting to discover that the statolith starch now disappears from the original tip, to be transferred to, or at any rate to reappear in, the new one.

Lateral incisions are ineffective to bring about the differentiation of a new apex unless the slit has severed at least half the circumference of the pericycle. If this be done regeneration takes place, with the concomitant appearance of statolith starch in the new organ. All the experiments made on the roots go to emphasise the great importance of the pericycle in connection with regenerative processes, although it is not from this layer itself that the new tip is differentiated, but from the indifferent plerome cells within it. The damage done to the pericycle appears to act as an interruption of the coordinative relations between the various parts of the embryonic region as a whole. When this coordination is thus interrupted the capacity of giving rise to entire organs that is resident in the embryonic protoplasm asserts itself, and the new formation thus appears. We know as a matter of fact that the pericycle retains the embryonic condition until relatively late, since from it arise the normally produced lateral roots. Of course, the processes underlying the regenerative processes are by no means cleared up by the experiments indicated above, but at any rate certain definite facts have been ascertained, and further lines of profitable investigation readily suggest themselves.

Comparatively few anomalous cellular effects were observed. In the exceptional case of one fern root, however, the nuclei of the healing (not regenerative) cells exhibited irregularities both in their modes of division and in the number of their chromosomes which were commonly excessive. Multinucleate cells were also observed in the plerome of a wounded root of Ricinus, but they apparently took no part in the actual regenerative processes.

The book as a whole forms an important contribution to the literature of regeneration, its chief merit perhaps lying in the numerous problems it suggests for future investigation. It contains a bibliography that should be useful, but it would have been materially improved by the addition of a good index.

OUR BOOK SHELF.

Heredity. By C. W. Saleeby, M.D. Pp. 118. (London and Edinburgh: T. C. and E. C. Jack, n.d.) Price 1*s.* net.

The appearance of a little shilling book on heredity is almost startling, when we consider the difficulty of the subject and the relative youth of its exact study. That a book like this should be possible indicates that considerable progress has been made in recent years. Was it not Leibnitz who said, "The more a science advances, the more it becomes concentrated in little books"? But it indicates also a noteworthy skill on the author's part. Without attempting to slur over difficult themes, *e.g.* Mendelism, as if they were easy, he has given us a clear and interesting exposition, which will be widely appreciated. It is a wonderful *multum in parvo*, dealing lucidly, for instance, with the contrast between hereditary resemblance and variation, between the germ-plasm and the body, between germinal variations and somatic modifications, between inherited nature and the results of nurture, between inborn and congenital characters, and so on. Even to have made these distinctions clear, so that they may be understanded of the people, is an achievement. As was natural in a book of this kind, the author takes up an eclectic position, and quotes freely from various writers—from one about ten times. He is inclined to allow that there is a limited transmission of "acquirements" or modifications, but the only instance we have found is an inept one—that bacteria may transmit an exaltation of their virulence. He agrees with Dr. Archdall Reid on many points, *e.g.* that amphimixis never produces more than regressive variations, but does not think that this author satisfactorily accounts for the origin of spontaneous variations. He has the same complaint to make of Weismann, but in regard to a view which that progressive biologist no longer holds, as, indeed, the author seems to know (p. 54). We may also note that even in "The Germ-Plasm" Weismann did not teach that "parthenogenetic species cannot vary"; in fact, he made experiments showing reversion in parthenogenetic generations of Cypris. There is a useful chapter on "physical degeneration," but we do not understand the author when he says that those who believe in progressive degeneration "have it incumbent upon them to demonstrate either the falsity or the suspension of the law of natural selection." Surely the many "degenerate" animals that we know have not become what they are without the help of selection. Another point that we do not understand is how the fact that "one-half of the nuclear chromatin of each gamete is thrown aside prior to the fusion of the two nuclei," "obviously

corresponds exactly with Galton's assertion that the two parents between them contribute one-half of the total heritage of the offspring." There is surely a screw loose here. Dr. Saleeby's vivacious style will fascinate some readers and help them over difficult themes, but we wish that he had been sometimes less conversational, as when he speaks of the Bathmic theory of organic evolution as "an amusing piece of nonsense." J. A. T.

The Practical Photographer. Library Series. Nos. 24, 25, and 26. 24 and 25, Pictorial Printing, parts i. and ii. Pp. xx+64 and xx+64. 26, Artificial Light and Night Photography. Pp. xx+64. Edited by Rev. F. C. Lambert. (London: Hodder and Stoughton, 1905.) Price 1s. net.

WE have before us three more additions to this very practical and useful series of photographic handbooks, with which most of our photographic readers are now well acquainted. The first two are devoted to pictorial printing, in which are brought together many methods by which the negatives may be altered, the print controlled during printing, or generally or locally modified according to desire.

For the most part No. 24 treats chiefly of the employment of one negative only, while No. 25 is devoted chiefly to combination printing and enlarging, cloud negatives, and cloud printing. Both numbers are preceded by interesting and well illustrated *résumés* of the pictorial work of Bessie Stanford and Percy Lewis, which to the beginner should serve as admirable types of high order work.

The third number belongs to quite another branch of photography, namely, that in which the incident light on the object is for the most part artificial, such as flashlight, candle light, gas light, acetylene, &c. Here we have a collection of notes by numerous workers, all of whom have secured some interesting pictures by one or other of these methods. As before, the reader is not left to gather his ideas from the text alone, but is introduced to some interesting pictures with notes describing under what conditions they were taken. This number also contains an account by the editor of the pictorial work of J. C. Warburg, with a reproduction of many of his most typical photographs.

These three numbers thus form a welcome addition to those previously published, and will certainly be appreciated by those workers to whom they specially appeal.

Introduction to the Study of Organic Chemistry. By John Wade, D.Sc. (Lond.). New and enlarged edition. Pp. xx+646. (London: Swan Sonnenschein and Co., Ltd., 1905.) Price 8s. 6d. net.

THE fact that the present volume has reached its second edition points to the public appreciation of Dr. Wade's book. This is not surprising.

The arrangement of the subjects bears evidence of the author's thought, and the immense number of facts compiled speaks eloquently of his industry.

There are several novel features to which the author directs attention in the preface, and which possess certain merits. There is no doubt that charts or surveys, which serve to show, in a condensed form, the relation of a variety of compounds, are an aid to the memory, and the author has introduced them freely.

The principle of making a thorough study of a single common substance like ethyl alcohol and then dealing with its more important derivatives before thrusting the student into the tangle of homologous series has very much to recommend it.

Perhaps the title of the book is a little misleading. One would be inclined to suppose that a student who was familiar with these 624 pages of closely printed matter might be regarded as a well informed organic chemist; but he has only an introductory knowledge. We must express our respect for those who have passed beyond this "introduction," whilst others who may be examined in the information required by Dr. Wade's introductory standard demand our sympathy. The illustrations exhibit rather too plainly the defects of photography applied to glass apparatus, though they possess a realistic character which may appeal to the student. We are glad to notice the author's respect for the traditional spelling of the word *radical.* J. B. C.

The Romance of Insect Life. Interesting Descriptions of the Strange and Curious in the Insect World. By Edmund Selous. With twenty-one illustrations by Lancelot Speed and Carton Moore Park. Pp. 352. (London: Seeley and Co., Ltd., 1906.)

THE letterpress consists of a series of extracts, derived from a variety of sources, relating to ants, termites, locusts, butterflies, water-insects, fireflies, scorpions, &c., connected together by general observations on all kinds of subjects. Occasionally the compiler's remarks on the senses of insects or on mimicry are worthy of notice, but they are frequently in bad taste and often inaccurate, which is not surprising, as we are constantly told that he is only quoting his data second-hand, and has not seen the original records.

This is a pretty book, but otherwise we regret that we have little to say in its praise. The author suggests that the genus of grasshoppers called "Scudderia" were so named because they "scud," though Scudder's name is actually referred to on the opposite page. As an illustration of style and inaccuracy we may quote the following:—"From 1778 to 1780 a dreadful curse of locusts, alluded to by Southey in his 'Curse of Kehama,'—or perhaps forming the subject of that poem—I really don't know—fell upon the Empire of Morocco." There are *two lines* relating to locusts in the "Kehama," and it is "Thalaba" in which they are noticed at greater length.

There are really only sixteen page illustrations, some of them being double—*i.e.* divided in the middle, and thus making up the twenty-one of the title-page.

Most of our scientific men must be very far behind other people, for Mr. Selous tells us, "Everybody knows nowadays how all the different species of animals and plants, living and extinct, have come into existence," &c., &c.

Errors in Latin names abound, the worst being Orthoptera for Ornithoptera wherever it occurs. It is a pity that a book intended to popularise natural history should not have been more carefully written and edited. It almost looks as if the compiler thought anything would be good enough for his prospective readers.

The Art and Practice of Laundry Work for Students and Teachers. By Margaret Cuthbert Rankin. Pp. 191. (London: Blackie and Son, Ltd., 1905.) Price 2s. 6d.

THERE is little that is scientific in this book; it gives the impression, indeed, that even the teachers of laundry work are guided by empirical rules. It should be possible to inculcate the broad scientific principles upon which the art and practice are based while teaching girls how to do their laundry-work successfully. The washing of clothes, and the other processes through which they pass in the laundry, would then not be matters of rule of thumb, but intelligent applications of scientific principles to particular purposes.

LETTERS TO THE EDITOR.

Radio-activity of Ordinary Matter in connection with the Earth's Internal Heat.

MR. CAMPBELL's letter in your last issue (p. 152) reminds me of a point to which I have intended for some time to direct attention. Prof. Rutherford ("Radio-activity," second edition, p. 494) has calculated that the radio-activity required to compensate for the earth's internal heat is much exceeded by the (apparent) activity of ordinary materials, as determined by me (*Phil. Mag.*, June, 1903).

Thus the smallest activity I observed was about 10^{-4} times that of uranium nitrate, or 7×10^{-11} times that of radium: whereas the amount of activity, per unit mass of the earth, required to compensate for the loss of internal heat is only $4{\cdot}6\times10^{-14}$, or less than one-thousandth part of the activity computed to be actually there.

We cannot well assume a much smaller apparent radio-activity for the unknown material of the earth's interior, for all materials hitherto examined have given effects of the same order of magnitude, the radio-active elements, of course, excepted.

The simplest way out of the difficulty is to suppose that the apparent radio-activity of ordinary materials is not a volume effect of the same nature as that of radium, but that it is merely a superficial effect of quite a different kind, and only occurring at an exposed surface. It is difficult to understand why Prof. Rutherford did not draw some such conclusion. I do not know if he doubted the correctness of my results. It is easy, however, to confirm them from other sources. Thus C. T. R. Wilson (*Proc. Roy. Soc.*, vol. lxviii. p. 158) found the current through the air in a vessel of 163 c.c. capacity equal to $2{\cdot}0\times10^{-6}$ electrostatic units per second; this is equivalent to 7×10^{-17} electromagnetic units. Madame Curie ("Thesis," p. 14) found the current through a flat vessel of about the same size, the bottom being covered with uranium nitrate, equal to 7×10^{-13} (electromagnetic). If this vessel had been wholly lined with uranium, the current would have been more than doubled, say 2×10^{-12}. Thus the ratio of activities may be put at 3×10^{4}, as against 10^{4} in my own experiments. Considering the various activity of ordinary materials, and the rough nature of the comparison in both cases, this measure of agreement is fully confirmatory.

As the question of the earth's internal heat has been raised above, I may mention that I am engaged on an extensive investigation of the amount of radium contained in various rocks. The majority of those rocks which I have as yet tried (chiefly sedimentary) contain a good deal more radium than the percentage which would keep up the heat supply. Much more, however, must be done before any confident statement can be made as to the average amount of radium in the earth's crust.

Experiments are also in progress with native iron, both terrestrial and meteoric, with the idea that this may be representative of the composition of the earth's interior.

Sunnyside, Cambridge. R. J. STRUTT.

Magnetic Storms and Aurora.

IN his letter in your issue of December 14 (p. 152) Mr. F. C. Dennett assigns a positiveness and a generality that were not intended to the statement in my previous letter that on November 12 "no special auroral display seems to have been noted in this country." In years of sun-spot maximum, in the belt of greatest auroral frequency, nights wholly free from aurora are probably the exception. In the Shetlands, or even in the north of Ireland, aurora is a much more common phenomenon than in the south of England.

On November 15 I learn from several sources that the aurora was particularly brilliant, and the apparent movements especially lively during the time 8.53 to 9.25 p.m., when the large declination movement occurred. Various Arctic explorers have stated that it is only when the aurora displays this variable character that there is any clear connection between it and magnetic disturbances in those regions where both phenomena have their maxima. The aurora on November 12 is said by the Lisburn observer to have been of "the usual type" exhibiting "a steady glow." It would be interesting to know whether this aurora was observed at Lisburn or elsewhere *during the time of the large declination movement* (6.30 to 7.10 p.m. G.M.T.), and, if so, whether it then showed none of the brilliant and variable phenomena seen during the time of the large declination movement three days later.

For aurora to be observed on thirteen days in less than three weeks must, I think, be rather an unusual event for any place in England or Ireland; the Lisburn observer must keep a sharp look-out. CHARLES CHREE.

December 16.

The Total Solar Eclipse of August 30.

IN visiting Spain at the end of August of this year I was actuated by the desire once again, after an interval of twenty-three years, to witness the marvellous and unique phenomenon of a total solar eclipse. It is a sight which cannot be imagined—it must be seen. Happening at a time of maximum sun-spot frequency, it was reasonable to expect a considerable display of protuberances, and I wished to form my own idea of their size by checking their persistence or non-persistence through the phase of mid-totality on a day which otherwise may be taken to have been chosen at random. For this purpose a station on, or very close to, the line of central eclipse was essential. Torreblanca was chosen because it was the station of the Barcelona and Valencia railway which was nearest to the line of central eclipse, lying, in fact, about a mile to the south-west of it.

I observed the eclipse from the railway station, the position of which is lat. 40° 12′ N. and long. 0° 12′ E. (Greenwich). The railway and official time in Spain is that of Greenwich. By the clock at the railway station, mid-totality occurred between 1h. 18m. and 1h. 19m. p.m. Before the beginning of the eclipse I entered in my note-book half the expected duration of totality, 1m. 50s.; when I had observed the second contact, I wrote the time underneath, and, by addition, ascertained the time of mid-totality by my watch. The display of protuberances which appeared just before the moment of second contact, and on the part of the sun's limb which was about to be eclipsed, was, according to all witnesses, exceptionally brilliant. When the time of mid-totality came round I looked for these protuberances. They were absent. Not a trace of them or of any others was visible to the naked eye, and I searched the whole edge of the moon's disc with the greatest attention. Their absence was confirmed by Stephan (*Comptes rendus*, October 9), observing with the best instrumental aid at Guelma.

The sun's true altitude at Torreblanca on August 30, at 1h. 18·5m., may be taken as 54°·5. For this altitude the augmentation of the moon's semi-diameter is 14″·3. Adding this to the geocentric semi-diameter, 16′ 21″·4, as taken from the Nautical Almanac, 16′ 35″·7 is obtained for the apparent semi-diameter of the moon as seen from Torreblanca at mid-totality. Deducting from this the semi-diameter of the sun, namely 15′ 50″·7, we obtain 45″ as a sufficient approximation to the width of the annular band by which the disc of the moon overlapped that of the sun. Therefore, to an observer stationed on the central line in this neighbourhood, no protuberance could be visible at mid-totality which had a height less than 45″, and, neglecting the small displacement of Torreblanca from the central line, the protuberances of second contact, magnificent though they were, could not have exceeded this height.

Eight seconds before second contact I detected the streamers of the outer corona on the western limb of the moon. At this moment there was no trace of the inner corona, which presents to the spectator during the whole of totality the appearance of a bright, luminous ring surrounding the moon.

If we assume that the argument from parallax is applicable to the inner corona, as it is to the protuberances, we have to conclude that, eight seconds before second contact, the light-giving portion of it did not extend further than

between 93″ and 94″ from the western limb of the sun. To an observer on the central line, at mid-totality, it is eclipsed to a distance of 45″ from the sun's limb, and this would leave only between 48″ and 49″ as the width of the outer portion, which furnished the unexpected amount of light which persisted through totality. It is clear that if the inner portion, having a width of 45″, had been uncovered, the daylight during totality would have been still more remarkable.

In this respect there was a great contrast between the eclipse of this year and that of May 17, 1882, which I witnessed at Sohag, on the Nile, where a large camp of astronomers of many nations was established. In it, one of the most striking features was the rapid darkening during the last moments before second contact. I have always compared it to what is witnessed when a lecture-room is darkened during the day by quickly closing the shutters of the windows in succession. In 1882 the darkening took place rapidly and completely; and immediately quite a number of stars came out, besides the great comet which revealed itself, all unsuspected, close to the sun's limb, and formed the feature of that eclipse which was most noticed and is best remembered by the spectators. In 1905 the darkening effect was much less striking; but the illustration of the lecture-room holds if we imagine that the shutter of the last window is out of order, and has to remain open during the demonstration.

The contrast between the two eclipses is accentuated when we remember that the apparent semi-diameter of the moon, as seen from Torreblanca, was 45″ greater than that of the sun, while on the Nile this excess was only 15″·4. Therefore a width of 45″ of the brightest part of the corona was eclipsed in 1905, as against only 15″·4 in 1882. If, therefore, the uneclipsed coronas had possessed equal efficiency as furnishers of daylight, the darkness during totality ought to have been much greater in 1905 than it was in 1882; but the opposite was the case. Therefore, whatever may be the process by which the inner corona or luminous ring is produced, it was much more active on August 30, 1905, than it was on May 17, 1882.

December 9. J. Y. BUCHANAN.

The Engineer's Unit of Force.

IN his letter of November 16, your reviewer refers to the "apparent inability of academic writers to understand the engineer's position in this matter." May I, as an "academic writer," state that I have no difficulty whatever in understanding the engineer's position in regard to the gravitational unit of *force*. It is his treatment of *mass* that I do not understand. I am not quite sure whether it is worth while trying to understand it, as it always seems, somehow or other, not to be altogether satisfactory, and I have great doubts at present as to whether it is necessary.

I have always supposed that the great advantage of a gravitation unit of force was that it enables problems in motion under force to be treated *without* introducing the notion of *mass* at all, by means of the relation

$$\frac{\text{force on body}}{\text{weight of body}} = \frac{\text{acceleration produced by force}}{\text{acceleration of gravity}}.$$

Moreover, when we come to deal with mass, if we take a pound as the unit of mass and a pound weight as the unit of force, the numerical measures of the mass and weight of any body will be identical. This is surely simple, intelligible, and convenient.

But instead of this I find that engineers put $W/g=M$ and call M the mass of the body, and that they have adopted a unit of mass, called a slugg, based on this relation, which to my "academic mind" appears both meaningless and useless. If "people do not, and never will, think in poundals," still less will they think in sluggs, and a terminology involving this unit can scarcely be described as "not divorced from common thought and speech." I cannot think any reasonable engineer would expect to see tea and sugar sold by the slugg, and one thing I do not understand is whether, if this custom *were* adopted, I should get the same quantity of tea or sugar at London as at Johannesburg, or whether the grocer would be expected to make allowance for the variations in g.

If, on the other hand, the grocer retained the time-honoured custom of weighing out the sugar by the pound, it would appear that the engineer's estimate of the mass of the sugar depended, not only on the sugar itself, but also on his choice of units of length and time. In these circumstances it seems reasonable to ask whether the engineer still accepts or discards the conventional, but somewhat meaningless, definition of our text-books, "Quantity of matter is called mass."

Is not the writing of W/g equal to M a mere attempt to copy blindly the academic method of treatment, and to adapt it to a system of units to which it is ill-suited? Writing on a similar issue elsewhere, I pointed out on one occasion that I prefer to solve the problem of the three cats killing three mice by some method equivalent to the "rule of three," and not to adopt an artificial unit of cats in order to write the equation mice = cats × minutes.

G. H. BRYAN.

IT will be seen that Prof. Bryan, instead of defining force as the rate of change of momentum, or using the corresponding dynamical equation $F=Ma$, works problems in motion by means of a proportion, his equation being equivalent to $F=W/g\,a$; he thus avoids both the poundal and the slugg. This differs from the two absolute systems previously discussed in that W/g is not here a measure of mass, on account of the variable nature of the gravitational unit of force, as his weight and mass are numerically the same, while g varies with locality. A concrete example well illustrates this system. Suppose a body weighing 32·182 pounds at London to leave the earth under the action of an upward resultant force of one pound, and to travel through space with an acceleration of one foot per second per second. The value of g would continually decrease, but the weight (*i.e.* the gravitational force between the earth and the body) would in this system always be called 32·182 pounds, so that at the instant when g was reduced, say, 50 per cent., the acceleration force, though unchanged in amount, would be called two pounds, in order that Prof. Bryan's proportion should still be true. In fact, the pound force at this juncture would have only half its original absolute value, and would go on diminishing indefinitely; and this system is described as "simple, intelligible, and convenient." The beginner, introduced to dynamics in this fashion, as simply rule of three, with the conception of inertia designedly veiled, endeavouring to think in a variable unit, and with only one name for both force and mass, cannot be considered to have made a very auspicious start, and he may well be forgiven if he is never able to free himself from the tangle. The gravitational system, at any rate, must be ruled out of court.

In the everyday work of the engineer, mere inertia has seldom to be spoken or thought about, and I must still maintain that the engineer's system, with its new inertia unit, is "not divorced from common thought and speech." As a matter of fact, it is much easier to think of inertia in a distinct unit like the slugg than one the name for which is also used for force.

Prof. Bryan is evidently sincere when he says that he does not understand the engineer's treatment of mass. The operation of weighing is not a dynamical one. Inertia does not enter into the matter at all. It is a statical problem in the equilibrium of forces. If the inertia unit were here dragged in as suggested, Prof. Bryan fails to see that the specification in sluggs would be at least as definite as a specification in pounds; and it might be even more definite, for if the grocer in Johannesburg had studied dynamics in the variable gravitational unit, the weigher of the sugar might plausibly argue that, as "the numerical measures of mass and weight," in pounds, are "identical," he was quite justified in using an imported spring balance.

The present confusion is no doubt partly due to the substitution of the word mass for the good old word inertia. If mass means quantity of matter as determined by weighing, then inertia is probably, but not necessarily, proportional to mass. Readers who are interested in the subject may be referred to a correspondence which took place in NATURE about nine years ago (vol. lv.), and especially to letters by Prof. (now Sir) Oliver J. Lodge, Prof. John Perry, and Prof. G. F. Fitzgerald.

THE REVIEWER.

"Mathematics" applied to Chemistry.

IN his notice of my book "Researches on the Affinities of the Elements" in NATURE, November 16, the reviewer impugns the legality of applying mathematical formulæ to my surfaces. I trust I may be allowed to answer briefly my critic's objections. His difficulty as to the non-continuous nature is imaginary, and arises from a mistaking of the object to be achieved—which is simply to obtain either a surface or a mathematical expression from which *can* be deduced the affinities any one element exhibits for any other. This can be done from the formulæ, and they do, therefore, characterise the chemical properties of an element which depend upon these affinities. Although there exist an infinite number of points on the surface which are occupied by no element, yet there exist only a *finite* number of points the x and y coordinates of which are *whole* numbers, and to *every* integer value given to x and y in my formulæ there corresponds a definite element; so that, so long as we keep within the domain of integer numbers (as we are forced to do by the nature of the construction) continuity is attained.

The complexity of the formulæ is more apparent than real, because the only values which x and y can have are integer numbers, and the constant and many terms disappear in practice. GEOFFREY MARTIN.

Kiel, December 6.

IT is true that the plan proposed by Mr. Martin is occasionally used on the convention that only the values of the equations to the curve which occur at the integer points are to be used; but the reviewer still maintains that the principle is a false one. A curve is intended to exhibit *continuous* change, according to some law, and he is unaware that any result of value has ever been obtained by the use of the plan, except, perhaps, that of appealing to the visual sense. THE REVIEWER.

Heat a Mode of Motion in the Seventeenth Century.

THE following statement occurs in the "Medulla Medicinæ," by J. A. Van der Linden, Med. Prof., Franekeræ, 1642, p. 182:—

"Calor est minutissimarum materiæ partium motus in se reverberatus."

Van der Linden was a famous teacher, but the theory may not have originated with him. Are there other co-temporary anticipations of "Heat a mode of motion"?

W. R. GOWERS.

THE PULSE OF THE ATMOSPHERIC CIRCULATION.

SOME fifteen years ago an American eclipse expedition which included Prof. Cleveland Abbe visited St. Helena, and, on leaving represented to the Governor, Mr. R. L. Antrobus, now of the Colonial Office, the importance of establishing a meteorological observatory there. The representation was sent to the Colonial Office, and, the colonial finances being then in a depressed condition, the Colonial Office applied to the Meteorological Council for assistance.

It is needless to spend many words over the meteorological importance of such an enterprise. St. Helena emerges from the sea in the heart of the trade wind of the southern Atlantic. In no part of the globe, perhaps, is the trade wind current so persistent. The trade winds have long been recognised as primary factors of the atmospheric circulation. Speculation on their origin, which still forms the staple of the physical geography of the schools, carries us back to the writings of Halley and Hadley. The south-easterly current over St. Helena is the flow along the main artery of the never-failing atmospheric circulation, and at St. Helena if anywhere we may put our finger on the pulse of that endless and complex process of transformation of solar energy of which the weather of our islands and elsewhere is an expression.

The council, itself not wealthy, had a Robinson anemograph, then lately returned from duty in Heligoland. This was lent to the colony, and with it was found a small annual sum by way of payment for its curator, Mr. Hands, of St. Matthew's Vicarage, who undertook as well the duties of observer for a normal station of the second order, with instruments furnished by the council.

The anemometer continued its run with some unavoidable interruptions, and the observations were taken until the middle of 1904. There are besides observations of rainfall at other stations in the island.

By 1904 that part of the spiral of the direction pencil which had to record south-easterly winds became so worn by constant use that a hollow was formed there and the record had become an unsatisfactory one. With the assistance of the engineer officers stationed at St. Helena the matter was inquired into, and, as a result, the instrument was ordered home for repairs. At the same time an attempt was made in the observatory branch of the Meteorological Office to put together the results of the long run and to collate them with the other observations. I will not anticipate the publication of the results which, I hope, will follow in due course, but to one interesting side of them, too speculative for an official report and too suggestive to be altogether ignored, I would like to direct attention, because it shows a possibility (perhaps more) that with more searching we may find a working connection between the pulsations of the trade wind in the southern hemisphere and the general type of weather in so distant a part of the globe as our own islands.

While the trade winds may be regarded as the most obvious representative of the dynamical effect of solar energy, rainfall must be allowed to be also very closely connected with the process of distribution of that energy. The convection of heat by evaporation from warm water surfaces and condensation in cooler regions represents a process tending towards equalisation of thermal distribution on a gigantic scale. The main directions of transference are from south to north on the one hand, and generally eastward from sea to land on the other. The white snow coverings of the polar regions and the persistent rivers of great continents are permanent records of nature's endeavour to distribute more nearly equally over the globe the supply of solar heat. From a general point of view rainfall or snowfall in the temperate and arctic zones may be regarded as an index, perhaps a spasmodic one, of the general circulation from the tropical regions towards the poles, and to that extent as the counterpart or correlative of the kinetic energy of the trade winds which represent the flow towards the equatorial region. The transformation of energy in rainfall is on a vastly greater scale than that displayed by the trade winds. Supposing that the trade wind at St. Helena is a mile high, the energy represented by the year's flow in a slice of the current a mile in width would be about equal to that represented by a year's rainfall on a single square mile in the neighbourhood of London. Of these two indices of the general process of distribution of solar energy, the one is the steadiest, the other the most fluctuating of all meteorological phenomena, and any indication of an underlying relation between them, which is, in a way, a necessity of the general process of circulation, would be of great meteorological interest and might be of immense economic importance.

So far as I have carried it, the study is perhaps

merely tantalising, but I should like to present the case as it occurred. When the figures for the average wind velocity were being put together, I inquired about the variation from year to year. The monthly values had not been combined, and a glance showed the last year (1903) to be one of exceptionally high velocity. For the complete year, since calculated, it is twenty-one miles per hour; the average for the twelve years is eighteen miles per hour. I noted 1903 as the year of heavy rainfall in this country, and asked about 1893, the year of drought, especially in the spring months. I found the wind velocities at St. Helena were for the first half

Jan.	Feb.	Mar.	Ap.	May	June	
16	14	—	15	14	—	in 1893,

as against

Jan.	Feb.	Mar.	Ap.	May	June	
21	20	16	20	16	19	in 1903.

The first two are the lowest velocities of those months on record; the others are low, but not the lowest. The blanks mean that the instrument was not working properly. This suggested some sort of connection, a stronger trade wind being associated with a heavier rainfall in this country. I obtained the monthly values and plotted the several years' variation. There was unmistakable evidence of a large seasonal variation with a maximum in September and a minimum in May. I plotted the average seasonal variation of the St. Helena wind for the twelve years, and against it the seasonal rainfall in the south of England for thirty-five years, which I happened to have at hand. The curves are reproduced in the figure (Fig. 1). The similarity is surprising. Of course, the seasonal rainfall is not the same in all localities, even in the British Isles. Somewhat similar curves are, however, to be found for Stykkisholm, in Iceland, and for Hakodate, in Japan, so that the case was not quite an isolated one. I was, therefore, not without hope that the evidence for organic connection would develop with further investigation. When plotting the curves of wind velocity for individual years, I noted that 1898 was an exceptional year, because it had two maxima of wind velocity, one in March and one in October, instead of the usual single one in September. Some information that I had for Southampton seemed to indicate a similar state of things for rain in England (south) in that year. I had the monthly rainfall figures for England (south) computed for each year, and looked at once to those for 1898. Here are the figures for the two variables compared for that year.

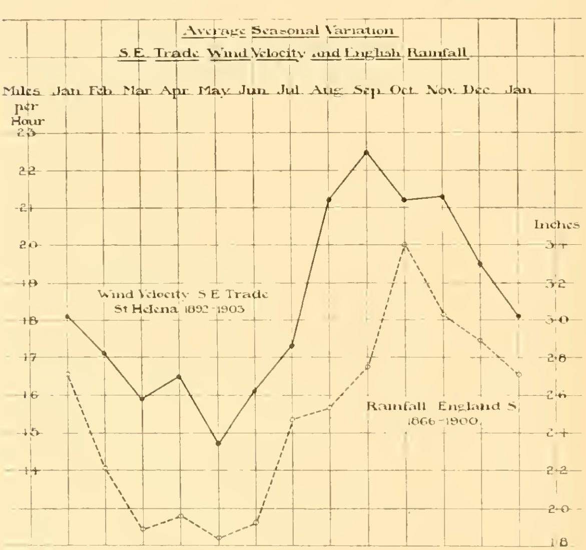

FIG. 1.

St. Helena wind velocity—

Miles per hour

Jan.	Feb.	Mar.	Ap.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
19	19	22	20	19	16	16	15	22	24	20	20

South of England rainfall—

Inches

Jan.	Feb.	Mar.	Ap.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
0·71	1·58	1·12	1·39	3·59	1·46	0·49	1·37	0·99	3·48	3·67	2·86

There is unmistakably the second maximum of rainfall. It is in May, generally the driest month, two months after the unusual second maximum of wind velocity at St. Helena. The ordinary autumnal maximum of rainfall is delayed a month until November, just as the wind maximum is delayed a month until October.

As a test case this seemed to be almost conclusive and the connection to be put beyond doubt, but in meteorological matters there are many disappointments. Some goblin seems to be in possession of this castle in the air; we see a glimpse of light; knock at the door; the goblin opens it almost wide enough to let us in, and then he slams it in our faces with a laugh. One can almost hear the mischievous Puck crowing to the

"Captain of our fairy band,
Helena is here at hand,
And those things do best please me
That befall preposterously."

There is even a faint echo of the wicked exclamation

"Lord, what fools these mortals be!"

When one turns from the average of years to the individual years, after the curious test case of 1898 one must confess that while the seasonal variation is maintained fairly well in the trade wind, year by year, one cannot recognise it in the rainfall. There appears, perhaps it is hardly necessary to say so, to be no regular seasonal variation in a single year of English rainfall. Any month may be the wettest month or perhaps the driest, and so a fitful parallelism is rudely interrupted by a wet July or some unaccountable abnormality. The phenomenally wet year, 1903, is truly the year of greatest trade wind velocity, but the order of wind velocity is not regularly the order of rainfall values; one wonders whether the recorder has always been working as one would wish; and when the monthly rainfall average is taken for the twelve corresponding years instead of the thirty-five years, the curious

subsidiary maximum in April so neatly reproduced in the St. Helena wind has disappeared, owing principally, be it said, to an abnormally dry April in 1893.

Yet the evidence in favour of a connection can hardly be pure coincidence. The little rain maximum in April is not mere illusion. The fact that a seasonal variation of rainfall does show itself in the average of a few years has a meaning, and that its phases are closely similar to those of the arterial pulsations of the general atmospheric circulation accords too much with what may be called common sense to be altogether devoid of significance.

Sooner or later we shall catch the nimble imp that jeers at us to-day, and, if I mistake not, when he is caught we shall make him tell us something of the real secrets of these atmospheric relationships.

There are two considerations that may be mentioned. A disproportionately large fall of rain is sometimes regarded as an accident of little or no influence upon general meteorological conditions, but in view of the enormous quantities of energy involved that view can hardly be seriously maintained. It is true that on some days we get thunderstorms with heavy rain distributed in a most irregular manner, and for these at present no satisfactory explanation can be given, but it should be looked for seriously. Secondly, the rainy movements of the atmosphere in this part of the world are, as already mentioned, a south to north movement and a west to east movement. Perhaps we may in time be able to disentangle the effects of the various causes and find the regular sequence at present overlaid by the influence of secondary disturbing causes.

I have ventured to put forward these suggestions, which I frankly confess are deplorably bizarre, because my readers may have at their disposal methods, that I am ignorant of, by which a crucial test may be applied to the question whether there is any definite and, shall I say, useful connection between the pulsations of the south-east trade wind and the rainfall of north-western Europe.

W. N. SHAW.

TWO BOOKS ON ANIMAL BIOGRAPHY.[1]

IN the second of these two works the author expresses the opinion that the first question which will be asked by the reader is whether the various anecdotes are strictly true. The question that presents itself to our mind is whether such books will be read at all, and if so by whom? The professional naturalist, we dare venture to say, will have nothing to do with them; they are not apparently intended for children, and for our own part we confess that to read them for either pleasure or instruction is about the last thing we should think of doing. They are what may be called "animal novels," and thereby differ to a considerable extent from the old-fashioned "animal biographies," under which heading we have, however, ventured to include them. In each instance the author takes a number of more or less well-known animals, and recounts their ordinary everyday life, so far as it can be interpreted, Mr. English giving this for the most part in what are supposed to be the creature's own words, while the American author mingles verbal with descriptive narrative. Both works are, no doubt, excellent in their own particular way; and, for the sake of authors and publishers alike, we trust that a sufficient number of readers exist to whom this style of writing appeals with infinitely greater force than it does to ourselves. To such we may commend each of the two works, for, in the respective subjects, we find little to choose between them.

Mr. English, very appropriately, confines himself to British animals (including mammals, birds, fishes, insects, &c.); and although we cannot congratulate him on the title he has selected for his volume, we are pleased to be able to record our high appreciation of his skill as a photographer, and of the excellent manner in which his pictures have been reproduced.

FIG. 1.—The Wood-mouse. From English's "Beasties Courageous."

The photograph of the wood-mouse herewith presented to our readers is absolutely exquisite, and cannot be surpassed. Moreover, it is by no means a solitary example of excellence, every picture in the book being of high quality, although some are, of course, better than others. As a picture-book of various types of British animal life the book would be hard indeed to beat.

Mr. Long, on the other hand, takes for his subject some of the more striking animals of the Arctic districts of North America, which he calls for the most part by their native Indian names, after the manner of "Hiawatha."

The first six chapters are, for instance, devoted to the white wolf, under the title of "wayeeses, the strong one"; but it is a little remarkable to note that in the glossary at the end of the volume this name is spelt "wayeesis." Other chapters follow on the wild goose ("waptouk"), the fisher-marten ("pequam"), the salmon, &c. All bear the impress of truth, and relate the experiences of one who has seen the animals in their native wilds. The most striking incident is perhaps the one depicted on the cover of the book, where the author had the good fortune

[1] "Beasties Courageous; Studies of Animal Life and Character." By D. English. Pp. viii+121; illustrated. (London: Bousfield and Co., Ltd., 1905.) Price 5s. net.

"Northern Trails; some Studies of Animal Life in the Far North." By W. J. Long. Pp. xxv+390; illustrated. (Boston, U.S.A., and London: Ginn and Co.). Price 7s. 6d.

to see a wolf spring at night upon a jutting crag, where, silhouetted by the full moon behind, it gave vent to its "terrible howl." The illustrations in this volume are by that well-known artist Mr. C. Copeland, whose facile and truthful style stands in no need of any commendation of ours. These illustrations render Mr. Long's volume an attractive book for the drawing-room table at this season of the year.

SECONDARY SCHOOLS AND ENDOWMENTS.

AN INTERESTING TRANSFER SCHEME.

A SOMEWHAT novel proposal has been formulated for the transfer of an endowed school, with its property and funds, to an "education authority" other than a Local Education Authority under the Education Acts of 1902–3. This proposal relates to the Subordinate School at Rugby.

It appears that, for some time, there has been a movement in the locality with a view to the establishment of a technical school so as to organise systematically the scattered forces already at work. The Warwickshire County Council offered a grant of 1000*l.* towards the erection of such a school, while the governing body of Rugby School offered 500*l.* and a site on the grounds of the Subordinate School for the same purpose. These offers, however, failed to secure adequate local agreement—hence the above-mentioned transfer proposal.

According to the notice in the *London Gazette*, the governing body of Rugby School will apply to Parliament for an enabling Act "for the establishment, constitution and incorporation of an 'education authority,'" to whom that governing body may transfer the Subordinate School with its property and funds, and to whom they may make annual or other payments or contributions. This "education authority" would contain representatives of the governing body of Rugby School and of other local bodies (*e.g.* the County Council of Warwickshire, the Urban District Council of Rugby); any doubts or questions which might arise between the various bodies represented would be determined by the Board of Education. The "education authority" is to conduct the school "as a school for higher or secondary education . . . shall afford a good commercial education for students . . . and shall maintain the teaching of English, Latin, at least one modern foreign language and Greek, unless and until the governing body" (*i.e.* the governing body of Rugby School) "shall consent to the discontinuance of Greek." Other conditions relate to (1) the maintenance, by the governing body of the Rugby School, for the benefit of the students of the Subordinate School, of the existing system of major foundationerships at Rugby School; (2) the continuance of the engagements of the existing staff of the Subordinate School; (3) the borrowing, upon the security of the trust property, by the "education authority" of such sums for additions, improvements, &c., as may be needed—these powers to be subject to the conditions imposed by the Board of Education; (4) the maintenance at the Subordinate School, by the "education authority," of the existing system of foundationerships and scholarships tenable at that school.

A good deal of misgiving has been manifested locally in regard to the foregoing proposal, but it seems to us to be a step in the right direction. We confess that, as to nomenclature, the words "education authority" do not commend themselves to us as a suitable description of the new body to whom it is proposed to make the transfer. But the objects which may be secured under the proposal now foreshadowed are great indeed. To have obtained a gift which, if capitalised, would amount to between 50,000*l.* and 70,000*l.*, and to be enabled to utilise such resources to promote the educational and industrial progress of the town and neighbourhood of Rugby, are matters for sincere congratulation. The representative character of the new "education authority" will ensure the quickening of an intelligent interest in, and zeal for, that technical and higher education which the townsfolk of Rugby are seeking—including the actual provision of a technical school.

It is rather difficult to appraise rightly the action of those who have been disposed to reject an arrangement which, as we hope, is now about to be consummated. Possibly, upon reflection, they will become conscious, as has been the case with other erstwhile opponents, of the opportunities that are within their grasp. For this transfer provides not only that ladder which educationists are so anxious to erect for all those who can climb it, and who may thus be equipped for their several callings, but it will provide also an excellent object-lesson in regard to educational endowments and their administration for the public welfare. With potential issues like these, it is to be hoped that the inhabitants of Rugby and the neighbourhood will brace themselves for an effort in educational administration which shall inspire other localities to grapple earnestly with more exacting conditions.

NOTES.

LIEUT.-COLONEL PRAIN, I.M.S., F.R.S., took up the duties of director of the Royal Botanic Gardens, Kew, on December 16. Sir W. Thiselton-Dyer will continue to take charge of Government advisory work until March 31 next.

AT an Investiture held by the King on Monday, Prof. G. H. Darwin was invested with the insignia of a Knight Commander of the Order of the Bath (K.C.B.), and Sir Felix Semon with those of a Knight Commander of the Royal Victorian Order. His Majesty subsequently decorated the commander, officers, and several other members of the National Antarctic Expedition with the medal in commemoration of the expedition.

A SERIES of meetings for the informal discussion of important contributions to meteorological literature, particularly those by colonial or foreign meteorologists, has been arranged at the Meteorological Office by the director, Dr. W. N. Shaw, F.R.S. Two meetings have already been held, and seven others will be held from January to April of next year. The subjects suggested for discussion are of great interest to students and investigators of meteorological problems, and the director invites exchange of views upon them.

THE next meeting of the French Association for the Advancement of Science will be held at Lyons from August 2 to August 7, 1906, under the presidency of Prof. Lippmann.

WE regret to see the announcement that Mr. Lewis Wright, author of well known books on "Light" and "The Induction Coil in Practical Work," and of several works on the scientific breeding of poultry, was accidentally killed by a passing train at Saltford railway station, near Bristol, on Saturday, December 16.

A LARGE and influential committee of leading representatives of science in many parts of the world has been formed with the object of placing a monument to the

memory of the late Prof. Ernst Abbe at Jena between the Volkshaus erected by him and the optical works to the development of which he devoted his life. Zeiss instruments are in themselves monuments to Abbe's work wherever they are used, but there are probably many men of science who will welcome the opportunity of contributing to the establishment of some permanent representation of his personality in the place which he made famous. Subscriptions in support of the scheme should be sent to Dr. Gustav Fischer, Jena.

AMONG the letters from the honorary members of the Essex Field Club read at the meeting at Chingford on December 9 and referred to in our last issue (p. 157) was a very appreciative one from the veteran naturalist Dr. Alfred Russel Wallace, who had been attached to the club from the period of its foundation, and who had lectured at its meetings and taken part in many of the excursions and discussions. It is of interest to note that Dr. Wallace gave a preliminary account of his work on insular faunas and floras, being the substance of his book "Island Life," at a meeting of the club on January 4, 1881. In his recently published life he refers also to the fact that before his departure for America in 1886 he gave the club a lecture on the subject of variation, one of the chapters of his subsequent work on "Darwinism."

PROF. MELDOLA, F.R.S., presided over a "science dinner" given by the Maccabæans on December 16. After the loyal toasts, the chairman said the Maccabæans are a society composed primarily, though not entirely, of Jewish professional men, bound together by ties of race and religion. This race has contributed much to the advancement of philosophy and of science. It is the race which gave Maimonides and Spinosa to philosophy, the Herschels to astronomy, Ferdinand Cohn to botany, the Meyers and many others, including Brühl, to chemistry, and Lippmann and Herz to physics. Prof. Meldola concluded by giving the toast of "Science," coupled in the first place with the names of the representatives of scientific institutions represented in the room, and afterwards with individual representatives. Sir W. Huggins, F.R.S., and Sir A. Geikie, F.R.S., responded for the Royal Society, the Duke of Northumberland for the Royal Institution, Major P. A. MacMahon F.R.S., for the British Association, Mr. J. J. H. Teall, F.R.S, for the Geological Survey, Sir J. Evans, F.R.S., for anthropology, Sir Henry Roscoe, F.R.S., and Sir William Ramsay, K.C.B., F.R.S., for chemistry, Prof Poulton, F.R.S., for biology, Prof. Starling, F.R.S., for physiology, and Prof. Ayrton, F.R.S., for applied science.

SEVERAL subjects of scientific interest were discussed at the conference on smoke abatement and the exhibition of smoke-prevention apparatus held on December 13–15 in the hall of the Horticultural Society, Westminster. The inaugural address was to have been delivered by Sir Oliver Lodge, F.R.S., but he was prevented by indisposition from attending. Some manuscript notes by Sir Oliver Lodge were read to the meeting by Sir William Richmond. These notes dealt with fog as a destructive agent, and the proposal that smoke and fog should be precipitated by electrification of the air. The right way to deal with a town fog, according to the author, was not to produce it. The connection between fog and the imperfect combustion of solid fuel was then illustrated, and the need for improved methods of burning fuel insisted upon. At the same meeting the question, "Is London fog inevitable?" was discussed by Dr. W. N. Shaw, F.R.S. On the second day numerous papers were read, and of these may be mentioned stoking and smoke abatement, by Commander W. F. Caborne; the abatement of smoke in factories, by Dr. Rideal; the artificial production of persistent fog, by the Hon. Rollo Russell; destructive effects of smoke in relation to plant life, by Miss Agar and Mr. A. Rigg. At the third meeting of the conference Sir John Ure Primrose made a plea for a systematic analysis of the air of towns. He said that samples of the rainfall collected in Glasgow now show no traces of free acid, whereas only a few years ago similar samples were found to be strongly acid. This improvement in the city's atmosphere is due chiefly to the check the Alkali Acts have imposed upon the emission of acid gases by chemical and metallurgical works. The exhibition of smoke-abatement appliances included grates, stoves, cooking plant, heating flues, chimney construction, and smoke-consuming and smoke-preventing apparatus.

IN the note on the contents of the *Zeitschrift fur wissenschaftliche Zoologie*, vol. lxxx., part ii., published in our issue of December 7, Mr. S. Hlava's paper is stated to have been on the Radiata, instead of the Rotifera.

"THE Formation of Local Illustrative Collections in Museums" is the title of an article by Mr. J. Maclauchlan, of Dundee, in the October issue of the *Museums Journal*, which may be commended to the best attention of the governing bodies of provincial institutions of this nature, who, in many cases, are too apt to convert them into mere "curiosity-shops," or who attempt to usurp the functions of large museums by the display of a more or less ill-arranged general natural history collection. The rating of museums and public libraries is another question discussed in the same issue.

THE most interesting announcement in part iii. of the first volume of the *Journal of the Federated Malay States Museums* is, perhaps, the identification of a tooth of the Indian Pleistocene *Elephas namadicus* from Perak. Dr. C. W. Andrews being responsible for the determination, there can be no reasonable doubt as to its correctness; and this being so, the matter is of considerable interest as tending to link up the extinct proboscidean fauna of India and Burma with that of Borneo, Java, and Japan. In the same issue Mr. Bonhote describes a new rat, Mr. Ogilvie-Grant a new whistling-thrush, and Mr. H. C. Robinson a new tree-partridge, all from the Malay Peninsula or adjacent islands.

THE greater portion of the November issue of the *Quarterly Journal of Microscopical Science* is devoted to three instalments of a long paper on the formation of spicules, the author, Mr. W. Woodland, dealing in this instance with calcareous sponges, Alcyonium, and the sea-urchin larva. The relation of triradiate spicules to the dermal cells to which they owe their origin is beautifully illustrated in the plates, and it is shown that, as in the case of the simpler types, the triradiate form is directly related to the conformation of the secreting agency. As to the use of these triradiate spicules, it is pointed out that the hollow cylinders of which sycon-sponges consist are liable to be swayed by the movements of the water, and that were these oscillations to become excessive the organism would be injured. Moreover, as the oscillations are both vertical and horizontal, support in each of these directions is essential. "Both of these elements are supplied by the numerous triradiate spicules contained within the sponge-wall, for it invariably follows from their conformation that if one ray be vertically disposed, then the two companion rays will lie in lines only deviating from the horizontal

by an inclination of 30°, and hence the three rays practically constitute two axes, respectively lying in the required vertical and horizontal directions." It will be remembered that in a recent note we referred to the views of an author who regarded these triradiate spicules as an instance of over-specialisation.

THE *Journal of Economic Biology* is the title of a new serial, edited by Mr. W. E. Collinge, and published by Messrs. Dulau and Co. For some time, and more especially since the foundation of the Association of Economic Biologists, it has been evident that workers in the subject to which the new serial is devoted frequently experience difficulty in finding suitable means of making their labours known to the public, especially when illustrations to their papers are required, and it is to meet this want that the venture, to which we wish cordial success, has been made. In the opening article Prof. A. H. R. Buller discusses the destruction of wood-paving in roadways by a kind of dry-rot produced by the fungus known as *Lentinus lepideus*. In the second article the editor describes some very remarkable varieties of the currant-moth produced by change of food and temperature, while in the third and last communication Mr. F. V. Theobald describes new gnats from various parts of the world.

WITH the October issue the publication of *Climate* came to an end, an amalgamation having been effected with the *Journal of Tropical Medicine*, which in future will devote four of its issues annually to the special subjects hitherto dealt with in *Climate*.

THE *Journal of the Royal Sanitary Institute* for December (xxvi., No. 11) contains the second part of a paper on the administration of the Food and Drugs Acts by Mr. Wellesley Harris which should be very useful to students of public health, the mortality statistics of boot and shoe workers in Northampton by Dr. Beatty, a note on the recent literature of plague by Colonel Notter, and an article on school hygiene by Dr. Elkington.

IN an interesting article on the revival of phrenology in the *Fortnightly Review* for December, Mr. Stephen Paget reviews the subject and refers to Dr. Bernard Höllander's book on the mental functions of the brain. Gall it was, celebrated for his anatomical studies of the brain, who originated what is known as phrenology, a study very different from the present conception of localisation of function in the brain, as Mr. Paget points out. From the wreck of Gall's work Dr. Höllander has saved many well recorded cases of localised injury or disease of the brain with exaggeration or diminution of this or that one function—cases such as led to the discovery of the speech centres. But when Dr. Höllander asserts that his book may have an important bearing on the development of mental science, on the treatment of lunacy, &c., Mr. Paget considers that he is claiming much more than can be admitted.

ON the subject of the conditions essential to the best production of Para rubber, Mr. H. Wright has compiled some useful data in vol. iii., No. 6, of the Circulars of the Royal Botanic Gardens, Ceylon. It would appear that richness of soil is not so important as altitude and temperature, since by the annual shedding of its leaves the tree returns a large amount of material to the soil. With regard to temperature, the trees thrive best in Brazil in a mean temperature about 25° C., while, as to altitude, the limit of successful cultivation in Ceylon is placed at 2000 feet above sea-level.

THE superintendent of the botanical department, Trinidad, in the Bulletin (October) refers to a new variety of coffee, *Coffea robusta*, received from the Congo River, West Africa, that has been successfully propagated at the experiment station. A stock of nearly two thousand plants offered for distribution was quickly disposed of to planters. In the same journal Mr. W. R. Buttenshaw, writing on the subject of selection by means of vegetative propagation, instances a few of the improvements that have been effected by continuous selection of cuttings and by bud selection. A distinction is drawn between the sudden emergence of a sport and gradual development by careful selection.

WITH the object of ascertaining whether a commercial fibre can be prepared from banana leaf-sheaths, it is announced in the *Agricultural News* (October 21) that prizes for the best samples of fibre will be offered at the agricultural show to be held in the course of this month in Barbados; the fibre will be extracted from the dwarf banana, as this is the species cultivated there. In the last number of the journal, which, owing to an alteration in the sailings of the Royal Mail steamers, is dated November 11, a note appears on the cigarette and biscuit beetles. The former, *Lasioderma serricorne*, does not confine itself to tobacco, but feeds also on leather and drugs, and the biscuit beetle, *Sitodrepa panicea*, shows similar tastes.

THE report for the year 1904 of the director of the botanic gardens in Sydney, New South Wales, has been received. Amongst the list of interesting plants that have flowered during the year are *Diplachne Peacockii*, an indigenous grass recently discovered, *Paspalum cochinchinense*, another grass that, judging from the vigorous growth made in a dry season, may prove as valuable for fodder as *Paspalum dilatatum*, *Eucommia ulmoides*, the Chinese rubber-tree, and a number of Opuntias that are being cultivated with the object of obtaining a spineless plant. Of the trees planted in the Centennial Park, the most interesting are the Aleppo pines, *Pinus halepensis*, that are being grown as a wind-break.

IN the *Engineer* of December 15 drawings are given of a dredger that has been used by the Dundee Harbour Trustees for more than a century. It is built of oak, and is 68 feet long with a beam of 21 feet, and draws in working order 7 feet 6 inches. The engine is believed to have been built by James Watt.

IN the December number of the *Popular Science Monthly* there is a useful article by Prof. R. D. George, of the University of Colorado, giving an able summary of the existing knowledge of mining and the use of metals by the ancient Egyptians. In the same issue Dr. Charles R. Eastman, of Harvard University, inquires into the rightfulness of regarding Anaximander, the pupil of Thales in the sixth century B.C., as the first who foreshadowed modern ideas of evolution. All estimates present Anaximander as a keen and deeply contemplative student of nature who arrived at a dim adumbration of great truths.

IN the current issue of the *Bulletin de la Société d'Encouragement* Messrs. G. Arth and P. Lejeune give some interesting particulars of a prehistoric mass of metal found near Nancy at a depth of $4\frac{1}{2}$ metres below the surface. The mass weighs about 300 kilograms, and is accompanied by fragments of charcoal and slag. It appears

to have been the base of an ancient hearth in which the metal had been subjected to repeated and prolonged heatings. The metal contains, in addition to iron, 1·212 per cent. of combined carbon, 0·038 per cent. of graphite, 1·670 per cent. of silicon, 0·026 per cent. of sulphur, 0·013 per cent. of phosphorus, and 0·180 per cent. of manganese. It is thus a steel containing a higher percentage of silicon than is now usual. The microscopic examination shows that it belongs to Guillet's first group of silicon steels, pearlite steels consisting of a solid solution of Fe_2S in iron. In the same issue Mr. A. Porlier gives details of the composition of a cast-iron cannon ball found in making the underground railway through the old moat of the Bastille. The cannon ball was absolutely compact, but oxidised throughout, its specific gravity being 4·854 instead of 7·6 as is usual for cast-iron. Under the microscope the cementite appeared in brilliant lines, showing that it had completely preserved its metallic state. The oxidised portions, appearing as black masses, were derived from the pearlite, which in admixture with cementite constitutes ordinary white pig-iron. Analysis yielded:—water, 2·9 per cent.; carbon, 5·9 per cent.; silicon, 0·25 per cent.; manganese, 0·75 per cent.; iron, 72·0 per cent.; and oxygen, 17·45 per cent. The complete oxidation of the cannon ball, without any exterior deformation or fissuration, shows the intense action of diffusion during a century, and enables us to understand how the changes of rocks by metamorphism have been able, thanks to the intervention of infinitely longer periods, to give rise to new rocks of a homogeneous structure.

IN No. 50 of the *Bulletin du Musée océanographique de Monaco* Prof. H. Hergesell gives an interesting account of the method employed by the Prince of Monaco in the North Atlantic last April for ascertaining the conditions of the upper air by means of unmanned balloons sent up from his yacht. Two closed india-rubber balloons were employed; at a certain altitude the upper balloon bursts, or is set free by a simple electrical arrangement, when the lower one, which carries the recording instruments, falls, but has a float attached to it, at about 50 metres below it, and when this reaches the surface of the ocean the balloon is carried along by the wind at a height of 50 metres, and then the yacht has to chase it at full speed. Out of five cases specified by Dr. Hergesell, only one of the balloons eluded the pursuers. Of course, such a procedure can only be undertaken by a vessel having no other object in view, and it is necessary that the air should be clear, and that the velocity of the wind should not exceed the speed of the ship. Such experiments are exciting, but expensive; but some useful results at high altitudes were obtained.

A REMARKABLE dam is under construction at Niagara Falls, where the commissioners of Victoria Park, on the Canadian side of the river, have erected a column of concrete 50 feet high and 7 feet 4 inches square. This column of concrete was built on a trestle that stands 20 feet above the ground-level, and after the material is thoroughly dry the column is to be tipped over into the river to form a dam. The necessity for this work arose from the fact that the City of Niagara Falls, Ontario, and the Niagara Falls Park and River Railway, made complaint to the park commissioners that the works of construction for power development had lowered the water in the joint intake. The approximate weight of the concrete column is 200 tons. Every 8 feet of its height a wooden wedge is inserted in the side, and passes nearly to the centre, each wedge being about 12 inches thick on the outside, tapering to about 6 inches near the centre. The object of these wedges is to break the column into six pieces when it is tipped over. However, these sections will not be allowed to be caught by the current, for running up through the centre of the column there is a very heavy chain, the weight of which is about 800 lb. The purpose of this chain is to hold the sections together when the column is broken in falling. When it is prostrate, the top of the column will be 20 inches above the ground-level, and is expected to raise the water in the intake considerably. The intake is only about 600 feet up from the brink of the Horseshoe Fall, but the dam

FIG. 1.—A column of concrete built to be tipped over to form a dam at Niagara Falls.

will not affect the flow of the waterfall at that point. When dry, the column will be tipped by operating jacks under the base of the trestle, and when it tumbles it is expected to fall a little up-stream.

WE have received from Messrs. R. and J. Beck, Ltd., a copy of their new illustrated price-list of telescopes. The list contains particulars of numerous astronomical and naval telescopes, object glasses, spectroscopes, transit instruments, small observatories, diffraction gratings, &c., and will be found to be very useful and suggestive to any amateur astronomer who wishes to add a good instrument to his equipment; some of the portable mountings, both equatorial and altazimuth, appear to be very compact and useful. A copy of a photograph of the iron spectrum, taken with a "Thorp" transmission grating, shows the suitability of these replicas for high-class work, and Messrs. Beck undertake to mount the grating copies either on parallel plate glass or on prisms of any desired angle. All kinds of surveyors' instruments are also quoted in this list.

THE results of an interesting research on the selective reflection, by various crystals, in the infra-red spectrum are published by Mr. J. T. Porter, of Johns Hopkins University, in the November number of the *Astrophysical Journal*. It has previously been shown by Prof. E. F. Nichols that in the neighbourhood of $8 \cdot 5\,\mu$ the reflection from quartz is twenty or thirty times greater than in other parts of the spectrum, so that after three reflections from such a surface the spectrum practically contains only radiations of that wave-length. The wave-lengths of the "Reststrahlen," or the rays remaining after reflection, have already been determined for seven other substances by previous workers, and Mr. Porter examined fourteen additional crystalline compounds and found that at least seven of them exhibited unmistakable maxima in various parts of the spectrum. The radiometer and the method employed are fully described and illustrated in his paper, which also shows the energy curves of the spectra of the reflected radiations. The list given for nine of the substances tested shows that the wave-lengths of their "Reststrahlen" vary from $2 \cdot 30\,\mu$ for copper sulphate to $10 \cdot 31\,\mu$ for potassium dichromate.

MESSRS. WHITTAKER AND CO. have published a third edition of Mr. Joseph Poole's "Practical Telephone Handbook." The new edition has been entirely re-written and greatly enlarged.

WE have received from the superintendent of Government printing in India two volumes of the agricultural statistics of India for the years 1899–1900 to 1903–1904. The statistics have been compiled in the office of the Director-General of Commercial Intelligence. The first volume is concerned with British India, and the second with the native States. The volumes will prove of value to statisticians interested in Indian agriculture.

"WHO'S WHO" and the "Who's Who Year-book" for 1906 have now been issued by Messrs. A. and C. Black. "Who's Who" is a familiar work of reference everywhere; its price remains the same, 7*s*. 6*d*. net, but the volume has been enlarged by the addition of eighty-two pages. Interesting additions are made this year to many of the biographies by a record of the number of a person's sons and daughters. Motor and telephone numbers and telegraphic addresses have been added where requisite. The biographical notices of Fellows of the Royal Society and other men of science contained in the volume are of particular interest to us. This indispensable reference book is admirably supplemented by the year-book with its conveniently arranged tables, among which are to be found lists of the learned societies and university professors.

OUR ASTRONOMICAL COLUMN.

DISCOVERY OF A THIRD NEW COMET, 1905*d*.—A telegram from the Kiel Centralstelle announces the discovery of yet another new comet. Apparently the proximity of this object was discovered from the appearance of its image on a photographic plate exposed on November 29, and examined subsequently. The discovery was made by Mr. Slipher at the Flagstaff (Lowell) Observatory, and the position of the comet on November 29d. 9h. 27m. (Flagstaff M.T.) was found to be

R.A. = 22h. 44m., dec. = $11^\circ\ 18'$ S.

This is situated in the constellation Aquarius, about half-way between λ and τ Aquarii.

The daily movement in R.A. is given as $-1^\circ\ 33'$, or 6m. 12s., and in declination as $+25'$. From this it will be seen that the comet was at that time travelling in the direction of the constellation Aquila.

COMETS 1905*b* AND 1905*c*.—An observation of comet 1905*b*, made by Prof. E. Millosevich on December 13, gave corrections of -2s. and $-2' \cdot 3$ to the ephemeris published in No. 4057 of the *Astronomische Nachrichten*. The observed magnitude was 11·5.

The following set of elements for the orbit of comet 1905*c* have been computed by the discoverer, M. Giacobini, and, together with an ephemeris, from which an extract is given below, is published in the *Comptes rendus* for December 11:—

T = 1906 January 31·620 (Paris).

$$\left.\begin{aligned} \omega &= 171^\circ\ 23' \cdot 7 \\ \Omega &= 89\ \ 42 \cdot 0 \\ i &= 42\ \ 44 \cdot 3 \end{aligned}\right\} 1905 \cdot 0$$

$$\log q = \bar{1} \cdot 72728$$

Ephemeris 12h. (M.T. Paris).

THE RECENT AURORA AND MAGNETIC DISTURBANCES.—From an account published in the current number of the *Observatory*, we learn that on November 15, the date of the recent great display of the aurora, the greatest disturbance of the Greenwich magnets which has been recorded during the present year took place. All three elements were affected, a deflection of about 40′ being recorded by the declination-needle at 9 p.m. Of the two considerable streams of sun-spots which appeared near to the place of the great October spot (October 14–27), the one was a little ahead of the central meridian and the other not quite up to it at the time of the disturbance.

PHOTOGRAPHS OF JUPITER'S SIXTH AND SEVENTH SATELLITES.—At the meeting of the Royal Astronomical Society held on November 10, the Astronomer Royal exhibited and explained some photographs of the sixth and seventh satellites of Jupiter, obtained with the 30-inch reflector of the Thompson equatorial at Greenwich.

The results of the provisional measures of the photographs, and their comparison with the angles and distances given by Dr. Ross's ephemeris, the dates, and the exposures are given in No. 1, vol. lxvi., of the *Monthly Notices*. The exposures for the seventh satellite varied from 17 minutes to 177 minutes.

THE INTRINSIC LIGHT OF THE CORONA.—Employing a modified "Mascart" photometer, M. Chas. Fabry determined the relative brightness of the intrinsic light of the corona during the recent total eclipse of the sun. As a result, he found that at a distance of 5′ from the edge of the sun, and in the neighbourhood of the solar equator, the light of the corona has an intrinsic value of about 720 candle-power. Comparing this with the mean intrinsic value of the light of the full moon (viz. 2600 candles), he obtains the ratio 0·28 : 1, a value which confirms Prof. Turner's ratio of 0·25. To illustrate the great difficulty which attends the photographing of the corona in full sunlight, M. Fabry compares the value he thus obtained with the accepted value for the brightness of the sky near to the sun, and arrives at the conclusion that even the most brilliant parts of the corona are probably some 2000 times less bright than the sky on which they are projected (*Comptes rendus*, No. 23).

SUGGESTED NAME FOR NEPTUNE'S SATELLITE.—Writing to the *Observatory*, M. Fouche suggests that Neptune's satellite should be named after the most renowned of Neptune's sons, *i.e.* Triton. He states that this name has already been used for designating the satellite by several well known astronomers.

THE "COMPANION TO THE OBSERVATORY," 1906.—As in former years, the well known "Companion to the Observatory," published by Messrs. Taylor and Francis at 1*s*. 6*d*., contains all the data that an ordinary astronomer is likely to require in the briefest and handiest form. Messrs. Denning, Maw, and Lœwy have again provided the data referring to "Meteor Radiants," "Double Stars," and "Variable-star Ephemerides" respectively, and Dr. F. E. Ross's ephemeris for Jupiter's sixth satellite is given amongst the other tables which deal with the satellites of the major planets.

HYDROLOGY IN THE UNITED STATES.

WE have referred on previous occasions to the very complete way in which hydrological research is carried out in the United States, and to the value of the reports that are made from time to time by the officers having charge of the works.[1] We have been favoured with twenty-five further reports recently issued. The greater part of these refer to the water resources, and to the surveys being carried out by the departments in the different States. These are principally of local interest, although they contain a great deal of information useful to those engaged in water supply. Some of these reports, however, relate to matters that are of more general interest.[2]

Paper 119 contains an index to the hydrographic progress reports, 1888–1903, and paper 120 a review and index to papers relating to underground waters published by the United States Geological Survey, 1879–1904.

Report No. 110, on the hydrology of the eastern United States, contains twenty-three short papers by nineteen geologists and physicists connected with the eastern section of this division of hydrology. The most interesting of these papers is that which relates to the methods used in measuring the velocity, direction, and quality of underground water.

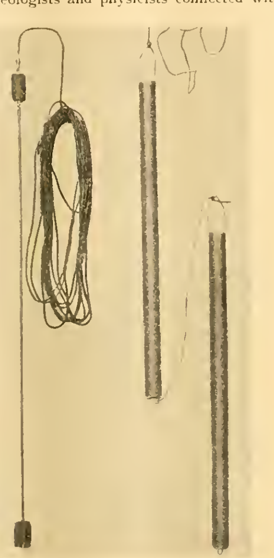

FIG. 1.—Electrode and perforated brass buckets used in charging wells.

The Discharge of Sewage into Porous Strata.—In one of the papers, by S. W. Callie, is recorded the experiments made to ascertain what would be the effect of discharging town sewage into pervious strata on the water supply of the neighbourhood drawn from wells.

The town of Quitman derives its water supply from a well in the limestone at a depth of 123 feet from the surface. A section of the soil shows 2 feet of surface sand, 60 feet of clay, 15 feet of sand, and 43 feet of water-bearing limestone.

The authorities of the town were seriously considering the question of disposing of the town's sewage by means of deep wells into the porous strata. The writer of the paper was engaged to report as to what effect this would have on the water supply. For this purpose he adopted the chlorine process. Seven wells in the locality were selected for making the experiment, the water in which was found to stand at a lower level than that in which the chlorine was to be introduced. Samples were taken from these wells, and the normal amount of chlorine determined. Two tons of salt were then put into the test well in the form of solution during a period of five days. Special precautions were taken in the method of introducing the salt to ensure complete saturation of the water. The normal chlorine at the well from which the water supply for the town was drawn was 5·44 parts in a million. Four hours after the introduction of the salt in the test well the chlorine began to increase, reaching a maximum of 6·80 parts in twelve hours, and continued to show an excess during the five days, after which it

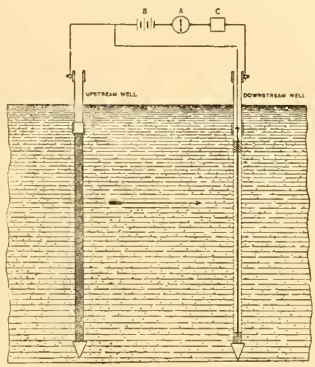

FIG. 2.—Diagram illustrating electrical method of determining the velocity of flow of ground water. The ground water is supposed to be moving in the direction of the arrow. The up-stream well is charged with an electrolyte. The gradual motion of the ground water toward the lower well and its final arrival at that well are registered by the ammeter A. B is the battery, and C a commutator clock which is used if A is a recording ammeter.

gradually subsided to its normal quantity. At two of the other wells a similar excess of chlorine was found, but at the other wells no change in the character of the water took place.

The general conclusion arrived at was that if sewage were discharged into the water-bearing strata it would contaminate all the wells in the locality that had a depth of 120 feet or more, and that if the proposed scheme of the municipality had been carried out it would probably have resulted in a serious epidemic.

Measurement of Underground Currents.—A paper by Charles S. Slichter gives a description of the underflow meter used in measuring the velocity and direction of underground water.

For the purpose of measuring the underground flow in any locality test wells are sunk consisting of 1½-inch or 2-inch tubes. These pipes are in lengths of 6 feet or 7 feet, with long threads and heavy wrought nipples. The well points are 4-feet brass jacket points of wire gauze. The tubes are driven with a ram weighing from 150 lb. to 250 lb., the movement of the tube being aided by a water jet. Four wells were driven from 4 feet to 6 feet apart in a triangular form, one at the apex and the other three at the base of the triangle. The deeper the wells the greater the distance apart at which they were placed.

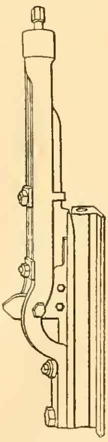

FIG. 3.—Perforator for slitting well pipes.

The up-stream well is charged with a strong electrolyte such as sal ammoniac, which passes down stream with the underground water to the lower wells (Fig. 1). Each of the down-stream wells contains within the well point an electrode consisting of a nickel brass rod ⅜-inch thick by 4 feet long, insulated from the casing by wooden spools. This electrode communicates with the surface by means of rubber-covered copper wire, and connects with a recording ammeter. As the electrolyte reaches one of the down-stream wells its appearance is at once recorded by the

[2] "Water Supply and Irrigation Papers," Nos. 99 to 132. (Washington: Government Printing Office, 1904–5.)

meter, the time occupied in passing from the upper to the lower well being thus found, and giving the rate of flow of the water.

Further details of observations of underground flow as carried out by this method are given in paper No. 112, by Homer Hamlin, with numerous illustrations of the apparatus used.

Stove-pipe Wells.—In the same report is a paper by Charles S. Slichter on the method of sinking stove-pipe wells. These consist of a riveted sheet steel starter from 15 feet to 25 feet long, made of two or three thicknesses of sheet steel with a forged steel shoe at the lower end. The rest of the casing consists of two thicknesses of sheet steel made into riveted lengths of 2 feet, one set of sections being made just so much smaller than the other as to permit them to telescope together. Each outside section overlaps the inside section 1 foot. This casing is sunk, length by length, by hydraulic jacks, which press on the upper sections by means of a suitable head. After the well has been sunk to the required depth, a cutting knife is lowered into the well and vertical slits are cut in the casing opposite such water-bearing strata as may have been met with; a well 500 feet deep may have 400 feet of screen if circumstances justify it. The perforator is handled with 3-inch pipe. By raising slowly on the line with hydraulic jacks, cuts are made from three-eighths to three-fourths of an inch wide, and from 6 to 12 inches long.

The well casings vary in diameter from 17 inches to 14 inches, and are sunk to depths from 500 feet to 1400 feet, the yield of water varying from 300,000 to 3,000,000 gallons in twenty-four hours. The cost of a 12-inch 500 feet well is about 140*l.* for labour and 100*l.* for materials, the drillers being paid 1*l.* and the labourers 10*s.* a day. The soil where these wells are in use consists of mountain débris, clay, gravel, sand, and boulder.

Pollution of Streams by Waste from Factories.—Paper No. 103 contains a review of the laws in operation in the different States of America for the prevention of pollution of inland waters. The broad legal principles under which anti-pollution statutes become operative are explained, and important Court decisions are quoted to show the authority upon which certain deductions in the report are founded.

In paper No. 133 the special stream pollution arising from the refuse water from the "straw board" factories is dealt with. In Indiana, Ohio, and Illinois there are several large factories engaged in making pasteboard from rye, wheat, and oat straw. For this process 40,000 gallons of water are required to wash 1 ton of straw, and 3200 lb. of straw and 560 lb. of lime are required to make 2000 lb. of board. In an ordinary factory 2,000,000 gallons of water are used daily, which carries with it 19 tons of straw waste and 10 tons of lime. This waste generally runs into a neighbouring stream, and is the cause of a serious amount of pollution. The report of the Government Commissioner for Fisheries states that the pollution of the streams in Indiana by the refuse from the strawboard mills, oil mills, and pulp mills is greater than from any other source. The refuse from these covers the spawning beds and prevents the eggs from hatching, while it penetrates the gills of the living fish and either kills or drives them away from the streams.

The remedy is by chemical precipitation of the waste products, but it is contended that the small profit on the manufacture of strawboard does not permit of the application of the process required.

Another source of water pollution dealt with in this report arises from the overflow from the oil wells in Indiana. Around the city of Marion there are no less than seventy-five oil wells in a few square miles of territory. Upwards of 300 surface and rock wells in this area are suffering contamination from this source. The strata in this district consists of sand and gravel for about 50 feet, then clay for about 80 feet, and below this limestone. The water supply of the town and neighbourhood is derived from water in the limestone, and there is a constant flow of underground water. Oil occurs near the top of the formation. Beneath the oil is salt water. In order to form a reservoir for the oil the limestone is entered some distance, and the most successful wells are those which are drilled deep enough to allow a large amount of oil to collect, so as to be above the upper level of the brine. These oil wells are generally 1000 feet deep, the oil rising to within 600 feet or 700 feet of the surface. When the well is bored it is "shot" with nitroglycerin, which breaks up the limestone and forms fissures and small cavities which act as reservoirs into which the oil flows. The surface effect of the shooting is the violent ejection of salt water and oil, often to the extent of thousands of gallons. The oil and salt water then sink into the soil where it is porous, and finally reach the surface zone of underground flow, where they partake of the general movement of the water toward the main line of underground drainage, and cause its pollution. The brine and oil pumped from these oil wells is discharged into a settling tank. The oil, owing to its lighter specific gravity, settles at the top and is drawn off, the brine being discharged into any neighbouring creek or stream, or is allowed to sink slowly into the ground, in either case becoming a serious source of pollution to the water supply of the neighbourhood.

Paper No. 121 relates to the pollution of Lake Champlain, by M. O. Leighton. The report was made in consequence of complaints made to the Government that the water of the lake has been rendered unfit for domestic consumption; that the usefulness of the lake for watering cattle has been destroyed; and that the refuse poured into it is destructive to fish life. The cause of pollution is due to the waste discharged into it from the pulp mills situated on its banks. The analysis of the water and other details are interesting to those who have to deal with the making of pulp and similar industries.

Paper No. 122 is entitled "Relation of the Law to Underground Waters," by D. W. Johnson, and contains an outline of the main features of the laws respecting underground waters with the object of giving to the owner of such waters some idea of his rights and obligations concerning them. Such legal decisions as serve to show the relation of the law to the problems which are essentially geological in character are referred to. Underground waters are defined and classified. Although this paper refers to United States practice, there is a great deal of information that would be of service to water engineers in this country. We shall refer more fully to this paper in a future number.

THE PERCY SLADEN EXPEDITION IN H.M.S. "SEALARK" TO THE INDIAN OCEAN.

I HAVE just received the following interesting communication from Mr. Stanley Gardiner. It was written from Port Victoria, Seychelles, under date October 28, and is the fourth report of his expedition which he has sent home. Mr. Gardiner is expected home early in the New Year. For his earlier reports, see NATURE, August 10, October 5, and November 9. A. SEDGWICK.

Cambridge, December 1.

During the ten days that the *Sealark* left us at Coetivy while she was coaling in the Seychelles, we as thoroughly as possible collected the animals and plants of both the land and reef. The island was higher than any we had up to that time visited, having wind-blown sand ridges and hills up to 80 feet above sea-level, arising on a flat coral reef. Although situated only about 130 miles to the south of the Seychelles Islands, the land fauna and flora are almost the same as on the islands of the Chagos Archipelago, being scarcely richer in either. The plants, of course, in the main necessarily govern the fauna, and it would appear to us that they are in their turn governed rather by the nature of the soil—coral and coral sand—than by their proximity to continental land. On the other hand, the reefs of Coetivy showed in every group of marine animals a more varied fauna than those of the Chagos, while very nearly all the species of the latter seemed to be present. The reef on the eastern, or seaward, face of the island was of a rather different character from any we had as yet seen (or from any I have seen in the Pacific), being covered with a grass-like weed, locally termed "varech." There was also on the same part a

considerable variety of other algæ, but the edge and outer slope were, as elsewhere, covered by corals and nullipores. The reef, however, to the west, where there is a flat extending out for some miles with about 16 fathoms of water, closely resembled similarly situated reefs in the Chagos, but the greater variety of its organisms was equally marked, though individual species were much less common.

Leaving Coetivy on September 25, we proceeded to a point about midway between Madagascar and Farquhar Atoll, both to ascertain the depth and the compass variation. The latter was almost the same as at Mauritius, situated 9 degrees to the south, while the depth, 1856 fathoms, precludes the idea of any close connection between the two localities. Farquhar, which we then visited, was (as, indeed, were all the reefs we subsequently saw) remarkable for its almost completely covered "varech" reefs, both rim and lagoon. Its land attains a height of more than 70 feet, and is clearly of the same formation as that of Coetivy; it shows no trace of elevation, and it has not been formed, as has been stated, by submarine deposits. The section of the reef also showed the outer slope to be quite similar to that of other atolls.

From Farquhar we proceeded to sound between the chain of islands that extends between Madagascar and the Seychelles, and which would appear to indicate a line of former connection. Between Farquhar and Providence, 32 miles, we found 890 fathoms, and between the latter and Alphonse-François, 155 miles, 2170 fathoms, while there were already soundings of 952 fathoms between Alphonse and the Amirante Group, 46 miles, and of 1150 fathoms between the latter and the Seychelles, 32 miles. As the depth on either side is only about 2300 fathoms, any connecting ridge is comparatively low and of doubtful importance.

Providence was particularly interesting, being simply a great reef, 28 miles long by 7 miles broad to the 100-fathom lines. Off it we took twelve dredgings, obtaining a rich fauna down to about 100 fathoms, below which the bottom was exceedingly barren of life. From one dredging at 744 fathoms, 3 miles to the west of the reef, we obtained about 5 cwt. of stones, the largest about 2 feet in diameter. We have here no means of properly ascertaining their nature, but similar rock has not, so far as we are aware, been hitherto described off any coral reef. It is almost entirely insoluble in acids, and is largely formed of different crystals, organic deposits practically not entering into its composition. Some masses looked like solidified ash or clay, while others *appeared* rather like volcanic bombs. All were more or less coated with manganese, but we do not know its thickness, preferring to keep the specimens intact for proper examination on our return to England. However, it is clear that the existence of this rock in such a position will have to be carefully considered in connection both with the formation of Providence Reef and with the existence of any former land connection between the Seychelles plateau and Madagascar.

Pierre Island, 17 miles to the west of Providence Reef, and with a depth of 1088 fathoms between, is peculiar in having no fringing reef. It is simply an elevated coral island, reaching to a height at present of about 30 feet, surrounded by overhanging cliffs, so that landing is extremely difficult. Its rock is entirely coral.

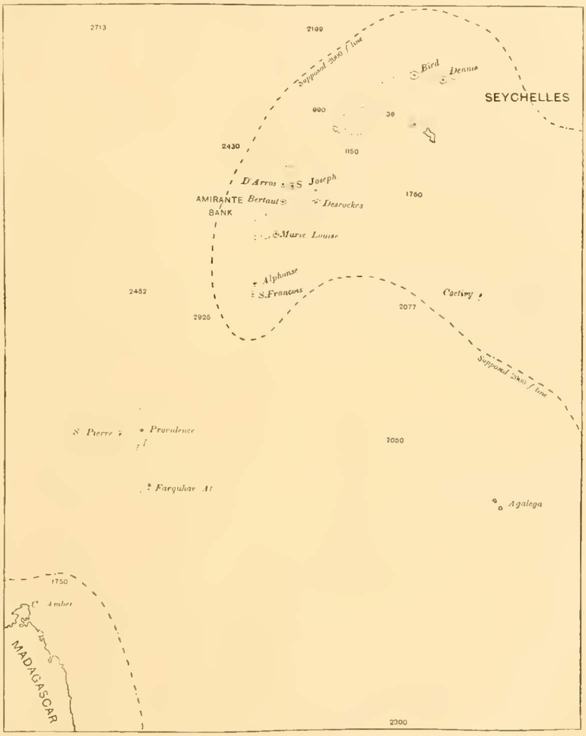

Fig. 1.—Chart of the Indian Ocean between Madagascar and the Seychelles.

Alphonse and François are sandbanks on the rims of two reefs, scarcely 2 miles apart. Both reefs are of atoll formation, the lagoon of Alphonse (not shown in any chart) being 3 to 8 fathoms deep and of considerable size.

The Amirante Islands are likewise sandbanks, no parts of any being more than 10 feet above the high-tide level. The hills represented in the separate enlarged plans of D'Arros, St. Joseph, and Desroches do not exist, and probably owe their presence thereon to the imagination of the draughtsman.[1] Desroches is really an atoll by itself, lying 10 miles to the east, and being separated by a channel 874 fathoms deep. The rest of the islands and reefs lie on a bank about 50 miles long by 20 miles broad, with an average depth of about 30 fathoms. Eleven separate reefs reach the surface, of which St. Joseph alone has a lagoon, being really a small atoll with about 4 fathoms of water in the centre. With the exception of Eagle, D'Arros, and Bertant, all the reefs lie on the edge of the bank, but its edge is in most places covered by at least 8 to 10 fathoms of water. Its slope is steeper than is customary off coral reefs, no possible dredging ground existing between 60 and 500 fathoms.

All the islands of the Amirante Group, with the exception of Marie-Louise and Eagle, are now planted for cocoanut oil, but the indigenous vegetation still remains in places. The land plants and animals are almost the same as at Coetivy and in the Chagos, the additions due to the

[1] If we had had any idea of this earlier, we should have probably visited Cosmoledo and perhaps Aldabra.

proximity of Africa and the Seychelles being relatively few. The marine fauna and flora was markedly richer than even at Coetivy.

Of other work, we have taken about sixty dredgings off the islands we visited down to more than 800 fathoms, and tow-nettings at various depths to more than 1000 fathoms. We have consequently rich collections, but obviously no estimate of them can be at present formed. We have also serial temperatures in a series of positions, and water samples have been taken throughout down to various depths. Magnetic observations have also been secured at intervals along the line between Madagascar and the Seychelles.

As we are now leaving H.M.S. *Sealark*, I would like to express our great indebtedness to Commander Boyle T. Somerville and every officer and man on board for their great kindness and most cheerfully rendered assistance to Mr. Forster Cooper and myself. Nothing has seemed too great or intricate or small for them to undertake, from a complicated survey to the repair of delicate instruments or dredges. The weather throughout the voyage—the season chosen was governed by considerations relating to hurricanes—has been, generally speaking, most unsuitable and unpleasant, but work has nevertheless gone on almost continuously. All regular survey work, sections across the islands, soundings, magnetic, tidal and temperature observations, &c., have been done by Commander Somerville and his officers. Mr. Beer, the artificer engineer in charge, and his staff have been indefatigable in eking out the coal, on which our movements necessarily depended to a large degree, and in effecting the not inconsiderable repairs connected with such a long cruise away from regular ports. The artificers (carpenter, blacksmith, and armourer) have never failed over the varied and unusual work which they have at times been called upon to undertake, and, finally, every individual hand has been splendid in giving of his very best to assist the expedition to success.

J. STANLEY GARDINER.

FORESTRY IN BELGIUM.

THE Royal English Arboricultural Society paid a visit to the Belgian forests on August 12–22. The Belgians, like ourselves and all other European countries, except Scandinavia, Russia, Austria, and some of the smaller States near the Black Sea, have insufficient woodlands to supply the timber that is necessary for their requirements. In 1840, Belgium imported 187,920*l.* worth of timber, but in 1893 the imports were valued at 4,677,880*l.*, together with about 1,200,000*l.* of wood-pulp and other articles manufactured out of wood, such as matches, gun-stocks, masts, furniture, bark, &c. The annual exports of wood from Belgium are now valued at 600,000*l.* only, so that there is an annual deficit of timber production in the country amounting to more than 5,000,000*l.*

The Belgian Government is dealing with this deficit in the most statesmanlike manner, by using all available means for increasing the production of timber, by improving the management of the existing woodlands, and by planting their waste-lands.

The areas of woodlands in Belgium, according to the agricultural statistics of 1895, are as follows:—

Nature of proprietor	Area in acres
State	62,600
Communes	395,455
Public establishments	17,380
Private owners	828,300
Total	1,303,735

The area of forests in Belgium is therefore about one-sixth of the total area of the country.

The small area of the Belgian State forests is chiefly due to the fact that, between 1815 and 1830, when the country was united to Holland, the Government sold all the State forests, and the present area of State forests has been bought back from private owners through the wise policy of the first king, Leopold I.; this has been continued recently by the present Government, which purchases suitable private woodlands whenever they are for sale.

In 1850 there were the following areas of waste-land in Belgium; I have not been able to obtain more recent figures:—

	Acres
State	17,140
Communal	145,267
Private	423,322
Total	585,729

Since 1897 the State has been acquiring waste-lands and re-planting them, 212,960*l.* having been so invested up to date, and land to the extent of 15,317 acres having been acquired and planted.

The State has no power of compelling communes to plant their waste-lands, but important subsidies are granted by the State to encourage them to do so. The Forest Department also organises annual sylvicultural conferences with the object of inducing communes and private owners to utilise their waste lands. This has been so successfully managed, that in the province of Luxemburg, where there were in 1847 126,000 acres of waste-land, by the end of 1887 only 42,000 acres of waste remained in the province, the balance having been converted into 49,000 acres of arable land and pastures and 35,000 acres of woods.

In the space of this short article it is impossible to do more than give a mere sketch of the interesting woodlands recently visited by the Royal English Arboricultural Society in Belgium. It would interest British municipalities, such as those of Liverpool and Leeds, that are engaged in planting the catchment areas of their waterworks, to see the immense tract of woods that cover the catchment area of the Gileppe, a stream rising in the Ardennes and feeding a large reservoir, constructed between 1869 and 1898, to supply water for the population that carries on the extensive woollen industry in Verviers and the other hamlets lower down. The planting with spruce of the Hautes Faynes, or peat district of the Hertogenwald, at altitudes between 1600 and 2160 feet, which is being carried on at the rate of 1000 acres annually, is a vast and highly original work, the rapidity and excellence of which merit careful study.

Plantations of Austrian pine on the very dry and hot Devonian limestone rocks, near Rochefort, supply valuable wood as pit-timber, and afford shelter and increased moisture to the neighbouring farms. The domain of Mirwart, belonging to an Antwerp family named von der Becke, and managed by Dr. Schlich, where millions of spruce and other trees have been planted to replace 32,000*l.* worth of inferior timber that was cut out between 1892–1902, was also visited. Here, forty acres of Scots pine, now thirty years old, has already yielded in thinnings, since 1891, 11*l.* per acre net, while in another eight years, when the whole will be felled as pit-timber, it will yield 64*l.* per acre, or a total return, including thinnings, of 75*l.* per acre.

The domain of Chenoy, belonging to Mr. Boël, contains magnificent beech, oak, and ash standards over coppice. The underwood is sold as pit-timber. Oak trees containing 100 to 140 cubic feet (solid measure) are not uncommon, and some of the ash standards are quite as large. These trees sell standing at 2*s.* and 2*s.* 6*d.* per cubic foot. Abeles (*Populus alba*) up to 80 feet in height are not uncommon, and sell at 9*d.* per cubic foot. It is a curious feature of these woods that whenever the aspect is south or west, the poor Tertiary sandy soil (Bruxillien), from which the fertile superficial loam has been washed, will yield only pines or birch, while immediately the aspect changes to north or east, and the loam remains *in situ* over the sand, splendid broad-leaved woods are produced. In the valleys, Silurian rock crops out from below the sand, all the usual intermediate strata being absent. There we saw a considerable area of Scots pine wood, about forty years old, the trees of which are being pulled up by their roots by a machine, "La

déracineuse Lobo." This operation costs 4*d*. per tree uprooted; but the poles are thus a foot longer than those that are simply felled, and the roots are used for fuel, while the land can be at once planted, without waiting three years from fear of the pine-weevil (*Hylobius abietis*), which otherwise breeds in the stumps, and then destroys the young crop planted to replace the felled trees.

The last forest visited by the society was the Forêt de Soignes, one of the most magnificent beech forests in Europe. The oldest crops consist of columnar beeches 130 years old, 130 to 140 feet high, averaging $4\frac{1}{3}$ feet in girth at chest height, and containing per acre 7000 cubic feet (quarter-girth measure). This forest of 10,210 acres yields a net annual revenue of 18,000*l*. for timber alone; the game, chiefly roebuck, rabbits, and pheasants, is fully worth 4*s*. an acre, but is retained for the King.

The geographical arboretum at Tervueren merits special attention. Here, 75 acres of good undulating loamy land, with a crop of small oak and other saplings, which serve as a shelter-wood, are being planted with exotic trees. The whole area is subdivided into the Old and New Worlds, and each of these into smaller sections, representing countries running from north to south. Thus the "New World" is first subdivided into the Pacific and Atlantic regions, and the former into Alaska, Rocky Mountains, Pacific coast region, and Chile. The Atlantic region into Canada and the Alleghany Mountains. The Old World comprises Northern, Central, and Eastern Europe, Siberia, Caucasus, the Himalayas, Japan, and N. China.

In each of these regions the characteristic trees, broad-leaved and conifers, are planted in their natural mixture. It is also intended to plant among them the shrubs and herbaceous plants that naturally grow with the trees, and this has already been done for Japan. Mr. Bommer, the curator of the Botanic Museum at Brussels, is in charge of this arboretum. He has an extensive forest nursery where he rears the necessary plants. This bold and scientific design is due to the initiative of the King of the Belgians, who has presented the State with the splendid domain of Trevueren, the management of which he still controls.

The Director-General of Forests, Mr. Dubois, has certainly organised the administration of the Belgian forests in a remarkably progressive way, and the system he has adopted in Belgium is probably more suited than those of France and Germany for the future development of forestry in Britain. W. R. FISHER.

THE CAPE GEOLOGICAL SURVEY.[1]

THE presentation of the ninth annual report of the Geological Commission of the Cape of Good Hope will be welcomed by all interested in the prosperity of one of our oldest colonies in Africa. We have been so long accustomed to see similar surveys started and then abandoned before sufficient information had been obtained to yield permanent results that we were afraid that the publication of this report might possibly have been postponed. The past record of surveys of Cape Colony has, indeed, been a dismal one, so hampered have they been in their prosecution, so undervalued have been the results. Fortunately, necessity knows no law, and there are few portions of Africa which do not possess a more or less fully equipped geological survey.

A considerable amount of new and useful knowledge was obtained in Cape Colony during 1904, though the results are not so complete as they doubtless would have been if lack of funds had not prevented the continuation of the survey in important areas, but where the cost of hired transport was found to exceed the limit of the grant voted for the survey.

In the introduction by the director the main results obtained during the past year are recorded, but all too briefly. How little is known of the different rock groups even in these southern and best known regions of Cape Colony is shown by the discovery of a new set of rocks, termed Nieuwervst series, which are found to be newer than the Ibiquas and Malmesbury series, but older than the Table Mountain Sandstone. The succession in southern Cape Colony, the type region for South Africa, is thus being brought into closer approximation with that of northern Cape Colony and the Transvaal, with a result that cannot fail to be beneficial to both. Further, a closer parallelism is found to exist between the geological history of South Africa and the southern continents than zoologists and geologists dared to hope, but on which each alike confidently felt would be the case.

In the detailed account Mr. Rogers describes the geology of the north-western part of Van Rhyns Dorp. Among the Malmesbury beds a characteristic feature consists of the abundance of crystalline limestones intercalated between slates and phyllites. The account of the intrusive granites and the metamorphic rocks with the associated sillimanite-cordierite schists contains much of interest. The Ibiquas series and the unconformably overlying Nieuwervst series deserve close attention, owing to the light they will probably throw on the Transvaal succession.

In the district of Long Kloof Mr. Schwarz finds the geology to be highly complicated by folding. A somewhat fanciful explanation is offered to account for the elevation of the mountains in this area being no greater than in the less folded regions composed of the same rocks.

In the description of the geology of Aliwal North, Herschel, Barkly East, and part of Wodehouse, Mr. du Toit enters into much detail concerning the stratigraphy and composition of the Upper Karroo beds and the volcanic phenomena associated with them. A great addition to our knowledge of the sedimentary and volcanic beds of the Stormberg series will here be found. By means of the special reptilian contents in the upper portion of sandstones, red and purple shales, mudstones and clays, it has been found possible to subdivide the great thickness of the Beaufort series. For this superior group the term Burgersdorp beds is proposed. Besides their abundant reptilian contents, they are further interesting from the occurrence of Lepidodendron in association with Glossopteris and Thinnfeldia.

In the succeeding Stormberg period chief interest is centred in the careful description of the volcanic outbursts, more especially of that of the volcanic necks. Of these, thirteen are recorded from Wodehouse, twenty from Barkly East, and twenty-two from Herschel, those in Aliwal North being left for further investigation. The description includes most reasonable hypotheses for the formation of the different types of rock infilling the necks. The immense flows of lava and numerous dolerite intrusions receive due attention, the intrusion of the dolerites being placed somewhere between the Middle Jurassic and Lower Cretaceous.

Questions of economic importance will be found to have been thoughtfully considered. It is disappointing to find that so far the coal seams met with in Aliwal North and Herschel are thin and of less value than in the south.

The introduction throughout the report of black and white geological maps of the areas surveyed with a sufficient number of place-names enables the reader to follow the various descriptions with ease. The absence of headlines, and the want of a copious table of contents, constitutes a drawback to the general reader, particularly where the report deals with petrological descriptions.

Those persons who consider that the work of a national survey should be primarily devoted to the economic aspect of the inquiry will doubtless be disappointed at the apparent poverty of the commercial results obtained by the Survey since the date of its commencement in 1896. The explanation is obvious. A national survey cannot be formed for a particular section of the community interested in the discovery of gold, coal, or diamond fields. It is, however, expected of such a survey, and that of the Cape fully realises the expectation, that the maps and memoirs it publishes should represent the most trustworthy and technical information it is possible to obtain as to the geological structure of the country it professes to examine, and on which the practical man who follows must and does base his conclusions. W. GIBSON.

[1] Ninth Annual Report of the Geological Commission of the Cape of Good Hope. Pp. 181. 1904. (Cape Town, 1905.)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The list of the scholarships awarded at the twelve larger colleges was issued last Saturday. Excluding exhibitions, sizarships, and subsizarships, the amounts of which are uncertain and the number in many cases undetermined, the amount given away in the twelve colleges amounts to 5430*l*. The seven colleges, Pembroke, Caius, King's, Jesus, Christ's, St. John's, and Emmanuel, gave away sixty scholarships of a total value of 3380*l*.; whilst the Trinity group, consisting of Trinity, Clare, Trinity Hall, Peterhouse, and Sidney, gave away 2500*l*. for thirty-seven scholarships.

The total amount in the former group given for classics is 1560*l*., for mathematics 1000*l*., and for natural sciences 620*l*., the number of scholarships being:—in classics twenty-six, in mathematics seventeen, and in science twelve. The proportion of science to the other subjects is better in the group of five colleges, for their science scholarships numbered ten of a value of 560*l*., as opposed to sixteen scholarships in classics the total value of which amounted to 880*l*. We have left out of account the comparatively small sum of 340*l*. which was given for history, Hebrew, and modern languages.

DR. H. A. WILSON, senior lecturer in physics at King's College, London, has been appointed professor of physics at the college in succession to Prof. W. G. Adams, who resigned last July.

REUTER'S correspondent at Tokio reports that the resignation of the Japanese Minister of Education has been accepted, and the differences between the university and the Government have thus apparently been settled. Count Katsura, the Premier, has taken the portfolio of education, while retaining the Premiership. The resignations tendered by the professors have not been accepted.

IN a paper read at the American Mining Congress at El Paso, Texas, on November 14, Mr. V. C. Alderson, president of the Colorado School of Mines, urged mining schools to go beyond mere instruction and to enter the field of research. There was not at present, to his knowledge, a mining school in the United States which had a department of research in good working order. There should, he considered, be such a department at a State mining school to work in conjunction with the State Bureau of Mines.

MR. E. ROBINSON, of Boncath, opened a discussion on the question of the establishment of a school of forestry for Wales at the annual meeting of the agricultural society of the university college at Aberystwyth. He said that, if the seven Welsh counties affiliated to the college would vote on an average 30*l*. each and give an annual subsidy of 100*l*. each for eight years, the proposed school of forestry after that period could easily be made self-supporting. The Government, he urged, must come forward to second the efforts of the county councils by advancing money to landowners at a reasonable rate of interest. Mr. J. Herbert Lewis, M.P., said that the question of afforestation is rapidly becoming one of national concern. A departmental committee has made it clear that a shortage in the world's supply of timber may be looked for in the near future, and that millions of acres of waste land in the United Kingdom are suitable for afforesting. Our large municipalities could do much, following the example of the Liverpool Corporation at Vyrnwy, by afforesting the catchment areas of their waterworks.

SCARCELY a week passes without the announcement of substantial gifts to one or other of the universities of the United States. In addition to those mentioned in NATURE of last week, *Science* announces the following donations:—Mrs. Phoebe Hearst has presented to the California State University her archæological and anthropological collection from all parts of the world. It has cost more than 80,000*l*., and with it she presents to the university 12,000*l*. for the maintenance of a department of anthropology. Hope College, Holland, Mich., recently received 20,000*l*. from Mr. Ralph Vorhees, of Clinton, N.J. A new chemistry hall has been erected for the university of North Carolina by a legislative appropriation of 10,000*l*. Mrs. Clara C. Jacobus has given 5000*l*. to found a fellowship at Princeton University, to be conferred on the graduate student who has reached the highest excellence in his work during the previous year. An anonymous donor has given 2000*l*. to establish a fellowship in chemistry. Mr. Henry B. Loomis has given 2000*l*. to the scientific school of Yale University to establish a fellowship in chemistry.

THE council of the Association of Technical Institutions has issued a report of an inquiry as to the cooperation of employers and technical institutions. A form of inquiry was sent to each of the sixty-five institutions affiliated to the association, to technical institutions and university colleges not thus affiliated, and to some of the large employers of labour whose educational work with their employees was not likely to be connected with the various technical institutions already approached. The answers received to the questions asked on the form of inquiry are analysed under several headings, among which may be mentioned the trades to which the scheme of cooperation applies, the number of students affected by the scheme, the payment of class fees, the provision of books, and leave of absence to attend classes. The report, in its summary of the results of the inquiry, states that if regarded from the point of view of how few of the army of masters appear to interest themselves at all in the technical education of their workers, the record cannot be other than disappointing, especially in view of the different attitude of employers on the Continent and in the United States. On the other hand, if looked at in comparison with the attitude of employers ten years ago, the result is most hopeful. It is interesting in this connection to note that in distributing prizes to the students of the Gateshead higher evening classes, Sir Isambard Owen suggested that it would pay employers to enable their apprentices to work shorter hours by day on condition that they availed themselves of the opportunities for evening instruction. Continuing, he said the great desire of the Plumbers' Company is now to adopt measures for advancing the apprenticeship system, in view of the indisposition of employers, who are keenly competing with each other to obtain plumbing work at a profit, to burden themselves with apprentices, thus ignoring the importance of training the coming generation of plumbers. This pressure of commercial interests over the craftsman spirit constitutes a serious menace to efficiency, not only in the plumbing trade, but in other skilled industries.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 16.—"The Physical and Chemical Properties of Iron Carbonyl." By Sir James **Dewar** and H. O. **Jones.**

The paper contains an account of a study of the properties of iron pentacarbonyl, which has been carried out on the same lines as the previously published investigation on nickel carbonyl. Attention has been directed more particularly to the differences between the iron and nickel carbonyls, such as the difference in formulæ $Fe(CO)_5$ and $Ni(CO)_4$, colour (the iron compound is yellow and the nickel compound is colourless, whereas the salts of the latter metal usually show a much more marked colour than those of the former), and stability, and to the action of light on iron carbonyl.

Pure iron carbonyl is a yellow liquid, which boils at 102°·5 C. and freezes at −20° C. to a yellow solid, which becomes colourless at −180° C. Analysis, vapour density determinations, and molecular weight determinations by the cryoscopic method in benzene show that its formula is $Fe(CO)_5$.

The specific gravity of the compound is 1·4937 at 0° C. and 1·3825 at 60° C.; its critical temperature is 288° C.

The formula $v=1{\cdot}974-0{\cdot}5307\,(\log 288-t)$ expresses the relation between the volume of the liquid v and the temperature t° C.

The relation between the vapour pressure p in millimetres of mercury and the absolute temperature T is expressed by the Rankine formula $\log p=7{\cdot}349-1681/T$.

The critical pressure is calculated to be 29·6 atmospheres, and the critical density 0·49.

The value $\frac{\text{abs. critical temperature}}{\text{critical pressure}}$ is 18·9; this is proportional to the volume of the molecule, and is equal to 5·1 times the corresponding number for carbon monoxide (3·7). The molecular volume of iron carbonyl at its boiling point is 150, so that, taking 7·0 as the volume of the iron atom, 28·6 is the volume of each carbon monoxide group. The molecular volume of carbon monoxide at its boiling point is 35, therefore a greater contraction would occur in the formation of iron carbonyl from liquid carbon monoxide and iron than in the formation of nickel carbonyl under similar conditions.

Vapour density determinations by V. Meyer's method in carbon monoxide, nitrogen, and hydrogen at different temperatures show the effect of increase of temperature and the rapid diffusion of hydrogen in increasing, and of carbon monoxide in diminishing, the dissociation.

The chemical reactions of iron carbonyl are very similar to those of nickel carbonyl, but its stability is greater. Chlorine, bromine, iodine, their compounds with one another and their hydrides react with iron carbonyl giving *ferrous* salts and carbon monoxide; the reaction with bromine takes place more slowly than that between iodine and nickel carbonyl. Neither sulphur nor nitric oxide reacts with iron carbonyl, whereas both react readily with nickel carbonyl. Sulphuric acid, on the other hand, decomposes iron carbonyl more readily than it does nickel carbonyl.

Benzene in presence of aluminium chloride reacts with iron carbonyl, with cold to give benzaldehyde, and at 100° C. to give anthracene, exactly as with nickel carbonyl.

Iron pentacarbonyl alone or in solution in ordinary organic solvents is decomposed by sunlight according to the following equation, $2Fe(CO)_5 = Fe_2(CO)_9 + CO$. The second compound of iron and carbon monoxide is deposited as an orange, crystalline solid from most solvents, but is retained in solution by pyridine. The reaction takes place rapidly under pressures of carbon monoxide up to 150 atmospheres, and yet is very slowly reversed in the dark under small pressures of carbon monoxide. This decomposition takes place slowly at the temperature of liquid air, but if the iron pentacarbonyl or its solutions be heated to any temperature above 60° C., then no solid is deposited and no decomposition occurs. Solutions of iron carbonyl in nickel carbonyl at the ordinary temperature undergo no decomposition and no solid is formed unless the solution contains more than 30 per cent. of the iron carbonyl, when some solid is formed. These solutions are of a much lighter colour than solutions of equal concentration in other solvents, and it is suggested that the two carbonyls may unite to form a compound which is unaffected by light.

The solid iron carbonyl forms lustrous hexagonal plates having a specific gravity of 2·085; its molecular volume is therefore 174.

The solid iron carbonyl when heated alone decomposes at 100° C. into carbon monoxide, liquid iron carbonyl, which is coloured green, and iron; when heated with carbon monoxide under pressure it is completely converted into liquid iron pentacarbonyl.

If the solid iron carbonyl be heated with a solvent such as ether or toluene, a solution of an intense green colour is produced; this green solution on exposure to light deposits the yellow, crystalline, solid carbonyl again. The change from solid to green solution and back again can be repeated indefinitely by the action of heat and light alternately.

Zoological Society, November 28.—Dr. Henry Woodward, F.R.S., vice-president, in the chair.—*Exhibitions.*—Photographs of a horse bearing incipient horns: J. T. **Cunningham.** The horns were about ¾-inch in length, the left being slightly larger than the right, and there could be no doubt that they were outgrowths of the frontal bone. The growths were covered with normal skin and hair.—Photographs, taken in the Horniman Museum at Forest Hill, of a sea-anemone (*Anemonia sulcata*) in the process of division: F. **Slade.**—A living albino specimen of the field-vole (*Microtus agrestis*) captured last July in Wales: D. **English.**—A living lizard, *Lacerta muralis*, from Brozzi, province Florence, received from Dr. A. Banchi: G. A. **Boulenger,** F.R.S. The lizard belonged to the typical form of the wall-lizard, but was remarkable for its black coloration above and below. Melanistic forms of the wall-lizard were well known on small islands in the Mediterranean, but, so far as Mr. Boulenger was aware, no black specimen had ever been recorded from the mainland. The scales across the body numbered fifty-eight, and the lamellar scales under the fourth toe twenty-five in the specimen exhibited, these two numbers being sufficient to distinguish the Brozzi lizard from the melanotic insulars previously described.—A living specimen of the violet-cheeked humming-bird (*Petasophora iolota*) brought from Venezuela and presented to the society's menagerie: Captain A. **Pam.** A general account of the habits of these birds, as observed by Captain Pam, in a wild and captive state, and notes on their management and feeding while in confinement.—A named set of the birds collected in Japan by Mr. M. P. Anderson in connection with the Duke of Bedford's exploration in eastern Asia: W. R. **Ogilvie-Grant.** No new species were obtained, but several of the specimens were of special interest as illustrating stages of plumage not represented in the British Museum.—*Papers.*—A transition in the general type of colouring from the wholly black *Colobus guereza* in one direction, through several intermediate forms, towards the black and white *C. caudatus*, and in another direction towards *C. vellerosus*: R. **Lydekker.**—A mounted specimen of the white-maned serow (*Nemorhaedus argyrochaetes*, Heude), of Szechuen, the first example of the species ever received in England, and perhaps in Europe: R. **Lydekker.**—Mammals collected in Japan by Mr. M. P. Anderson for the Duke of Bedford, and presented by the latter to the National Museum: O. **Thomas.** The collection was one of the most valuable for scientific purposes which had ever been received from any one region. More than 600 specimens had been obtained, belonging to 50 species and subspecies, of which several were described as new.—A revision of the fishes of the family Galaxiidæ: C. T. **Regan.** Two genera were recognised, Galaxias and Neochanna, the latter consisting of a single species only. Twenty-eight species of Galaxias were described, including *G. attenuatus*, Jenyns, found on the coasts and in the rivers of Australia, New Zealand and Chili, Patagonia, and the Falkland Islands, and two peculiar to the Cape of Good Hope, five to New Zealand and the neighbouring islands, five to Chili, Patagonia, and the Falkland Islands, and fifteen to Australia and Tasmania. Five species were described as new to science.—The mammalian fauna of China. First paper: J. L. **Bonhote.** The present part dealt with the Murinæ, containing the genera Mus and Micromys, giving descriptions and synonymy, as well as emphasising the distinctive characters by which the various species might be easily distinguished.—Some additions to the knowledge of the anatomy, principally of the vascular system, of Hatteria, Crocodilus, and certain Lacertilia: F. E. **Beddard.**—Descriptions of 111 new species of phytophagous Coleoptera of the family Halticidæ: M. **Jacoby.**

Chemical Society, December 7.—Prof. R. Meldola, F.R.S., president, in the chair.—The constitution of nitrites, part i., two varieties of silver nitrite: P. C. **Rây** and A. C. **Gañguli.** The α variety of silver nitrite is prepared by double decomposition between solutions of silver nitrate and sodium nitrite. The β variety is obtained by dissolving the α variety in boiling water, and from the hot saturated solution the nitrite is allowed to crystallise. The two forms show differences in crystalline structure and mode of decomposition by heat.—The products of heating silver nitrite: E. **Divers.** The author, while accepting Rây and Gañguli's experimental data, dissents from the view that these are two forms of silver nitrite.—A contribution to the chemistry of benzoic sulphinide: F. D. **Chattaway.** When chlorine is passed into a solution of the sodium salt of saccharin, *o*-benzoic N-chlorosulphinide or chloroiminosaccharin is precipitated. An account of the properties of this substance is given.—The action of heat on α-hydroxycarboxylic acids, part ii., α-hydroxymargaric acid, α-hydroxypalmitic acid, α-hydroxy-

pentadecylic acid, and α-hydroxymyristic acid: H. R. **Le Sueur.** The aldehydes obtained by the pyrogenetic decomposition of these acids are white solids, readily soluble in the ordinary organic solvents; they form oximes, semicarbazones, hydroxycyanides, and are oxidised to the corresponding acids.—Studies on optically active carbimides, part ii., the reactions between *l*-menthylcarbimide and alcohols: R. H. **Pickard,** W. O. **Littlebury,** and A. **Neville.** *l*-Menthylcarbimide reacts readily with alcohols, and fourteen of the latter have been shown to yield *l*-menthylcarbamates. These reactions have been studied polarimetrically, and the velocity constants of reaction so obtained compared.—The liberation of tyrosine during tryptic proteolysis. A preliminary communication: A. J. **Brown** and E. T. **Millar.** The authors have applied Millar's method of estimating tyrosine by means of bromination to the study of the tryptic hydrolysis of proteids, and find that tyrosine is one of the first products of such action. The quantitative study of proteolysis in this way may throw some light on the existence or non-existence of a tyrosine nucleus in different albuminoses.—Ethyl piperonylacetate: W. H. **Perkin,** jun., and R. **Robinson.** A description of the preparation of this ester from piperonylic acid.—The action of ultra-violet light on moist and dried mixtures of carbon monoxide and oxygen: S. **Chadwick,** J. E. **Ramsbottom,** and D. L. **Chapman.** It was found that under the action of the rays emitted from a quartz mercury lamp a dry mixture of these gases was largely, but somewhat irregularly, converted into carbon dioxide and ozone. With *moist* gases the rate of conversion was slower and more uniform, and more carbon dioxide was formed and less ozone.—Benzoyl derivatives of salicylamide: A. W. **Titherley.**—The constitution and colour of diazo- and azo-compounds: A. **Hantzsch.** A criticism of Armstrong and Robertson's paper, "The Significance of Optical Properties as Connoting Structure" (*Journ. Chem. Soc.*, 1905, 1272–1297).—Note on the incandescent mantle as a catalyst and its application to gas analysis: J. E. **Mason** and J. **Wilson.** The authors describe a modification of Lewes's method (*Chem. News*, 1905, xci., 61) for showing the incandescence of the mantle in an unburnt mixture of alcohol vapour and air. Although less effective, the mantle may be used as a substitute for platinised asbestos in the ordinary lecture experiments for preparing formaldehyde from methyl alcohol vapour and air, and sulphur trioxide from sulphur dioxide and oxygen, and various applications of mantle fragments to the analysis of mixtures of hydrocarbon gases by combustion are given.—The influence of certain amphoteric electrolytes on amylolytic action: J. S. **Ford** and J. M. **Guthrie.** The results of an investigation of the influence of various amino acids on amylolytic action are given.—The estimation of picric acid additive compounds: F. S. **Sinnatt.** The method of Knecht and Hibbert (*Ber.*, 1903, xxxvi., 1549) for the estimation of picric acid by means of titanous chloride has been found to be applicable to picrates and to picric acid additive compounds.—Silver dioxide and silver peroxynitrate: E. R. **Watson.** The author has analysed the anodic product formed during the electrolysis of solutions of silver nitrate, and finds that its composition was correctly represented by Sûlc's empirical formula $Ag_7O_{11}N$. This compound on boiling with water decomposes, forming silver dioxide, a greyish-black powder which may be heated to 100° without decomposition.—The constitution of *o*-hydroxyazo-compounds. Preparation of benzeneazodimethylcoumarin: J. T. **Hewitt** and H. V. **Mitchell.** Caro's permonosulphuric acid: T. S. **Price.** The author has obtained a mixture containing the potassium salts of sulphuric, permonosulphuric, and perdisulphuric acids. The results obtained by the analysis of this mixture point to the formula H_2SO_5 for Caro's acid.

Royal Astronomical Society, December 8.—Mr. W. H. Maw, president, in the chair.—Account of the results of his recent investigations relating to sun-spot periods: Prof. A. **Schuster.** Besides the recognised 11- or $11\frac{1}{4}$-year period, the author found various subsidiary periods which recur with great regularity, but which sometimes disappear. A period of about $4\frac{3}{4}$ years could be traced back to 1749, and other periods of about $8\frac{1}{2}$ and 13 years were also indicated. Possible explanations of the peculiarities of these periods were suggested.—On the astronomical observations recorded in the Nihongi, the ancient chronicle of Japan: E. B. **Knobel.** The astronomical observations contained in this work comprise eclipses of sun and moon, occultations, conjunctions, comets, meteors, &c., and range from A.D. 620 to A.D. 696. There is great difficulty in fixing the dates of the observations owing to the complicated system of chronology, borrowed from China. The year is a lunar one of twelve months of twenty-nine or thirty days, and an intercalary month every thirty-third month, or seven intercalary months in the lunar cycle of nineteen years. The rules for intercalary months are very complicated, and there is therefore much difficulty in reducing the dates to European chronology. Most of the recorded eclipses agree with Oppolzer's tables when the dates are properly reduced.—On the present state of lunar nomenclature: S. A. **Saunder.** The paper showed the anomalies and irregularities in the present system, resulting in difficulculties of identification in the case of many of the smaller features on the moon which had been selected as points for exact measurement. It was suggested that a committee should be formed to revise the present system of lunar nomenclature.—Photographs of comet *d* 1905 taken with the 30-inch reflector of the Royal Observatory, Greenwich, shown by Prof. F. W. **Dyson.**—Comparison of the results from the Falmouth declination and horizontal force magnetographs on quiet days in years of sun-spot maximum and minimum: Dr. C. **Chree,** F.R.S.—The president announced that the Rev. C. D. P. Davies was giving a demonstration of his system of testing parabolic mirrors.—Other papers were taken as read.

Mathematical Society, December 14.—Prof. A. R. Forsyth, president, in the chair.—Some difficulties in the theory of transfinite numbers and order types: the Hon. B. A. W. **Russell.** The paper deals with the difficulty as to "inconsistent aggregates" and with the question concerning the axiom that every aggregate can be well ordered. It is shown that the difficulties belong rather to logic than to mathematics, and various methods are explained by which steps may be taken towards resolving them.—On well-ordered aggregates: Prof. A. C. **Dixon.**—The Hessian configuration and its connection with the group of 360 plane collineations: Prof. W. **Burnside.** The configuration is that of 9 points in a plane which lie 3 by 3 on 12 straight lines. The first part of the paper is occupied with the establishment of the configuration, and of the nature of the group for which it is invariant, from a geometrical point of view. In the second part it is shown how to construct a configuration of 45 points which lie 5 by 5 on 36 lines, 4 by 4 on 45 lines, and 3 by 3 on 120 lines. From the 45 points 10 Hessian configurations can be formed, and any two of these have one point in common. The configuration is invariant for a group of 360 collineations, which is simply isomorphic with the alternating group on six symbols.—On the representation of certain asymptotic series as convergent continued fractions: Prof. L. J. **Rogers.** The paper is concerned with asymptotic series which represent integrals of the type $\int_0^\infty f(t)e^{-t/x}dt$, where $f(t)$ is a polynomial or is representable by a power series.—The theory of integral equations: H. **Bateman.** The theory is that of the construction of a function ϕ which shall satisfy an equation of one of the forms

$$(1)\quad f(x)=\int_a^b \kappa(x,t)\phi(t)dt,$$

$$(2)\quad f(x)=\phi(x)-\lambda\int_a^b \kappa(x,t)\phi(t)dt,$$

where f and κ denote known functions and λ is a constant. It is shown how to reduce the solution of a linear differential equation to an integral equation of the second type, and that, if is discontinuous in a certain way, a solution of the equation of the first type exists and can be determined.—The imaginary in geometry: J. L. S. **Hatton.**—On a new cubic connected with the triangle: H. L. **Trachtenberg.**

Anthropological Institute, November 21.—*Exhibitions.*—Collection of photographs from Arizona: J. S. **Chase.** These included typical types of the natives, and also illustrated the Mogui snake dance and other ceremonies.—Collection of objects from Siam, including weapons, pottery, and musical instruments: M. **Bidder.**—*Paper.*—Boomerangs: N. W. **Thomas.** The author explained the difference between the return and non-return boomerang, and showed the reasons for the peculiarity of the former kind. Diagrams of the different flights were exhibited, as well as a large collection of Australian boomerangs and African throwing knives.

CAMBRIDGE.

Philosophical Society, November 13.—Prof. Liveing in the chair.—Polarisation phenomena at Guelma in the eclipse 1905 August 30: H. F. **Newall,** F.R.S. The visual observations combined with the photographic records proved that the plane of polarisation of the light diffused by the earth's atmosphere during the eclipse was very nearly horizontal. Photographic records, obtained with a Savart polariscopic camera for the purpose of quantitative measurements of the relative amounts of polarised and unpolarised light in the corona, showed that the polarised portion of the atmospheric light was equal in intensity to the radially polarised portion of the coronal light at a distance of about $1\frac{1}{2}$ diameters from the sun's limb. Thus the phenomena of a radially polarised corona seen through a plane polarised atmosphere are somewhat complicated. The results obtained by photographing the corona through a large Nicol prism, which was set to transmit successively the vertical component and two components which were inclined on each side at 45° to the vertical and consequently perpendicular to one another, not only show the strong radial character of the polarisation of the corona, but also seem to suggest that there is a selective action, and that the prominent streamers of the corona are markedly polarised. A photograph taken with a new form of polarising spectrograph shows a very marked difference in the intensities of the tangential and radial components; but a curious feature in it is that the Fraunhofer lines are not detected in either spectrum, though the conditions are such as must be regarded as very favourable for their detection.—Suggestions for a theory of the Milky Way and the clouds of Magellan: A. R. **Hinks.**—The effect of the lunar deflection of the vertical on latitude observations: B. **Cookson.** The attraction of the moon would cause the plumb-line to be deflected through an angle of $0''.02$ at a maximum, if the earth were a rigid body. It is pointed out that observations made for the purpose of determining the constant of aberration and variation of latitude by Küstner's method are suitably arranged for showing this deflection. A series of observations made at Philadelphia is discussed, but fails to show the direct lunar effect, though it shows an oscillation with a period of half a lunar day, which may be due to the attraction of the ocean tides.

November 27.—Prof. Marshall Ward, president, in the chair.—Some experiments on Canal-strahlen: Prof. **Thomson.** Experiments were described showing that when the stream of positive ions which form the Canal-strahlen fall on a solid, slowly moving kathode rays start from the part of the solid struck by the positive ions; again, metals struck by the Canal-strahlen disintegrate, and the metal is deposited on the walls of the discharge tube; ionisation was shown to accompany the passage of the Canal-strahlen. It is suggested that the reason the α particles of radium lose, as shown by Rutherford, their power of ionisation when their energy falls to a value which, though less than the initial energy possessed by the α particles, is enormously greater than the positive ions in the Canal-strahlen, may be that the α particles lose their charge when their velocity falls below a certain value by combining with a negative corpuscle; the value of this velocity is calculated, and it was shown to be between 10^8 and 10^9 cm.-sec. The spectra produced by Canal-strahlen were discussed, and it was shown that though these rays give rise to the sodium lines when they fall upon sodium salts, they do not do so when they fall upon the pure metal.—Experiments on the retention of an electric charge by gases: W. A. D. **Rudge.**—The effect of hydrogen on the discharge of electricity from hot platinum: O. W. **Richardson.** An account of experiments on the ionisation produced by a platinum tube in air when hydrogen was allowed to diffuse from inside the tube. The negative ionisation was unaffected, whereas the positive was increased by an amount proportional to the quantity of hydrogen diffusing through. The experiments indicate that the increase in the negative leak produced by an atmosphere of hydrogen is due to a change produced by the latter in the surface of the metal, possibly by the formation of an electrical double layer. The experiments on the positive ionisation tend to show that the hydrogen dissolved in the metal is in the form of positive ions.—On colour-inheritance in rats: L. **Doncaster.** Among the varieties of domestic rats there are, in addition to albinos, two types of colour, black and brown (grey). The colour in either case is distributed in one of three very constant patterns; rats may be (*a*) self-coloured, with or without a small white mark on the chest; (*b*) coloured above and white below; (*c*) piebald, with coloured "hood" and back-stripe, elsewhere white. In inheritance, brown is dominant over black, and both over albino. Albinos may bear the black or brown determinant, as in mice, rabbits, &c. When a self-coloured rat is crossed with a piebald, the young have the intermediate pattern (*b*); this is a heterozygous form, and when two of this type are bred together they throw selfs, piebalds, and heterozygous young like themselves. Albinos can also bear pattern-determinants, so that an albino bearing "self" bred with a piebald throws heterozygous young of type (*b*). Self-coloured rats may be entirely coloured or may have a white mark on the chest, but since either form can throw the other, it appears that this is a fluctuating character, and that the pure "self" and white-marked form are not allelomorphic with one another.—A preliminary communication on the life-history of *Pleistophora periplanetae* (Lutz and Splendore): W. S. **Perrin.**—On the osmotic pressure of alcoholic solutions: P. S. **Barlow.**—Two wheels connected by an axle rolling on a rough horizontal plane: G. M. K. **Leggett.**—A series of optically active nitrogen compounds containing the allyl group: Miss M. B. **Thomas** and H. O. **Jones.** The investigation of the relation between the constitution and rotatory power of substituted ammonium ions is being continued. A series of five compounds containing the phenyl, methyl, and allyl groups, together with the ethyl, propyl, isopropyl, isobutyl, and isoamyl groups respectively, has been examined.

PARIS.

Academy of Sciences, December 11.—M. Troost in the chair.—On the distillation of gold, the alloys of gold with copper and tin, and on a new method of preparation of the purple of Cassius: Henri **Moissan.** Gold can be easily distilled in the electric furnace, its boiling point being higher than that of copper, but lower than that of lime. By condensation on a cold tube, the vapour is condensed partly in the form of moss gold, partly as microscopical crystals. The general properties of the condensed gold agree with those of finely divided gold. In the alloys of gold and copper, or gold and tin, the copper and tin distil before the gold. By distilling an alloy of tin and gold, a purple of Cassius is obtained in the dry way.—Nepheline syenites from the Los Islands (French Guinea): A. **Lacroix.** The various types of syenite in these islands are discussed in detail, and complete analyses are given for three typical specimens.—The habits of bees and the colours of flowers: Gaston **Bonnier.** According to the author, the contradictory experiments of various observers on the relations between bees and colour are due to a lack of knowledge of the habits of bees. There is a division of labour among the honey-fetching bees, the duty of those first issuing from the hive being to seek out honey, and not to fetch it. After a certain hour all the bees are engaged in fetching and carrying, and none in hunting for fresh sources of honey, and hence in selective experiments of this sort quite different results can be obtained according to the hour of the day fixed for the experiment. The author's own experiments lead to the conclusion that the bees are not influenced by colour in their search for honey.—Spectroscopic observations made during the eclipse of the sun of August 30, 1905: P.

Salet. The spectrum of the prominences showed lines characteristic of helium, coronium, hydrogen, cerium, titanium, calcium, and iron.—On the new Giacobini comet: M. **Giacobini.** Observations and elements of a comet discovered at Nice on December 6.—On the convergence of the regular continued fractions of the function $F(h,1,h',u)$: H. **Padé.**—On the problem of the motion of a homogeneous fluid ellipsoid all parts of which attract each other according to the law of Newton: W. **Stekloff.**—The theory of a solitary wave which is propagated along a horizontal elastic tube: A. **Boulanger.** The evaluation of the magnifying power of microscopic objectives: L. **Malassez.**—On the co-existence of paramagnetism and diamagnetism in the same crystal: Georges **Meslin.** Experiments are described proving the existence of both para- and diamagnetism in the same crystal of pyrrhotine, and the continuous variation of the magnetic susceptibility with the direction. The action of a magnetic field on the Goldstein rays (Canal-strahlen): Henri **Pellat.** Some curious and somewhat paradoxical experiments on the Goldstein rays are described. In magnetic fields of low intensity the rays behave exactly like positively charged particles. As the intensity approaches 1000 Gauss, the whole tube appears uniformly luminous, and if the magnetic field is still further increased, the luminosity contracts, but the deviation is in the opposite sense to that which is produced in magnetic fields of lower intensity. The author is at present unable to offer any explanation of the phenomenon.—A new arrangement for obtaining a monochromatic image of a source of light: Albert **Nodon.**—On the solution of platinum in sulphuric acid: Marcel **Delépine.** The action of sulphuric acid containing potassium sulphate upon platinum foil has been studied. The action increases with the amount of potassium sulphate present, probably on account of the higher boiling point of the mixture thus obtained. Ammonium sulphate reduces the solvent effect.—On two iodomercurates of lithium: A. **Duboin.**—On a new compound of fluorine and bromine: Paul **Lebeau.** Fluorine unites directly with bromine giving a compound BrF_3. This trifluoride, in which the bromine may be considered as trivalent, is a colourless liquid solidifying on cooling, and melting at 4° C. The chemical activity of this substance is very great, resembling that of fluorine.—Researches on the formation of metallic lustre on the surface of pottery: L. **Franchet.**—On the bromoborates of calcium: L. **Ouvrard.**—On the limiting states of some dissolved chromic salts: Albert **Colson.**—The action of phosphorus pentachloride on β-naphthol: E. **Berger.** Phosphorus pentachloride acting on β-naphthol at temperatures below 130° C. gives a good yield of the ether, $C_{10}H_7—O—C_{10}H_7$; at temperatures above 135° C. β-chlornaphthalene is formed. The yields are not high, but on account of the low prices of the materials it forms a good preparative method.—On some derivatives of anthracene octahydride and on the perhydride of anthracene: Marcel **Godchot.**—The synthesis of dihydrocamphoric acid: G. **Blanc.**—On acetylcyclohexanone: Georges **Leser.**—Anatomical and physiological modifications produced in certain tropical plants by a change of the place of growth: D. **Bois** and I. **Gallaud.** The necessity of taking into account the anatomical changes produced by a change in the environment of a plant is pointed out, and the errors in classification which may arise. The study of the factors producing these changes is also important in the acclimatisation of plants of commercial value. Studies on the influence of light on the development of green plants, carbon dioxide being absent and amides added to the soil: Jules **Lefèvre.**—The granular eruptive rocks collected in Grahamsland by the Antarctic expedition of Dr. Charcot: Ernest **Gourdon.** Exploration in eastern Africa: Maurice **de Rothschild.**—On crystallised hæmatin: MM. **Piettre** and **Vila.** Crystallised oxyhæmoglobin, from the horse, was split up into an albumenoid, globin, and crystallised hæmatin, the pigmented material of the blood, analyses of the latter being given and compared with earlier analyses of amorphous hæmatin of other observers.—The moderating action of catalase on the oxidations produced by extracts from animal tissues: F. **Battelli** and Mlle. L. **Stern.**—On some mineral compounds which behave like the liquefying diastase of malt: J. **Wolff.**—The diastatic hydrolysis of xylane: Gaston **Seillière.** In some molluscs and insect larvæ there exists a diastase capable of hydrolysing xylane to xylose, and for which the name of xylanase is proposed. It is probable that this substance plays an important part in the nutrition of these animals.—The geology of the eastern Pyrenees: Léon **Bertrand.**—On Fontaine-l'Evêque and the caverns of the plain of Canjuers: E. A. **Martel** and M. Le Couppey **de la Forest.**

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 21.

THURSDAY, DECEMBER 28, 1905.

THE CHEMISTRY OF PLANTS.

Biochemie der Pflanzen. Zweiter Band. By Prof. Dr. Fr. Czapek. Pp. xii + 1026. (Jena: Gustav Fischer, 1905.) Price 25 marks.

THE first volume of this work was reviewed some months back (NATURE, June 22, 1905, vol. lxxii. p. 169), when its general scope and nature were given, and certain remarks were made with respect to its style and structure which are equally applicable in the case of the second volume; hence no recapitulation of these is here necessary.

The material of the present volume is roughly double that of the first, and its magnitude is gauged by the number of the pages given above.

As the first volume dealt with the distribution, metabolism, and metastasis of aliphatic substances, so the second deals with proteinic compounds and the biochemistry of nitrogen, with derivatives of closed rings, and with the inorganic constituents of plants; further, the resorption of oxygen, and phenomena of irritability regarded in their biochemical aspect, also receive detailed attention.

The contents of the volume are divided into thirty-eight chapters, which are followed by addenda and corrections, an index of the subject-matter, another of the names of plants, and finally a list of misprints and errata.

The book opens with a chapter on the general chemistry of proteins. The succeeding chapters are grouped, more or less, into sections under the following headings:—the proteinic metabolism of the Fungi and Schizomycetes, that of seeds and of other organs and groups of plants, the ultimate nitrogenous and anitrogenous products of metabolism, the resorption of oxygen, pigments, ubiquitous cyclic and acyclic compounds, the metabolism of inorganic substances, and lastly the stimulatory action of various bodies.

The opening chapter gives a suitably condensed and, as regards the main outlines, comprehensive account of the chemical and physical properties of proteins and the products of their decomposition. In the succeeding two sections the nature of the proteins occurring in different plants and different organs is discussed, and an account is given of the modes in which these compounds are synthesised and rendered available for metabolic processes when external to the plants. The absorption of soluble nitrogenous compounds is also considered in these sections, which are, in fact, concerned with the general metabolism of nitrogenous substances throughout the vegetal kingdom.

In the next section the ultimate nitrogenous products of metabolism are discussed in detail under the following headings:—oils, purine-bases, nitril-glucosides, bases derived from pyridine and chinoline, and derivatives of indol.

The section devoted to resorption of oxygen deals biochemically with ordinary respiration and the acquisition of chemically-bound oxygen.

Following the sections devoted to pigments, substances of universal occurrence, and the ultimate anitrogenous products of metabolism, is an exhaustive treatment of the metabolism of inorganic constituents in various divisions and organs of plants, and of the modes of their occurrence.

The text concludes with an interesting and well-written account of the stimulatory action of various substances in relation to different vital processes such as fermentation, respiration, photosynthesis, protoplasmic streaming, nuclear division, growth, reproduction, &c.

An idea of the degree of comprehensiveness and detail of the work is afforded by the titles of some of the minor chapters, namely, the proteinic metabolism of pollen-grains, that of fruits, of mosses, of algæ; the inorganic metabolism of subterranean reserve-organs, the inorganic constituents of buds, those of wood, of bark, of algæ, of pollen-grains, of fruits.

The main outline of this volume may be said to have been given in the preceding paragraphs.

What appears most striking here, as in the first part, is the colossal amount of material collected; the labour involved must have been enormous. A result of this is the resemblance of the text of many pages to some highly-condensed abstract, as it is in such places practically a long succession of facts—or reputed facts.

Like the first volume the second is singularly free from misprints and errors of nomenclature. But one scarcely expects to read in a precise botanical work—as on p. 818—of the "stem" and "leaf" of Laminaria, a plant that has neither stem nor leaf. Moreover, in no case has Prof. Czapek attached to the name of a plant that of its author; this omission is certainly a common one in botanical works, but in spite of this most deplorable, since in many cases in which this index fails the nature of the plant is doubtful.

Many useful tables of figures occur throughout the work, and orientation with respect to groups of chemically-allied substances is much facilitated through the interpolation of numerous graphic formulæ in the text.

The literature dealing with the subjects treated seems to have been searched with considerable thoroughness, and that which is most essential referred to in relatively suitable proportion. Possibly those who have made the various branches touched upon their special study might detect important omissions, but so far as lay in the power of one man Prof. Czapek seems to have been very successful in citing all that is most important. The reviewer misses reference to Schjerning's important paper on proteohydrolysis that appeared about three years back in the publication of the Carlsberg laboratories, and he sees no mention in this volume of the work by F. F. Blackman on gaseous exchanges, or of that by Cornevin on the degree of immunity of plants to vegetal poisons of autochthonous and alien origin.

Prof. Czapek is not of the opinion that the acceleration of oxidative processes by various metallic salts in association with colloids is likely to result in modification of existing notions of oxydases. The matter

is one, however, that requires extended quantitative and qualitative treatment. The supposition that an action is *entirely* due to a colloid, because the action ceases on separation of the colloid from the system, is an error commonly made by physiologists, due to the omission of taking into account phenomena of adsorption, and the complete alteration of conditions produced by the change.

There can be no doubt as to the value of this work in its completed form; it traverses practically the whole of physiology in its chemical aspect, so far as it is now possible to do so, and illustrates in an excellent manner the results that have been produced through application of chemical methods to physiological problems; it is the first extended treatise of the biochemistry of plants, and as such fills a void that was distinctly appreciable, and moreover fills it in a manner that places all vegetal physiologists under great obligation to its author.

F. ESCOMBE.

EXPERIMENTS WITH EXPLOSIVES.

New Methods of Testing Explosives. By C. E. Bichel. Translated and edited by Axel Larsen. Pp. 62. (London: Chas. Griffin and Co., Ltd.) Price 6*s.* net.

IN collecting together and translating the papers on the researches carried out in the laboratory of the Carbonite Explosives Company, Hamburg, the translator has given to English readers a valuable and interesting little volume. The title is perhaps a trifle misleading, but the whole-scope of the work may be seen from the following quotation:—"(1) Why does a smaller quantity of one explosive than another cause ignition of fire-damp? (2) What are the incidental phenomena and the influences tending to promote such result? (3) In what manner do they co-operate in producing it?"

Appreciating the fact that it is desirable to work with quantities as nearly as possible approaching those employed in actual practice, special apparatus has been constructed, so that for the particular explosives dealt with we now have details obtained from experiment on a much larger scale than any hitherto adopted. In some cases charges of gunpowder as great as 1500 grams were exploded, and for the higher explosives often 300 grams. Even for the calorimetric determinations the bomb had a capacity of 30 litres, which was capable of taking a charge of 100 grams. There must always, however, be some risk with heavy charges of recording undue pressures, a point to which Noble has directed attention.

The actual pressures, gas volumes and composition of the products were determined from charges fired in Bichel's apparatus, the pressure being recorded by a piston indicator working on a drum. The record is really in excess of the true pressure, but it is stated that the indicated pressure is rarely more than two or three per cent. from the actual. The apparatus permits of variations of surface area for a definite charge, and so the cooling effect of the chamber may be eliminated. It appears that with this allowance the pressure at a given density of loading is proportional to that with higher densities. This, however, may not be strictly true with very high densities.

The actual temperature at the moment of explosion was calculated from the heat developed, the composition of the products and their specific heat, in the usual manner, but all such calculations are uncertain owing to doubt as to the specific heats of gases at these high temperatures, and the impossibility of taking into account dissociation. The possibility of fitting a thermo-junction into the Bichel apparatus might be worthy of consideration, for although the results cannot approach actual values, yet the relative temperatures recorded would probably serve as a useful check on those calculated. Macnab has already employed the thermo-junction for this purpose.

In connection with the safety of explosives for mining, undoubtedly the length of the flame, its duration and temperature are of the greatest importance. The two former were recorded photographically, a quartz lens being used. Some excellent plates of the flames are reproduced. A factor deduced from the ratio of the flame duration to the detonation time, termed the "after-flame ratio," is shown to have the greatest influence on the ignition of fire-damp, and a most instructive diagram shows the temperature developed, the length of flame, and the "after-flame ratio" for the explosives examined.

In considering the efficiency of an explosive the author makes a distinction between the dynamic action, due to the projectile-like action of the products on the surrounding surfaces, and the static energy, deduced in the usual manner from the volume occupied by the products at the calculated temperature of explosion. It certainly seems that a more rational classification is thus possible than when the two are considered together, and the results are claimed to be fairly in accordance with those obtained in actual practice.

The general bearing of the work on the question of safety is clearly dealt with, and four very complete tables give a mass of information relating to the explosives examined.

Sufficient has been said of the contents of the book to convince those interested in the subject of its great value. It deals almost exclusively with mining explosives, but it would certainly be of very great interest if the investigations could be extended to military explosives, for the author has such valuable apparatus at his disposal that experiments on this large scale could not fail to give much valuable information.

J. S. S. B.

CAUSALITY AND THE HUMAN WILL.

The New Science of Causation. By H. Croft Hiller. Pp. xiii+386. (London: The Walter Scott Publishing Company, Ltd., 1905.) Price 10*s.* net.

IF intrepidity were the prime essential of a philosopher, this work would be epoch-making, and its author would be a thinker of the first rank. He claims to have formulated a case—to his mind, abso-

lutely impregnable—against the intellectual foundations of empirical science. So impregnable, in fact, to the author's mind that he can afford to detail in the preface, with inimitable *naïveté*, his many discouragements in the preparation of the work the fact, for instance, that of eight Fellows of the Royal Society with whom he has communicated all have declined to read and criticise advance proof-sheets. Sir Oliver Lodge has even gently indicated that Mr. Hiller's previous works have not impressed him; the letter is printed in full as a kind of *imprimatur*.

Briefly stated, Mr. Hiller's main position is that causality resides solely in the human will, and not at all in matter, atoms, ions, ether, electricity, or any of the other entities with which modern science deals. What reality ordinary objects possess is not quite clear, but apparently the action which we ordinarily suppose them to effect really belongs to the human being using them. Thus "a knife is a fetish facilitating cutting," *i.e.* cutting could quite well be done by the unequipped human will, but human nature being weak finds it useful for ordinary purposes to rely on the God-determined illusion of knives and scissors. Food becomes unnecessary, or can readily be replaced by poisons. In fact, there is no poison or disease at all but thinking, or rather willing, makes it so, *i.e.* if the individual will, acting on its own initiative, has not endowed an object with such and such attributes, then the consensus of other human wills, acting through hypnotic suggestion, so endows it. In this way, we presume, Mr. Hiller would account for the occasional death of infants by accidental poisoning. Doctors not only cure diseases, but also create and propagate them.

Considerations of space forbid a statement of Mr. Hiller's doctrine of perception, with its singularly elegant terminology—top storey of mind, mnemonic storey, and the like. But a word of criticism must be added, even if it is foolhardy to rush in where eight Fellows of the Royal Society have declined to tread. So far as we can understand our author, he seems in too great a hurry to explain abnormal experiences. He revels in things that make our flesh creep, people whose staple diet is strychnine, "Katie King" apparitions, ghosts that have pulses and heart-beats. Now of course we should all like to build up absolutely exhaustive systems, but at present well-sifted evidence of the extraordinary is so difficult to procure, and the abnormal is so often exploited by charlatanism for private ends, that science, which is long and patient, will rather wait a little and concentrate itself upon the normal. Again, there is obviously a difference in the glory of fetishes; there is one fetish which facilitates cutting, and another which facilitates Marconigrams. Will Mr. Hiller seriously maintain that a consensus of even all existing human wills could interchange these at its pleasure? Why had we to wait until the twentieth century for radio-activity? Could a sufficiently strong will in the nineteenth have produced the same effects by means of shoe-blacking?

We gather from the preface that this attempt to prove the rest of the world insane is merely a provisional instalment of a greater work, to be entitled "Sic Transit Scientia"! So important an effort to overthrow the walls of the empirical Jericho must be carefully timed; we can only suggest as the most fitting date of publication the eve of the Greek Kalends.

IONS AND ORGANISMS.

Studies in General Physiology. By Jacques Loeb. 2 vols. Pp. xxix+782. (London: T. Fisher Unwin, 1905.) Price 31*s*. 6*d*. net.

THE two volumes of papers collected under this title form one of the most interesting and suggestive works that have been published on the subject. The bold idea, that by means of alterations in the composition of the solutions that bathe the tissues it is possible profoundly to affect not only metabolism and growth, but also such processes as fertilisation, has led to a series of experiments here recorded that are well worthy of careful study.

The material with which Prof. Loeb and his pupils have worked has been in the main organisms of such a size that the whole animal could be acted on by changes in the salts dissolved in the water in which the animal lived. Most of the experiments were made with either the embryos or eggs of marine animals belonging to the groups of Annelidæ, Echinoderms and their allies; some were on fish embryos, some on hydroids, and the earlier experiments, which seem to have furnished the author with the leading idea for these researches, frog's muscle. This idea, shortly summarised, is that the changes in the composition of the solutions are effective on account of the properties of the various ions added or subtracted, and that by varying these one can control the various biological processes. The control is supposed to be direct, and ions are even termed "toxic" or "antitoxic" according to their suggested action on any process—for example, Sodium ions are "toxic," because they prevent the development of fundulus ova, Calcium ions are "antitoxic" because they neutralise this action.

The experiments which have perhaps attracted most attention are those on artificial fertilisation. Addition of HCl to the water in which the eggs of starfish (Asterias) were suspended caused them to develop parthenogenetically; similarly Ca was efficacious for the eggs of Amphitrite, KCl for Chaetopterus, and either KCl, NaCl, or even evaporation of sea water for the eggs of Arbacia, an Echinoderm. As to the accuracy of the observed phenomena, most of Prof. Loeb's readers will accept the evidence here adduced; whether the results bear the importance attached to them is a more open question. The author himself points out that these eggs are naturally on the brink of parthenogenetic development; in fact, if left to themselves they usually begin to segment spontaneously, and the effect of the addition of the various ions is only to hasten a naturally occurring process. It perhaps asks too much, but one regrets that the experimental difficulties so far seem to have prevented any of the parthenogenetic animals from attaining adult life.

For the rest, one notices that Prof. Loeb derives his inspiration from internal sources, and that quotations from other authors and from the *Archiv f. allgemeinen Physiologie* occupy but a small place. What, however, is more natural, if an author has sufficient new and interesting material to draw upon, than to confine himself to his own observations? Enough has been said to convey our impression that the two volumes now under review well repay careful consideration, and that the facts recorded therein mark an important advance in our knowledge of general physiology.

OUR BOOK SHELF.

Civil Engineering: A Text-book for a Short Course. By Lieut.-Col. G. J. Fiebeger, U.S. Army. Pp. xiii+573. (New York: Wiley and Sons; London: Chapman and Hall, Ltd.) Price 21*s.* net.

THIS text-book on civil engineering is especially intended for the use of cadets of the U.S. Military Academy, whose duties later are often those of a civil engineer. A short course on this subject is therefore provided, and this work is evidently based on the author's lectures at West Point. It is natural to expect that in these circumstances the treatment of the theory of structures will be that of the engineer rather than of the pure mathematician, and that it will be of the simplest possible character. It is therefore disappointing to find that this section is treated in an almost purely academic way involving much chasing of x, with little or no appeal to physical ideas. This is well illustrated by chapters iv. and v., mainly on the deflections of beams under various conditions of loading and fixing, a section of forty-nine pages, involving one hundred and ninety-three numbered equations, with little or no indication of their physical meaning. A semi-graphical treatment would have been far preferable for military cadets studying this subject with a view to practical applications, and this remark applies to other parts of the book; thus we should imagine that a student, after reading chapter iii., on the flexure and bending of beams, would have considerable difficulty in calculating the moment of resistance of a section such as a bridge rail, a perfectly easy problem by a semi-graphical method and one likely to require solution by an officer who "in an isolated station finds himself called upon to act as an engineer and constructor of buildings, roads, and bridges," with possibly a miscellaneous collection of materials.

In the purely descriptive part of the book the author is much happier, and a great deal of valuable information is contained in this section. Throughout the book the author is somewhat free with his terms; thus his use of the word molecule leads him to the statement that "the unit shearing stresses on the vertical and horizontal faces of the elementary molecule are equal," while other terms, such as "curve of mean fiber" and "spontaneous axis," might be amended with advantage. E. G. C.

Thunder and Lightning. By Camille Flammarion. Translated by Walter Mostyn. Pp. 281. (London: Chatto and Windus, 1905.) Price 6*s.* net.

THIS book contains no translator's preface, so one is apt to believe that it is a translation of M. Flammarion's "Les Phénomènes de la Foudre." A comparison of the two volumes shows that the titles of the chapters in each are identical, with the exception of two chapters of the French work which are merged into one in the translation. A closer examination leads one to conclude that the English edition is a very abridged form of the French, and the illustrations, which number fifty-four in the latter volume, only total nine in the translation. It is clear, therefore, that the two volumes are very different from each other, although one is supposed to be a "translation" of the other, since nothing is said to the contrary.

Apart from the above mentioned differences the English translation is well done, and will be found very interesting reading. The greater portion of the book is devoted to the effects of lightning flashes, and a large number of examples are described. Thus we have the effects on mankind, animals, trees, plants, metals, objects, and houses. Many instances are narrated of the vagaries of fireballs, and two chapters are devoted to atmospheric electricity and storm-clouds, and the flash and the sound.

Photography for the Press. By the editor of *The Photogram.* Second edition. Revised and very largely rewritten. (London: Dawbarn and Ward, Ltd., 1905.) Price 1*s.* net. Cloth, 2*s.* net.

THIS very complete and practical book contains hints to the photographer who wishes to make use of his pictures for press purposes. The editors acknowledge that this is a new departure in photographic literature, but the fact that the present edition is the second indicates that a want has been supplied. So large is the number of illustrated journals, books, &c., at the present time, and they are still on the increase and likely to become much more numerous, that time and possibly disappointments will be saved to the photographer if he becomes acquainted with many of the hints included in the present issue. In addition to some general remarks about the relation of the editor and publisher to the photographer, practical field and workshop methods are also discussed. Interesting and valuable information on the copyright union, copyright law, permits to photograph, &c., are next taken up, and lastly there are lists of agents for press photograms, publishers of picture post-cards, and the principal illustrated periodicals with all up-to-date information, such as class of print preferred, size of page, date and time to which originals are usually received for current issue, &c.

From the above it will be gathered that the book is intended to serve a very practical purpose, and the editors have produced a book that will be serviceable to many photographers.

How to Know the Starry Heavens. By Edward Irving. Pp. xvi+313. (London: T. Fisher Unwin, 1905.) Price 8*s.* 6*d.* net.

THIS volume is, avowedly, not so much a text-book for astronomical students as "an invitation to read text-books on the subject," but while it contains a large amount of real information, we fear that the matrix is so bulky that the reader to whom the book is intended to appeal will find great difficulty in discovering and assimilating the real facts. After discussing the apparent motions of the heavenly bodies and the rival theories concerning them, the reader is conveyed towards α Centauri in "The Chariot of Imagination" in order to gain some idea of the cosmological insignificance of the earth and to view more closely the sun and his system. Then the author attempts to instil a concrete idea of the dimensions of the visible universe. To this end he gives about twenty different illustrations, each one under a prominent subtitle such as "A Pile of Blood Discs" or "A Spider's Web," the whole occupying about fourteen pages. Succeeding chapters deal with other astronomical subjects in a popular manner and with more or less convincing illustrations.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Magnetic Storms and Auroræ.

The observations of your correspondents Mr. Rowland A. Earp and Mr. R. Langton Cole, published in Nature of November 23 (pp. 79–80), remind me that an aurora was also visible here (Cape Breton Island, Nova Scotia) on November 15 about 6 p.m., Halifax time.

Although only faintly visible on account of the twilight and the condition of the sky, the aurora was evidently of considerable intensity, throwing up streamers to the zenith.

I looked out again at 7 p.m., but could detect no signs of auroral activity then. Occasional watch was kept upon the northern sky during the rest of the night in hopes of a recurrence, but nothing further was seen.

Alexander Graham Bell.

Beinn Bhreagh, near Baddeck, Nova Scotia, December 9.

With reference to a letter from Dr. Chree in Nature of November 30 (p. 101) upon the magnetic storm of November 15, it may perhaps be of interest to mention that, according to a notice in the newspaper *Finmarken*, the aurora of that day in Vardö (lat. 70° 22′) was by far the most splendid seen there for many years. It is described as bright red all over, and, when most vivid, forming a belt over the whole sky from south-west to north-east. At last, about 11 p.m., the light gathered in the southern sky, making the impression of a huge fire some forty kilometres away.

Here in Christiania the sky was overcast, except a low horizontal stripe in the north-west, where the vivid greenish light was moving to and fro about 7 p.m.

The Origin of Variations in Animals and Plants.

Having found much ambiguity in discussions of this subject, I have tried to formulate briefly the probable facts, as they appear to me.

(1) In the beginning, the germ-plasm was not separated from the somato-plasm, and hence it is assumed that "acquired characters" were inherited, and, we must suppose, still are by the protozoa. It seems probable, however, that the obvious effects of the environment were not permanent, but were recovered from in a few generations of cells or individuals, much as they are frequently recovered from in the metazoa during the life of a single individual. When they were too severe, they probably resulted in the death of the affected individuals or strains. In other words, there has been no regular "inheritance of acquired characters" among the protozoa any more than among the metazoa.

On the other hand, it seems reasonable to suppose that there were other more subtle effects, which in various slight ways *changed the molecular arrangements or composition of the plasm*, and effects so produced would be permanent until further changes of a similar nature took place.

The extraordinary permanence of type of protozoan and protophytan species, both in time and space, compels us to discard the idea that they are easily modified by external or any other conditions; while their marvellous diversity shows that they are *capable* of extraordinary modification. What causes the molecular changes (presumably nobody denies that they take place) is not apparent to us, partly because the phenomena must be very difficult (or impossible?) to demonstrate, and partly, perhaps, because they have been overlooked, all attention having been given to the obvious but less significant changes. Recent physical science has made us familiar with all sorts of subtle influences, and we do not know how any of them might affect the complex molecule of a living creature. Substances which hitherto behaved in a perfectly well known manner have given us surprises when we placed them in the presence of something new. So it may well be with the living molecule, and what we call "great changes in environment" may be nothing at all to it, compared with subtle influences which entirely escape our observation.

(2) In the first place, the molecular changes may have been good, bad, or indifferent (as tested by the prosperity of the creatures); but very soon selection would get in its work, and *those types of plasm which responded in certain ways to the more usual influences would be perpetuated*. Hence it would presently be found that variations were no longer indefinite, but were in certain prevalent directions—as they assuredly are.

(3) The fact that protoplasm shows such very definite tendencies low down in the scale of life (so that the hydrozoa, for example, seem wonderfully prophetic of subsequent evolution) might be used as an argument that life did not originate upon this earth, but came here with a long history already behind it.

(4) In the metazoa the matter is immensely complicated, because we have in each individual not one, but a large number of more or less independent variables. Nevertheless, I cannot doubt that the germinal elements are, as I have supposed in the protozoa, caused to vary (and nobody disputes the variation) by external influences; yet, from the selection and evolution of ages, their reactions have become so definite that we cannot see in them anything but "the nature of the beast."

(5) Since those germs would be selected (through their somata) which reacted in such a way as to produce the most favourable variations, it becomes easy to see why certain kinds of variation may be carried *beyond* the point of maximum utility. They are like habits, which may be formed in response to certain needs, but which afterwards become tyrannical, because the individual has acquired the property of responding to particular stimuli, and cannot stop when the stimuli become more numerous, or the effects accumulate unpleasantly.

(6) The fact that certain genera (*e.g.* Rubus, Aster, Agriolimax) are extremely prolific in species in some regions, and very little so in others, seems to show that some external influences have been at work in the former case and not in the latter. We may also direct attention to the effects of changed conditions in producing variability (*e.g.* in *Helix nemoralis*), and to the evolution of similar types in different regions.

(7) It may well be that the *appearance* of characters in the soma does not always or often follow in the generation after the germ is affected (*cf.* Nature, February 16, p. 366).

An Acoustical Method for the Demonstration of the Magnetism of Liquids.

One end of a glass tube, about 5 mm. internal diameter and 1 mm. thick, is heated in a blowpipe flame until the molten end contracts to a round nozzle, leaving a small aperture of less than half a millimetre at the middle. The other end of this tube is connected by a caoutchouc tubing to an air-bag of considerable capacity, which is pressed by a constant weight. The nozzle is wet with a drop of liquid. By opening the cock of the air-bag, the air escapes through the nozzle and produces a clear musical sound, the pitch of which depends upon the dimensions of the nozzle as well as the quantity and the nature of the liquid; it varies also with the pressure of the air inside and the inclination of the tube to the vertical.

If the nozzle, wet with a magnetic liquid, be brought close to the conical pole-piece of a strong Faraday's electromagnet and the field excited, the pitch of the sound changes more or less according as the magnetic susceptibility of the liquid and the gradient of the field is greater or less. With concentrated solution of ferric chloride or manganese chloride, a change amounting to an interval of a third is easily obtained.

The details have been published in the *Proceedings of the Tokio Physico-mathematical Society*, vol. ii., No. 26.

THE PANAMA CANAL.

IN the issue of August 24 a review was given of General Abbot's book on "Problems of the Panama Canal," published this year; and in this book the construction of a canal with locks across the Isthmus of Panama, in preference to a sea-level canal, was strongly insisted upon. The October number, however, of the *National Geographic Magazine*, published in Washington, contains an article on "The Panama Canal," by Rear-Admiral Colby M. Chester, U.S.N., in which the advantages of a sea-level canal are quite as urgently advocated. Accordingly, the only points which have hitherto been definitely settled by the United States Government assuming the responsibility for the construction of the canal, are the final selection of the Panama route for the inter-oceanic canal and the consequent abandonment of the rival Nicaragua scheme, and the certainty of adequate funds being available for the completion of the Panama Canal, the want of capital having proved the most serious obstacle to the progress of the works when under the control of a private French company.

FIG. 1.—The Culebra Cut, Panama Canal looking North.

There are undoubtedly several difficulties connected with this enterprise which have still to be overcome, such as scarcity of labour and unsanitary conditions in a proverbially unhealthy tropical climate; the vast amount of excavation that has to be accomplished in cutting through the high central ridge constituting the divide between the Atlantic and Pacific watersheds (Fig. 1), composed in the higher portions of treacherous strata exposed to an exceptionally heavy rainfall; and the control of the great torrential floods of the river Chagres cutting in several places across the line adopted for the canal, which follows the valley of the river along the Atlantic slope. These impediments, however, in course of time, by the help of ample funds, the progress of sanitary science, the great improvements effected in excavating and dredging plant (Fig. 2), and the increased experience gained in the construction of reservoir dams, should not prove insurmountable. In reality, the question which at the present time demands a definite and early decision is whether the canal is to be constructed with a summit-level a considerable height above sea-level, to be reached by means of locks on each slope, or is to be excavated down to a sufficient depth to form a sea-level canal with only a regulating lock, $4\frac{1}{2}$ miles from the Pacific coast to Panama, to prevent the tidal rise in the Pacific Ocean of $21\frac{1}{3}$ feet at springs creating injurious currents into and out of the canal.

When the Panama Canal scheme was started at Paris in 1879, M. de Lesseps insisted that it should be constructed at sea-level, like the Suez Canal; and the works were commenced in 1881 on that basis, relying upon the eventual success of the earlier work, without adequate preliminary investigations, and without due consideration of the differences in the conditions of the two sites. In 1887 the unexpectedly large cost and slow progress of the works led the canal company to diminish considerably the amount of excavation by the introduction of locks, thereby effecting a large reduction in the ultimate expenditure, and in the time required for the completion of the canal, as can be readily appreciated by a reference to the longitudinal section of the canal with locks (Fig. 3).

Photograph by W. P. Tisdel.

FIG. 2.—A Steam Shovel at work in the Culebra Cut, Panama Canal.

This is the principle upon which work on the canal since that time has been conducted, with modifications from time to time in the proposed summit-level; it was followed, after the failure of the old company in 1888, by the new company constituted in 1894, so far as their limited funds permitted; it was approved by the various French Commissions which reported on the canal; and it was adopted by the International Isthmian Canal Commission of 1899–1901, which submitted to Congress the design shown by the accompanying longitudinal section and plan. This design consists of a summit-level $21\frac{1}{2}$ miles long, with its water-level 82 to 90 feet above mean sea-level, reached from the sea-level portion of the canal on the Atlantic side, 16 4-5 miles long, by two adjoining locks at Bohio, and from the sea-level section on the Pacific side, about $8\frac{1}{2}$ miles long, by a lock at Miraflores arresting the tide and raising the water-level of the construction of the Panama Canal," in which a sea-level canal is recommended, thereby abandoning the proposals of all the engineers who had previously studied the question since 1888, and reverting to the original scheme of M. de Lesseps. This project consists of a canal with a bottom-width of 150 feet, a minimum depth of water of 35 feet, and twin tidal locks at Miraflores having an available length of 1000 feet and a width of 100 feet; and it is estimated that this canal could be completed in ten or twelve years at a cost of 230,500,000 dollars, the Chagres River being controlled by a dam at Gamboa, forming a lake from which the surplus waters would be discharged by a tunnel through the dividing ridge into another river-basin. The committee further urges that if a canal with locks should nevertheless be preferred, its summit-level should in no circumstances have its

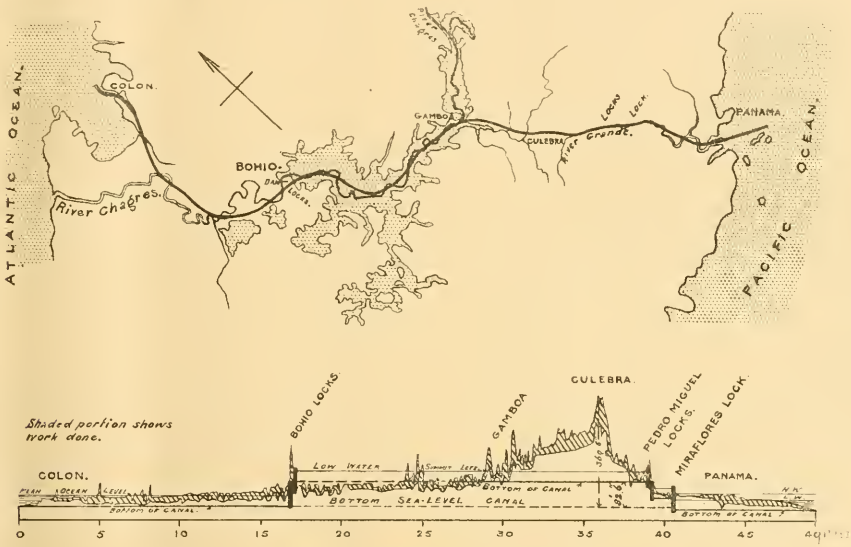

Fig. 3.—Panama Canal. Scheme with Locks. Commission of 1899–1901. Plan, Scale 1/600,000. Longitudinal Section, Horizontal Scale 1/600,000, Vertical Scale 1/6,000.

canal 30 feet above mean sea-level in a reach only $1\frac{1}{3}$ miles long, and two adjoining locks at the end of this reach connecting it with the summit-level (Fig. 3). For thirteen miles of the summit-level on the Atlantic side of the deep Culebra cutting, the canal would pass through a lake formed in the Chagres valley by a dam near Bohio, as shown on the plan, which would materially accelerate navigation along this part. In an article on "Progress of the Panama Canal," following the one by Admiral Chester, to which the plan and section here reproduced are appended, it is stated that this design with locks is the only one "on which the Canal Commission has as yet any authority to spend money."

The canal problem entered upon a new phase this year by the presentation last February of a report to the United States Isthmian Canal Commission by its Engineering Committee, which Admiral Chester terms "the first definite engineering plans for the water-level more than 60 feet above mean sea-level, and estimates that such a canal would cost 178,013,406 dollars, and a canal with only a 30-feet summit-level 194,213,406 dollars. The committee considered that a sea-level canal, which is free from the restriction imposed by locks on the volume of traffic and size of ships passing through them, and could easily be enlarged and deepened to accommodate an increased traffic and larger vessels, would be well worth the additional cost, and that in view of the great progress achieved in the rate of excavation, the period required for its construction would be moderate; and the opinion was expressed that though a canal with locks could be made which might subsequently be transformed into a sea-level canal, such a modification could only be effected at great inconvenience to navigation, and at an excessive cost. A scheme proposed by Mr. Bunau-Varilla with this latter object in view is described in the article on "Progress of

the Panama Canal," in which four locks on each slope would lead to a summit-level 130 feet above sea-level; and so by greatly reducing the excavation required in the Culebra cutting, the designer considers that the canal could be completed in four and a half years; and it is proposed that a very wide earthen dam should be formed at Bohio with materials dredged in excavating the canal, and conveyed through pipes to the site, thereby creating Lake Bohio, as shown on the plan. Another lake would be formed by a dam at Gamboa, outside the line of the canal; and this canal with locks is to be transformed into a sea-level canal, when required, entirely by dredging without impeding navigation, the dredgers being worked electrically by means of the water-power from the lake, the basin of which is to serve as a depositing ground for the dredged materials.

Admiral Chester, as an old naval officer, is naturally in favour of a sea-level canal, and supports his view by numerous extracts from the report of the Engineering Committee; whereas General Abbot, with his wide hydraulic experience, and the International Isthmian Canal Commission of 1899–1901 have advocated the construction of a canal with locks. In face of this conflict of opinion, it is natural that the United States Government referred the technical question last summer to an International Engineering Advisory Board, which recently visited the site; but, according to some newspaper correspondents, the members of this commission returned to Washington with discouraging and discordant views, so that their approaching report to the President will be awaited with much interest.

Undoubtedly, the conditions affecting the choice between a canal with locks and a sea-level canal have been modified by the United States Government having undertaken the construction of the canal, for the capital cost, which is a most important question for a private company, is of much less consequence to a Government, provided very material advantages, either as to facilities of navigation or a diminution in the expenses of maintenance, can be secured by a larger initial outlay; and, within certain limits, a prolongation of the period of construction is also of less vital importance. Too much stress, however, appears to have been laid in the report of the Engineering Committee of this year on the restriction offered by locks to navigation and increase in the size of ships, and too little account taken of the cost of enlarging a canal through an exceptionally deep cutting; and also probably much too sanguine a view is entertained of the period required for the large additional quantity of excavation necessitated by a sea-level canal, especially considering the uncertainties as to the supply of labour.

The only restrictions to navigation caused by a canal with locks are the time occupied in passing through them, and the possibility of vessels being built larger than they could accommodate; but the loss of time can be considerably reduced by suitable arrangements for filling and emptying the locks, their capacity for traffic can be readily increased by duplicating them when required, and their dimensions would naturally be made at the outset, like the tidal locks at Miraflores, adequate for any probable increase in the size of the vessels. Moreover, in the design shown on the plan, a great portion, if not the whole, of the time expended in locking would be recouped by the increased speed attained by vessels in traversing the thirteen miles of lake navigation. The advantage of facility of enlargement claimed for a sea-level canal really more rightly belongs to a canal with locks, provided the locks are constructed with due foresight of future requirements; for whereas the portions of the canal from the Atlantic to Bohio, and from the Pacific to Miraflores, with a total length of $25\frac{1}{4}$ miles, are the same in both schemes, owing to the excavation already accomplished, as shown by shading on the longitudinal section, about 11 miles of the lake portion in the canal with locks are considerably lower than required for giving 35 feet draught of water; whilst the remaining $10\frac{1}{2}$ miles of the summit-level of the canal with locks could be enlarged and deepened by 82 feet less depth of excavation throughout than would be necessary for the sea-level canal (Fig. 3).

The only serious objection that has been raised against the design shown in the illustrations is that the proposed dam near Bohio would have to be carried down 42 feet lower to reach a foundation of rock than was anticipated; but it seems almost incredible that the commissions appointed during the period that the New Panama Company had control of the works, the special mission of which it was to determine the feasibility and best means of completing the canal, should have neglected such an important investigation as the foundations for the Bohio dam. The statements that the Engineering Committee, in its report of this year, had presented the first definite plan for the construction of the canal, and that the American engineers had discovered a better site for a dam at Gamboa, which formed part of the original scheme, seem to indicate a bias against previous schemes, and a desire to appear to strike out a novel line. So far as information is at present available, and assuming that the Bohio dam can be executed as designed, it appears that a canal with locks would cost much less, be much sooner completed, and would be much more easily and cheaply enlarged than a sea-level canal, and that the greater facilities for navigation which might possibly be afforded by the larger scheme would, owing to the lake navigation offered by the other, be so insignificant as not to justify the additional cost, delays, and uncertainties the construction of a sea-level canal would entail.

Since the above article was written, the Advisory Board of Engineers has by a majority of three recommended the construction of a sea-level canal, three American and five foreigners voting in favour of it, and five Americans against, giving the preference to a canal with locks; but the report of the Board has not yet been published.

THE BIOMETRICS OF BRAIN-WEIGHTS.

"We are not endeavouring to discredit anthropology, but to furnish such branches of it as anthropometry and craniology with new tools—a little sharp-edged to the uninitiated who handle them incautiously—but which will raise anthropometry and craniology in the future into the category of the more exact sciences" (Karl Pearson, *Biometrika*, vol. iii., p. 153, 1904).

"There is a mathematical science of statistics which must be learnt, and papers dealing numerically with anthropometric and craniometric data which do not now apply this theory are simply outside the field of science" (*Biometrika*, vol. iii., p. 397, 1904).

It is not a raid, but a victorious invasion, that Prof. Karl Pearson and his school have made into the realms of anthropology, with the result that all that part of it which deals with men in the mass becomes an annex of the mathematician. The invasion occurred at a most opportune time; great collections of data which had been accumulated by the anthropologist threatened to bury him, for he had neither the method nor the appliances for welding them into a composite whole. Especially was this the case with the endless measurements of brain-weights obtained most laboriously by the anatomist and pathologist; they urgently required an application of the "mathematical science of statistics." Hence the series of articles which occupy the greater part of a number of

Biometrika[1] published a few months ago are particularly welcome; they lay a foundation for an exact knowledge of this subject.

For a hundred years and more anatomists have sought to establish a formula by which the mental ability of any individual could be predicted from an examination of the head or brain. The problem was found to be beset with difficulties and extremely complex. How was mental ability to be standardised and measured? Is the ability shown by any individual a fair and full manifestation of his endowment, or may it be presumed that much is latent and potential? Are all the nerve structures within the cranial cavity equally concerned in the manifestation of a simple mental process, or is the organ of the mind confined to a part or parts of the brain? At an early date it was discovered that the size of the mammalian brain depended to a considerable extent on the size of the body; age and sex, too, were found to influence its weight. The weight of the brain was found to vary widely from individual to individual without any evident relationship to mental ability, so that most scientific men came to share the opinion of the unscientific, that neither the shape nor the size of the head, the volume or weight of the brain, could provide any but the most uncertain indication of mental status. Those who sought a key in the arrangement and complexity of the convolutions have not been more successful. Yet the belief that there is a close relationship between the relative size of the brain and degree of intelligence cannot be abandoned, for it is founded on a study of comparative anatomy. Amongst primates, for instance, it is found that those members which most nearly approach man in size and complexity of brain also most closely resemble him in their mental processes. It is probable, as suggested by Prof. Ray Lankester (NATURE, p. 624, April 26, 1900), that the increase in brain-weight is correlated with the substitution of voluntary or conscious for reflex, instinctive or automatic mental processes, or, in other words, the increase of brain-weight which is seen in the highest primates is the substratum of that mental quality which he has named "educability"; there is also the widespread belief that eminent men have relatively large heads. An examination of the heads of sixty distinguished men led Dr. Beddoe to the conclusion that "Intellectual distinction is generally the concomitant of largeness of brain, though there are numerous exceptions" (*Journ. of the Anthropological Institute*, p. 277, 1904). The method by which Dr. Beddoe sought to establish a correlationship between intelligence and skull capacity is regarded by Lewenz and Pearson as "quite fallacious. To begin with he selects a formula—by guesswork—which is theoretically incorrect" (*Biometrika*, p. 392, vol. iii., 1904). To sum up, anthropologists have not been able to establish, by the methods commonly in use, that there is any direct connection between the size of brain and special manifestations of human intelligence.

Turning now to the biometricians, their conclusions have the advantage of being founded on extensive collections of data, and reached by methods which are mathematically sound. In the number of *Biometrika* cited at the commencement of this article, Dr. Raymond Pearl gives the results of a biometrical analysis of 2100 adult male and 1034 adult female brain-weights, belonging to five races, Swedish, Bavarian, Hessian, Bohemian, and English. Although the matter was only a side-issue in his investigation, he sums up his conclusion as to the correlationship between brain-weight and intelligence thus:—"There is no evidence that brain-weight is sensibly correlated with intellectual ability. The limits of this correlation have been shown to be not closer than 0 and ±0·6." Here are the conclusions of other biometricians:—"There is no marked correlation between skull capacity and intellectual power" (Dr. Alice Lee). "We find the correlation sensible but so small that it is impossible to base any prediction from the size of the head as to general intelligence" (Lee, Lewenz, and Pearson, quoted from *Biometrika*, p. 392, vol. iii., 1904). There are certain circumstances, too, which must be taken into account. From about the age of twenty onwards the weight of the brain gradually decreases, a diminution which is not, as a rule, accompanied by a decrease of intelligence. Nor does the mean brain-weight of a race correspond to the mean intelligence of that race. Of the five races investigated by biometricians, the English have the smallest mean brain-weight. The mean of the adult Englishman is 27 grams less than the Bavarian mean, 57 grams less than the Hessian mean, 65 grams less than the Swedish mean, and 120 grams less than the Bohemian mean. "The order of racial average brain-weight is very far from the order of average racial intelligence. Nor is the order bettered if we allow in any manner for stature" (Blakeman). On the data at present available, one must come to the conclusion, apparently anomalous, that a big brain, so far as the manifestation of intelligence is concerned, has very little if any advantage over a small brain. The explanation of that anomaly lies with the experimental physiologist and psychologist. Meanwhile it is well to remember that under the title of brain-weight is grouped a complex of organs which are diverse in structure and in function.

If there is so little correspondence between brain-weight and brain-function the apparent preponderance of the man's over the woman's brain in weight and size loses much of its significance. It is now possible, thanks to the labours of the biometricians, to speak with a degree of accuracy and assurance as to the extent of that preponderance. The sexual difference in mean brain-weight is least among the English; the preponderance of the male in England is 100 grams (Pearson, from combined data) or 103 grams (Blakeman, from Gladstone's data); in Hesse 132 grams, in Bavaria 142 grams, in Bohemia 144 grams, in Sweden 147 grams, and in France 181 grams. In round numbers, the male preponderance is from 8 per cent. to 13 per cent. Amongst gorillas the male preponderance is 17 per cent., amongst orangs 13 per cent., amongst chimpanzees 6 per cent., and amongst gibbons 8 per cent., so that the human sexual differentiation is approximately an average amount for a higher primate. How far is the male preponderance due to greater body size? The conclusions reached by biometricians are the following:—"Differences in stature and age account for less than one-third of the observed sex-difference in brain-weight" (Raymond Pearl). "On the whole, as far as present evidence goes, we can safely conclude that there is no sensible *relative* difference in the brain-weights of man and woman, the absolute differences observed are quite compatible with the differences which result from the relative sizes of the two sexes. . . . While our results thus apparently contradict those of Pearl on p. 51 of this Journal (*Biometrika*, vol. iv., 1905) the contradiction is only on the surface, for we have been able to use a far more complete system of physical measurements" (Blakeman, Lee, and Pearson). Yet if the writer has rightly grasped the

[1] *Biometrika*, vol. iv., parts i. ii., June, 1905, (1) "Variation and Correlation in Brain-weight," by Dr. Raymond Pearl (with twenty-three diagrams in the text); (2) "A Study of the Relations of the Brain to the Size of the Head," by Dr. Reginald J. Gladstone (with plates ii., iii., and five figures in the text); (3) "On the Biometric Constants of English Brain-weights," by Mr J. Blakeman, assisted by Miss Alice Lee and Prof. Karl Pearson, F.R.S. (with six figures in the text).

methods used, the difference between the results is due to the fact that in his calculations Pearl took into consideration merely age and stature, while the second group of workers added a third, namely, the diametrical product—a quantity which roughly represents the size of the head. To the writer, who is a professed anatomist but not an expert mathematician, it seems that one must infer from these results that nearly two-thirds of the preponderance of the male brain is correlated with the greater size of the male head, while less than one-third is correlated with the greater size of the male body, using stature as a criterion of size. Clearly, if the writer's interpretation is correct, the cause of the relatively greater weight of the male brain is still to seek, for it will be readily granted that a greater brain must be correlated with a greater size of skull. The writer is prepared to believe that the relatively greater weight of the male brain is not only correlated with, but actually dependent on, the physically greater development of the male body, for amongst the various genera of anthropoids the sexual difference in brain-weight corresponds very closely to the sexual differentiation in body size.

To what extent, then, is the weight or size of the brain influenced by the bulk of the body as measured by stature or weight? Broca *was of opinion* that each addition of 10 cm. to the stature was accompanied by an addition of 5 grams to the weight of the brain; Marshall estimated the amount at 2·4 grams.[1] "In the Swedish males, an increase of 10 cm. in stature connotes an increase in brain-weight of 28·59 grams" (Raymond Pearl); the corresponding amount in English males is estimated by Blakeman at 38·69 grams. Dr. Pearl states that the addition of 16·5 kilos. to the body-weight has the same connotation as the addition of 10 cm. to stature. In biometrical terms, the regression is linear. Such is the conclusion which must be drawn from the human data at present available; but one may legitimately infer from the limited data provided by comparative anatomists[2] that it will ultimately be found that equal additions to the bulk of the body are attended, not by equal increments to the brain-weight, but that each successive addition to the body-weight is attended by a relatively smaller increase in the brain-weight. Manouvrier found that in passing from small to medium-sized dogs the addition of each kilogram to the body-weight was attended by the addition of 2·5 grams to the brain-weight; the increment in passing from medium-sized to large dogs 1·7 grams, and from large to very large dogs 0·7 gram. Marshall concluded from Boyd's data that a somewhat similar relationship exists between the body- and brain-weight in man. Gladstone has arranged measurements made on the heads of 363 Englishmen, belonging to all classes, in four groups, according to stature, and has given the mean diametrical product for each group. The diametrical product, as Mr. Blakeman demonstrates, gives only an approximate indication of the weight of the brain; but, allowing for that, it is still remarkable that the addition to the diametrical product steadily decreases as one passes from the lower to the higher stature groups. There is also direct evidence in favour of this opinion. Levi has demonstrated that the only cells in the body which show a marked correlation in size with the bulk of the animal are the ganglion nerve cells; but the relationship is such that we must infer that every further increment to the body-weight is attended by a diminished addition to the size of the nerve cells. If the cerebral nerve mass is regarded as the governing system of the body, then one would not expect that each addition to the body-weight would be attended by the same increment to the brain-weight any more than every subsequent million added to the population of a country requires an equal addition to its administrative service.

That there is a diminution in brain-weight in old age has been accepted as a truth for many years, but until now the rate of the diminution, the periods of life at which it occurs, and its exact amount have been undetermined. Pearl found that "after the age 15–20 there is a steady though very gradual diminution in the weight of the brain with advancing age. . . . In the Swedish males, an increase of ten years in age connotes a decrease of 19·39 grams in the brain-weight." In English males, from the data provided by Gladstone, Blakeman found that the brain lost 21·97 grams each decade. Not only does the brain decrease in weight, but the head shrinks in all its diameters—at least in our English "general hospital population." The head shrinks more in height than in length or breadth; the writer has observed that the skull of the cat and the gibbon shrinks in its vertical diameter as the animal becomes aged.

The brain reaches its maximum weight at a remarkably early period. Boyd, Vierordt, Marchand, Ziehen, and Gladstone found that the heaviest brain-weights occur between the ages of fifteen and twenty, but their conclusions rest on a narrow and uncertain basis; there is a remarkable dearth of observation on the weight of the human brain between the fifteenth and twenty-fifth years. During that period the body is increasing in size; Powys found that the maximum stature occurred early in the twenty-eighth year (*Biometrika*, vol. i.); since there is a correlationship between brain- and body-weight, there ought, therefore, to be an increase in the size of the brain so long as the body continues to grow. Clearly Blakeman and his collaborators, when they exclude all subjects under the age of twenty-four, are inclined to believe that the brain reaches its prime at a later period than the material at their disposal showed. They conclude that, so far as the weight of the body organs is concerned, there is apparently not a *period*, but only an *instant* of prime. Not more surprising is the result that the brain shrinkage is gradual; one would have expected a more rapid decrease after the ages at which Huxley proposed man should be pole-axed and Osler suggested the application of chloroform.

Much of the labour of the Pearsonian school was undertaken with the view of obtaining a method by which the size or weight of brain could be calculated with a sufficient degree of accuracy in the living subject. With that end in view, they have worked out on the data provided by Gladstone the correlationship of brain-weight with eight physical characters of the body, and found that the circumference of the head and the *diametrical product* (obtained by multiplying the length, breadth, and height diameters of the head) were those which were most closely correlated with brain-weight. Their prediction formulæ (multiple regression equations) are founded on the diametrical product and circumference, with deductions or additions for stature and age. These formulæ are applied to the head of Jeremy Bentham, to a skull reputed to be Dante's, and to "one of ourselves, P." The reputed Dante is found to have a probable brain-weight which is 80 to 90 grams below the mean of the English "general hospital population" (1328 grams); Bentham, a brain which was only a few

[1] See Keith, "The Growth of Brain in Man and Monkeys" (*Journ. Anat. and Physio.*, vol. xxix., p. 288. 1895).

[2] Eugen Dubois, "Ueber die Abhängigkeit des Hirngewichtes von der Körpergrösse bei den Säugethieren" (*Archiv f. Anthrop.*, Bd. xxv., 1899; *see also* Keith, *loc. cit.*)

grams above the English mean; while "P's brain-weight is essentially mediocre." By the use of these formulæ the brain-weight can be predicted in the living with a probable error of 50 grams. "Nothing better can probably be achieved by introducing further external characters, or by considering regression as curved instead of plane."

Looking widely at the labours of the biometricians on human brain-weights, they appear to the writer, who views them as an anatomist rather than a mathematician, to have accomplished three things:—They have fixed accurately the mean brain-weights for five subraces of Europeans, and shown that mean brain-weight is a racial character; they have estimated by a definite standard the degree to which the brain varies in size and weight according to the individual, the sex, and the race; they have worked out the extent to which various features of the head and body are correlated with the weight of brain, and expressed them in definite and permanent terms. They have laid a sound foundation for future statistical work on this subject, and yet, even at the risk of appearing ungracious, it is the writer's opinion that the full explanation of the relationship which exists between intelligence, brain-weight, and other characters is more likely to be discovered by those who investigate the individual than by those who study the mass.

THE HEAD-HUNTERS OF BORNEO.[1]

WITHOUT making any pretence to being scientific, this plain and unvarnished, but eminently readable, narrative of a lady's experiences among the natives of some of the more remote districts of the interior of Borneo contains a large amount of interesting information with regard to the customs and mode of life of both Dyaks and the less well known Muruts. Mrs. Cator, it appears, accompanied her husband on his official trips into the interior of that wonderful island, and during these underwent experiences and faced difficulties such as few ladies would care to repeat, and which afford incontestable testimony as to her pluck and resolution. Among these experiences it will suffice to refer to the account of her sleeping with her husband in a large shed in company with a long row of savage head-hunters who had never before beheld a white woman, or, for that matter, a white man.

FIG. 1.—Head-hunters at Kaningau. From "Everyday Life among the Head-hunters."

FIG. 2.—Head-hunting Chief and his wife with the bamboo water-cans they always use. From "Everyday Life among the Head-hunters."

It is, indeed, the portion dealing with the Muruts, or head-hunters, of the interior that forms by far the most interesting section of Mrs. Cator's volume, and the one which will appeal most strongly to ethnologists. The Muruts, according to the author, are a dark race compared to other races of the interior, and have certain customs peculiar to themselves, the preparation of a specially deadly form of the celebrated upas poison being one of their attributes. Although the Dyaks, except where under strict European control, are enthusiastic head-hunters, they preserve only the scalp and hair of their victims, scalp after scalp being added to their krisses with great pride. The Muruts, on the other hand, carry off and preserve the whole head as a proof of their prowess, their houses being frequently decorated with these ghastly trophies, which the author saw on more than one occasion suspended above her sleeping-place. "But there is nothing revolting in their head-hunting," writes Mrs. Cator; "they fight fairly. It is their chance of winning renown and showing what they are made of. The only low part of it is that a woman's head, owing to her longer hair, is prized even higher than that of a man; but the whole thing is a thrilling game to them, full of excitement and danger. There is nothing unfair in their warfare; both sides are doing the same, and man after man wins his spurs in feats of pluck and daring."

Despite the truculent character of their head-hunting

[1] "Everyday Life among the Head-hunters; and other Experiences from East to West." By Dorothy Cator. Pp. xiv+212; illustrated. (London: Longmans, Green and Co., 1905.) Price 5s. net.

forays, the Muruts, when not thus engaged, struck the author as being exceedingly gentle and extraordinarily peaceful in their home life, so much so, indeed, that during the whole of her sojourn among them not a single "family jar" was witnessed. Although, like most Malays (in the wider sense of that term), the Muruts are somewhat indolent in their nature, yet they collect considerable quantities of camphor, and grow such agricultural and garden produce as is required for all their wants, inclusive of material for clothes, while they are accomplished hunters and fishermen.

We have directed special attention to the account of the Muruts, as being the most interesting in the volume; but all the chapters, including those relating to the west coast of Africa, are well worthy of perusal, and the book may be heartily commended to all our readers. R. L.

REPORT OF THE GEOLOGICAL SURVEY.[1]

WE are glad to welcome the annual report of the director of the Geological Survey upon the work carried on by his staff and himself during the year 1904. It gives not only an account of the areas surveyed and the maps issued, but affords an insight into the new methods of research rendered possible and necessary by the advance of scientific knowledge. It is clear that, although maps showing the distribution of the rocks over the whole of the British Isles have been published, the survey is by no means complete, nor do we see that it can ever be considered as complete until all the resources of scientific investigation can be pronounced to be at an end. With regard to the maps themselves, much of the earlier work was put upon maps published as far back as 1819. Chemistry and physics, the appliances at the disposal of the petrologist, and the knowledge acquired by the palæontologist are all advancing with rapid strides, and we see on reading such a work as the annual report of the director of the Geological Survey how they are all brought to bear upon the economically important questions of identification of strata and utilisation of the resources buried in the earth.

One cannot often walk over the ground and detect at once what is of value in it, but a knowledge of the association of minerals may tell one that a certain vein may lead to a metalliferous lode. Hard earned experience and a well trained eye recognise a band of rock containing certain varieties of plants or animals. It may be itself of no use commercially, but yet be of the greatest value economically if it has been ascertained that it occurs in constant relation to some other stratum which is of value. Thus we find on p. 5 of the summary that "the search for coal beneath the Triassic rocks of the Midlands which has been going on for many years and is likely to continue, has brought into great prominence the importance of an accurate knowledge of the subdivisions of the upper unproductive measures"; and again, p. 11, "A seam of coking coal has been worked to the south-east of Alton. The depth and other details have not yet been ascertained, but fossils, similar to those got by Mr. Wedd in the brickpits at Bullbridge, Ambergate, have been obtained from the tip heap, and it is hoped that their distinctive character may enable this seam to be traced over a considerable area."

When we bear in mind that the discovery of one good seam of coal would probably repay the country the cost of maintaining the survey for many years, let us hope that it will be one of the last institutions affected by any policy of retrenchment.

The first object in founding the survey, and the school and museum then wisely connected with it, was the promotion of scientific research with a direct aim at economic and practical results, and every page of the report before us tells how admirably this object is being carried out. The surveyors note the occurrence and character of the various building materials met with—the stone, brick, and cement produced in various localities; they record where road metal may be procured and discuss the sources of water supply, a subject which, having regard to its importance, might well have a strong staff told off for its investigation.

We find in the text or in an appendix useful analyses of various rocks and minerals, descriptions of methods of dressing ores, and a discussion of the conditions which affect the search for coal-bearing strata which are covered over by immense deposits of later date and irregular occurrence.

It is clear that no one can tell beforehand what will be directly productive of economic results in such investigations as lie before the geologist, and the country demands the encouragement of scientific research and the pursuit of knowledge even where no one could foresee any practical results. We find that the survey does take cognisance of the physical geography of each district examined, its ancient lines of drainage, its raised beaches, and also investigates many difficult questions of chemical, thermal, and mechanical metamorphism, and the petrology and palæontology of rocks not obviously productive of anything of commercial value. The treatment of all these questions is arranged first of all geographically, so that anyone may turn to the description of his own district, and then stratigraphically, and the names of those who are responsible for the different statements are given in the margin. When we realise that this is the report of one year's work, we may look forward to the development of the summary into valuable treatises of great practical and scientific value.

NOTES.

AT a meeting of the Röntgen Society on Thursday next, January 4, Prof. F. Soddy will deliver the presidential address upon "The Present Position of Radio-activity."

THE death is announced of Mr. F. W. Burbidge, curator of the botanical gardens of Trinity College, Dublin. From a short obituary notice in Wednesday's *Times* we learn that Mr. Burbidge was born in Leicestershire in 1847, and, after studying horticulture at Chiswick and at Kew, afterwards combined a good deal of experience as a practical gardener with some adventurous journeys to Borneo and the East Indies as a collector of birds and orchids. He was appointed in 1879 to be the curator of the gardens at Lansdowne Road, Dublin, which belong to the Board of Trinity College, and are attached to the scientific side of the college. He filled his office with distinguished success, and made many important contributions to the literature of his subject, on which he was a recognised authority. He was a member of the Royal Dublin Society and of the Royal Horticultural Society, and in 1889 the University of Dublin conferred upon him the degree of Master of Arts, *honoris causa*. In addition to many articles in periodicals, Mr. Burbidge was the author of several books upon horticultural subjects.

AT a recent meeting of the Wellington Philosophical Society, as reported in the Wellington *Evening News* of November 4, an important discussion took place with re-

gard to the alleged sheep-killing habit of the New Zealand kea parrot. As is well known, this bird is commonly reported to cause the death of sheep—or to leave them in such a condition that death soon ensues—by pecking a hole in the side, and the alleged habit is accepted as a fact in ornithological and other natural history works. According, however, to investigations undertaken independently by a number of New Zealand gentlemen, the story is without a shadow of foundation. The observers included naturalists and estate agents, as well as others whose judgment must be regarded as equally trustworthy. The kea is a bird of unbounded curiosity, and it is suggested that the myth is probably due to this habit, some observer who had seen a kea inspecting the carcase of a defunct sheep or lamb having very likely jumped to the conclusion that the bird was the active cause of the animal's death. It is concluded that although the legend cannot be said to be completely disproved, yet there is not a scrap of evidence in its favour. Owing to its bad repute, the kea is in imminent danger of extermination.

The ornithology of Oxfordshire, by Mr. Aplin, and notes on fishes taken at Yarmouth, by Mr. A. H. Patterson, are the subjects of the two articles in the December issue of the *Zoologist*. Mention of several birds new to the British list or of very rare occurrence in our islands is made in the notes column, the two new forms being the yellow-breasted bunting, from Norfolk, and the dusky thrush, from Nottinghamshire. A correspondent publishes a photograph of the skeleton of the fore-feet of a polydactyle cat, displaying duplication of the thumb on one side, and triplication on the other. Almost exactly similar conditions obtain in the feet of two such abnormal cats exhibited in the Natural History Museum.

The December number of the *Naturalist* contains new regulations for the local protection of birds promulgated by the county councils of the North, East, and West Ridings of Yorkshire in response to a petition presented by the Naturalists' Union of the county. Among the more noticeable items are the extension of the close time for a previously scheduled list of species, the period now being from the last day of February to September 1; the total prohibition of the killing of a number of species mentioned in a second list for a period of five years; and total protection for a similar period of the eggs of a third list of species. Wild-bird shooting is entirely prohibited on Sundays, while two proclaimed areas are to be protected for a further five years. It is added that, in response to an appeal from the Union, the Bridlington Harbour Commissioners have prohibited the practice of firing at the birds on Bempton and Speeton Cliffs from passing pleasure-steamers.

Museum News (Brooklyn, New York), No. 5, opens with a dissertation on the proper mode of visiting museums, that is, in order to derive some benefit therefrom. Type descriptions of two exhibits are appended, one dealing with the eggs of the brant-goose and the other with the manati. The latter, we should say, is an excellent example of what a museum descriptive label ought *not* to be, for while manatis, dugongs, and rhytinas are all referred to, there is not a word to indicate how they are to be respectively distinguished. A novel practical exhibition—desirable or otherwise—has been added to the Children's Museum in Bedford. In a vessel of water are placed a few coins with an invitation to take one; but the coins remain, for in the water are a couple of charged wires, from which a severe electric shock is received.

Four papers on Cretaceous reptiles are included in the December number of the *American Journal of Science*. The two first of these are devoted to a couple of new representatives of horned dinosaurs (Ceratopsia) from the Laramie beds of Wyoming, discovered by the late Mr. J. B. Hatcher, for one of which the finder proposed the name *Triceratops brevicornis*, while to the second, which lacks the single nasal horn, Mr. R. S. Lull gives the new generic and specific title *Diceratops hatcheri*. A figure of a restored model of the head of the latter shows a creature strangely like a rhinoceros, save for the rudimentary condition of the nasal horn and the presence of a pair of horns above the eyes. We have now evidence of the existence of either one, two, or three functional horns in the Ceratopsia—features correlated by Mr. Lull with differences in the mode of attack of these giant reptiles. The one-horned form is supposed to have attacked in what the author describes as rhinoceros-fashion, *i.e.* with an upward thrust. Mr. Lull, however, appears to be unaware that neither of the Asiatic one-horned rhinoceroses uses its horn for fighting, but relies solely on its tusks! A mounted skeleton of a third species, *Triceratops prorsus*, in the U.S. National Museum, forms the subject of an illustrated paper by Mr. C. Schuchert. The fourth of the aforesaid series of reptilian papers is the first of a series by Mr. G. R. Wieland on Upper Cretaceous turtles, the forms dealt with in this instance being the small but thick-shelled Adocidæ (Adocus and Agomphus). The thickness of the shell may have been correlated with sublittoral habits as a protection against predatory dinosaurs.

The four latest issues of the *Proceedings of the U.S. National Museum* comprise the description by Miss Richardson of a new species of the crustacean genus Livoneca from Panama (No. 1430); an account of the breeding habits and the segmentation of the eggs of the Florida pipe-fish (*Siphostoma floridae*), by Mr. E. W. Gudger (No. 1431); notes on exotic earwigs, with descriptions of new species, by Mr. J. A. G. Rehn (No. 1432); and a list of fishes collected at Shanghai and Hong Kong in 1882–3, by Messrs. Jordan and Seale (No. 1433), containing descriptions of half a dozen species regarded as new to science. In the above-mentioned paper on the Florida pipe-fish, Mr. Gudger gives a detailed summary of the history of our knowledge of the breeding habits of pipe-fishes and their kindred, and then discusses those of the species under consideration. In all these fishes the ripe eggs are transferred from the oviducts of the female to a special brooding-pouch on the under-side of the abdomen of the male. In the case of the Florida species, when the eggs are ready for transference the male and female fishes swim round and round one another for a time, and then intertwine their bodies in the form of a double letter S, with the heads of each turned outwards. In this position the eggs are transferred from the ovary of the female to the pouch of the male, where the two are in contact, about a dozen eggs being received in the pouch, where they are presumably fertilised. The male then performs a series of evolutions for the purpose of "shaking down" the eggs into the end of the pouch, on the completion of which the process of transference is resumed. The eggs, which soon become fixed to the pouch, are hatched in ten days. Full details, with illustrations, are given of the segmentation.

The first appendix to the *Kew Bulletin* for 1906 has put in an early appearance; it contains a list of seeds of hardy herbaceous plants, and of trees and shrubs available for exchange with botanic gardens or regular correspondents of Kew.

It has been recognised that in the case of the wintergreens, species of Pyrola, the seedlings possess some undiscovered peculiarity. In 1882 Kamienski described for the allied genus Monotropa the formation of a thread-like body out of which the flowering shoot arose. Ten years later Prof. J. Velenovsky announced that from the seed of Monesis, or *Pyrola uniflora*, there develops a primary body, a *procaulom*, from which the leafy shoot develops endogenously. Recently he has published an account of the seedlings of *Pyrola secunda* in the *Bulletin international de l'Académie des Sciences de Bohême*, October, in which he confirms his previous conjectures.

Farmers in New Zealand are well instructed by the Department of Agriculture as to the wisdom of exterminating weeds, so that a discussion of the weed habit in plants by Dr. L. Cockayne, published in the *Canterbury Agricultural and Pastoral Association's Journal*, October, has its special interest. On cultivated lands the weeds are mostly aliens, but a number of indigenous weeds are spreading over pasture lands in different parts; they include *manuka* scrub, Leptospermum, cotton wood, *Cassinia leptophylla*, plantains, and species of Acaena that are distributed by means of their hooked burrs. The indigenous grass *Danthonia semiannularis* is a rare instance of an aggressive plant that possesses economic value.

As a point of some importance in connection with the stage at which grasses should be cut for fodder, Mr. H. H. Cousins gives in the *Jamaica Bulletin* (October) the results of chemical analyses made at different times. In the case of hay grass, *Sporobolus indicus*, cut after two weeks' growth, the albuminoids amounted to 10 per cent. of the dry weight, whereas after four weeks they barely reached 6 per cent.; a marked difference was also found in the hay of guinea grass, *Panicum maximum*, cut before flowering or during the fruiting stage. In the same number, in the course of a report on cocoa cultivation, Mr. Cradwick questions whether "fiddler" larvæ can attack undamaged and healthy trees; on this matter there appears to be a difference of opinion.

In St. Lucia, according to the annual report for the year 1904–5 of the botanic and experiment stations, cacao planters are beginning to learn from the successful results shown on the experimental plots that a greatly improved yield can be obtained by systematic manuring and intense cultivation. Among products of secondary importance, the dwarf or Chinese banana, *Musa Cavendishii*, is receiving a trial, and the cultivation of vanilla is recommended. Mr. Hudson, the agricultural instructor, writing on the subject of supports for vanilla plants, selects the Liberian and a wild coffee plant, or the annatto, *Bixa orellana*, as the most suitable.

The annual report for the year 1904–5 of the Board of Agriculture in Jamaica contains an account of numerous experimental plantations at Hope Experiment Station for testing varieties of bananas, plantains, cassava, tannias, citrus fruits, pineapples, and sweet potatoes. Of these crops cassava is of special importance, as it could be cultivated profitably on much land that is now lying waste, if central factories were erected for the purpose of manufacturing starch. In addition to the experimental plots, where sixty varieties of cane are on trial, the sugar industry is likely to benefit greatly by the central laboratory which is to be constructed. This will contain a room fitted up for analytical work, a fermentation laboratory, and an experimental distillery.

It is becoming more and more evident that, even in minor earthquakes, the focus may be much more complex than the simple fissure or cavity accepted by earlier seismologists Dr. C. Davison has familiarised us with twin foci in the small earthquakes of the British Isles, and now we have an account, by Dr. S. Arcidiacono, of Catania, in the *Bolletino della Societa Sismologica Italiana*, of the Sicilian earthquake of June 14, 1904, which, though nowhere more than a feeble shock, showed no less than four separate centres of maximum intensity.

A pamphlet issued by Pre. Raffaello Stiatteri, from the geodynamic observatory of Quarto Castello, near Florence, deals with the determination of the distance of the epicentre of an earthquake from the duration of the preliminary tremors. He finds from his own observations that, for epicentres not more than 2000 km. distant, the distance in kilometres is 5·63 times the duration of the tremors, expressed in seconds. Prof. Omori, working in Japan, deduced a similar formula, but his factor was 6·54 for the same limit of distance. This is attributed, with what seems sound reason, to a difference between the constitution of the earth's crust under central Europe and that under the sea east of Japan; but the possibility is indicated that the difference may be partly attributable to Prof. Omori's instruments being less adapted for picking up the earliest tremors than those built and used by the Abbé Stiatteri since 1902.

At Detroit, Michigan, large deposits of salt underlie the limestone and sandstone at a depth of 1500 feet. Boreholes have been put down through which brine has been pumped; but up to a year ago all attempts to sink shafts to mine the salt have proved failures owing to the sulphur and gases encountered. On February 20 a new shaft was begun, and has been successfully carried to the salt. Illustrations given in the *Engineering and Mining Journal* show that a crib was employed made of 12 by 12-inch timbers bolted together and made absolutely water-tight. This was forced from the top downwards to the salt, Portland cement being used between the crib and the rock. Two powerful ventilating fans were used for driving out the gases; but even then men could only remain in the shaft for a very short time without losing consciousness.

The last issue of the *Transactions of the Nova Scotian Institute of Science* (vol. xi., part i.), although somewhat belated in publication, records a year's useful scientific work. The most important paper contributed is that by Prof. J. E. Woodman on the geology of the Moose River gold district in Halifax county. It formed part of an investigation into the pre-Carboniferous history of the gold-bearing series. The gold occurs in sedimentary deposits and in veins. In the former it is held chiefly in slates, almost all being in the form of sulphides. In the quartz veins, however, a large proportion is free within the zone of oxidation, and a small amount below it. Detailed descriptions of the veins are given, and the paper is accompanied by eighteen admirable maps and illustrations. Other papers deal with sections and analyses of Nova Scotian coals, by Dr. E. Gilpin; contributions to the study of hydroxylamine and its salts, by Mr. W. H. Ross; and details of about forty fungi determined by Mr. R. R. Gates from the vicinity of Middleton, in Annapolis county.

The Engineering Standards Committee has issued, in the form of a pamphlet of sixty pages, a report on progress of work from January, 1901, to July, 1905. Originally formed with the object of standardising steel sections, its scope has since been greatly enlarged. The subjects dealt

with up to the present time include :—rolled sections; railway and tramway rails; locomotives for Indian railways; pipe flanges; screw threads; pipe threads; limit-gauges; railway rolling-stock material; tire profiles; steel castings and forgings for marine work; Portland cement; cast-iron pipes; generators, motors, and transformers; prime-movers for electrical purposes; physical standards; telegraph and telephone material; electric cables; electric tramway materials; electric automobiles; and electric plant accessories. The report recounts the results of the labours of the committee, and includes a list of the members serving on the thirty-five sectional committees, as well as a list of the publications issued. It is impossible to exaggerate the value of the work done, and the thanks of all engineers are due to the five technical societies who supplied the funds to inaugurate a work of such national importance.

WE learn from the November number of *Das Wetter* that the highest kite ascent on record was made at the aëronautical observatory at Lindenberg (Prussia) on November 25, an altitude of 21,100 feet being attained. In this ascent six kites were attached to each other, with a wire line of nearly sixteen thousand yards in length. The minimum temperature recorded was $-13°$ F.; at starting the reading was 41°. The wind velocity at the surface of the earth was eighteen miles an hour, and at the maximum altitude it reached fifty-six miles an hour. Up to the time of this ascent the highest record by a kite was nearly 1100 feet lower, and was obtained by M. Teisserenc de Bort, from a Danish gun-boat, in the Baltic.

THE Journal of the Meteorological Society of Japan for October contains an article (in French) on the rainfall of Chemulpo. The Japanese observatory was only established in April, 1904; the observations on which the present paper is based were made by the Corean customs officers during eleven years, 1893–1903. The mean annual rainfall is 38 inches, of which 7·7 inches fell in July; 53 per cent. of the total amount fell in three summer months. The average number of rain-days is 89. The heaviest rainfall during one hour was 0·85 inch, in August, 1901. The average duration of rainfall is about six hours, the longest falls being in springtime.

WE have received from Dr. Hergesell, president of the International Aëronautical Committee, a summary of the ascents made during the four months May to August, in various countries, by kites and balloons. Only the heights reached are quoted—not the meteorological results, which will be published later on. The unmanned balloons obtained several records at heights exceeding 15,000 metres in each of the months :—in May, 18,490 metres, at Munich; in June, 20,620 metres, at Munich; in July, 20,000 metres, at Munich; on August 3, 25,800 metres, at Strassburg; on August 2, 15,230 metres, in the Atlantic, on the Prince of Monaco's yacht. In connection with the solar eclipse, ascents were made on the three days August 29–31. On the day of the eclipse, an altitude of 23,010 metres was reached at Munich. During the month of August several kite ascents were made in the North Sea by Mr. G. C. Simpson, under the auspices of the Royal Meteorological Society, and some valuable results were obtained, both as to temperature and humidity.

LORD BLYTHSWOOD and Mr. H. S. Allen contribute to the *Philosophical Magazine* for October an interesting investigation of Dewar's method of producing high vacua by means of charcoal. It is shown that it is only necessary to increase the size of the charcoal receptacle in order to produce a high degree of exhaustion in a large discharge tube without the use of a pump. The method requires only moderate quantities of liquid air, and is particularly useful when it is desirable to avoid the presence of mercury vapour in the vacuum tube, as in the Geissler tubes used for spectroscopic analysis. A special investigation showed that the rate of absorption of the charcoal at any instant is proportional to the difference between the total amount of air absorbed and the amount which has been absorbed at the instant in question, that is, the rate is in a constant ratio to the quantity of air that will still be taken up by the charcoal. The constant is but little affected by alterations of the pressure under which absorption occurs.

THE residual electromotive force of the carbon arc is the subject of a paper by Mr. G. G. Becknell in the *Physical Review* (vol. xxi., No. 3). The circuit used was so arranged that the dynamo and galvanometer could be alternately joined in series with the arc gap, and it was found that the so-called residual current could be observed for more than ten seconds after the interruption of the arc. From the experiments it is concluded that the current can be attributed neither to a thermoelectric effect in the arc nor to one external to it. A description is given of the means by which the residual electromotive force and current are measured as functions of the time, and from the curves shown it is seen that the fall of the current is much more precipitate than that of the E.M.F., showing that the resistance of the arc increases very rapidly. An explanation is suggested by considering that a stream of corpuscles is freely emitted by both incandescent terminals, but more abundantly from the positive, and that these diffuse across the arc gap until the carbons have so far cooled down that the rate of production of the negative ions by the positive carbon no longer exceeds the rate of their production by the negative carbon.

MESSRS. F. VIEWEG AND SON have just issued a second revised and enlarged edition of Prof. F. Hofmeister's "Leitfaden für den praktisch-chemischen Unterricht der Mediziner," originally published in 1899.

MR. J. A. BARTH, Leipzig, has sent us a part of the second edition of the "Handbuch der Physik" edited by Prof. A. Winkelmann. This part is the first half of the fifth volume of the handbook, and in it Prof. F. Auerbach deals with electricity and magnetism. We await the remainder of the work before a review can be undertaken usefully.

MESSRS. A. GALLENKAMP AND CO., LTD., of Sun Street, Finsbury, E.C., are issuing a series of descriptive circulars giving full particulars of special arrangements of physical apparatus which they now make up for fundamental work in experimental science. The forms of apparatus have been carefully selected so that accurate results may be obtained by experiments with them.

NEW editions of parts of two valuable works on physics have lately been published by Messrs. F. Vieweg and Son, Brunswick. One is the first part of the first volume of the tenth enlarged and revised edition of Müller-Pouillet's "Lehrbuch der Physik und Meteorologie," edited by Prof. L. Pfaundler in cooperation with several other eminent German physicists and meteorologists. This part, by Prof. Pfaundler, contains the general introduction on the properties of matter, while the remainder is devoted to mechanics. The work will be completed in four volumes. The second part of the first volume of the seventh edition of Dr. J. Frick's "Physicalische Technik" has also been received. This work will be completed in two volumes, and notices of it and of the above mentioned treatise are best deferred until all the parts have come to hand.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c*.—The results of numerous observations of comet 1905*c* (Giacobini) are published in No. 4058 of the *Astronomische Nachrichten*. Observing at Bamberg on December 10, Prof. Hartwig recorded the magnitude of this object as 10·0 and its diameter as 2′.

The following is taken from an ephemeris published by Herr E. Strömgren in No. 4060 of the *Astronomische Nachrichten* :—

1905–06	α (true) h. m. s.	δ (true) ° ′	log γ	log Δ	Brightness
Dec. 28	16 31 10	+ 5 54·2	9·8601	0·0312	5·16
„ 30	16 46 19	+ 3 45·6			
Jan. 1	17 2 3	+ 1 28·6	9·7908	0·0192	7·51
„ 3	17 18 25	− 0 56·7			
„ 5	17 35 24	− 3 29·7	9·7020	0·0148	11·54

Writing in the *Daily Graphic*, Mr. Denning states that the comet is rapidly becoming brighter, and should become visible to the naked eye early next month. On January 6 the comet will be about fourteen times as bright as when discovered.

ECLIPSE SPECTRA.—At the meeting of the Paris Academy of Sciences held on December 11, M. Salet submitted further, and more detailed, results of the discussion of the spectrograms obtained by him during the recent eclipse of the sun.

Two spectroscopes were employed, the one arranged for photographing the visual part of the spectrum, the other, made up of quartz and Iceland-spar optical parts, for photographing the ultra-violet end.

The slits of the spectroscopes were adjusted so that they bisected the solar images produced by two heliostats and collimators. On the one side of the sun the slit cut through an important group of prominences, and the resulting spectrum shows a number of lines, including those due to H, Ca, coronium, and He, and a line at λ 4025 to which no origin has as yet been assigned. On the other limb of the sun the spectrum shows only the lines due to coronium and the H and K (calcium) lines.

Of all the lines found, M. Salet believes that only the coronium line is truly coronal; this extends to about 4′ above the sun's limb, but does not descend to it, whilst the lines of other elements are strongest next to the limb, and are much shorter than the coronal line.

Twenty-two lines have been measured in the ultra-violet spectrum obtained—which extends to λ 308, and is very rich in bright lines—and of these eight are coincident with strong titanium lines in the ordinary solar spectrum (*Comptes rendus*, No. 24).

IONISATION OF THE ATMOSPHERE DURING TOTAL SOLAR ECLIPSE.—The results of the researches on the ionisation of the atmosphere during the eclipse of August 30, which were obtained by M. Charles Nordmann at Philippeville, are published in No. 23 (December 4) of the *Comptes rendus*.

Until about forty-five minutes after the first contact, the curve registered by the ionograph was of the regularly increasing type, such as was obtained on every day when the sky was clear. But at that time an unusual progressive recession took place, culminating in a sharply marked minimum forty minutes after totality, and this was followed by a gradual increase in the ionisation until, at about twenty minutes after the last contact, the curve assumed its normal height.

It thus appears from this research that the solar radiation is one of the factors on which the ionisation of the atmosphere depends, a result which accords with the hypotheses formulated by Lenard, Elster and Geitel.

The amount of the "lag" of the ionisation curve behind the related eclipse phenomena is also in accordance with theory.

MEASURES OF DOUBLE STARS.—The Greenwich results of micrometer measures of double stars during the year 1904 are published in No. 1, vol. lxvi., of the *Monthly Notices*. The observers were Messrs. Lewis, Furner, and Bowyer, and the observations were made with the 28-inch refractor (28 feet focal length), a power of 670 being generally employed. About 430 stars were measured, some of them on several nights, and the table given shows the coordinates (1900), the position angle, the distance, the magnitude, and the epoch of the observation of each pair.

GRAPHICAL METHOD FOR FINDING THE TIME OF MOONRISE.—In No. 10, vol. xiii., of *Popular Astronomy*, Fr. W. F. Rigge, S.J., of Creighton University (Nebraska), gives and explains a set of curves which may be used for finding the times of moonrise and moonset, on any future date, employing a graphical method which he believes has not been previously published. Three curves are necessary, one to determine the time of the moon's meridian passage, the second to give its hour-angle, and the third to obtain the correction to the rising and setting, due to the moon's motion in right ascension.

The correct result is easily obtained to within an accuracy of one minute, and the author states that he is able to compute the times of both rising and setting, for a whole month, in less than an hour.

NEW BUILDINGS OF THE GLASGOW AND WEST OF SCOTLAND TECHNICAL COLLEGE.

THE first section of the new buildings of the Glasgow and West of Scotland Technical College was formally opened on Thursday, December 21, by the Right Hon. John Sinclair, M.P., Secretary for Scotland. The opening ceremony took place in the examination hall, and was attended by a large and representative assembly. The chairman of the governors, Mr. Wm. Robertson Copland, presided, and in introducing Mr. Sinclair gave several details that are of general interest. The part of the building now completed and occupied represented about 70 per cent. of the whole scheme, and even in its uncompleted state was the largest of the kind in Great Britain. The floor area of the completed part extended to more than 187,000 square feet, or about four and one-third acres; the corridors in the building measured more than a mile in length; and there were 828 windows which required one acre and one-third of glass to fill them. The cost of the completed part was 211,743*l*., and was fully met by subscriptions already paid or by sums about to fall in. Although all the principal classes were now accommodated in the new buildings, there were still several industrial classes—for decoration, furniture design, printing, lithographing, and the like—that would have to be conducted in rooms outside the college. It was also pointed out that since the demand for new buildings became clamant about ten years ago, the increase in the number of day and evening students combined had been about 50 per cent.; last session, 1904–5, the day students numbered 530 and the evening students 4490.

The Secretary for Scotland said it was a very high privilege to be associated in any degree with so important a work. Nobody who knew anything of Glasgow or the west of Scotland and looked round that assembly, both on the platform and before him, could fail to recognise that an occasion which brought together the leading men in so many different spheres of activity was an occasion of special importance. That fact had been emphasised by the figures which the chairman had given them in connection with the technical college, and it must be a special gratification to the governors of the college that public appreciation of their work was so evident in the attendance of leading men that afternoon. As he understood it, this great institution was specially fortunate in carrying on an ancient tradition—a tradition dating from Prof. Anderson, a man who seemed to have been curiously modern in some of his ideas; and it must be a source of strength to that institution that it had so venerable a tradition to support and so wide a field of modern activity. No one would dispute henceforth, if they had been inclined to dispute it hitherto, that Glasgow and the west of Scotland generally, in the erection of that great building, in the size and selection of the staff, and in the growing attendance of the students, had shown a lively recognition of the value of such work as was done in that institution. As the chairman had pointed out, the plans of himself and the board of governors had not been fully attained; he

was sure it was the hope of all present that support would soon be forthcoming to enable the plans to be completed. There was another kind of support equally essential for the progress of the institution—the appreciation of its benefits by those who enjoyed them. They had a guarantee for that in the manner in which the management controlled and guided the affairs of the college; for the governors were assisted by committees having a practical knowledge of the different trades affected, committees consisting of employers and employed, of masters and men. He was sure all those who had the privilege of knowing anything, however little, of this institution would have confidence that in the future as in the past it would meet with that public recognition which it so truly deserved. In closing, he declared the new buildings open.

The memorial stone of the new buildings of the Glasgow and West of Scotland Technical College was laid on May 14, 1903, by His Majesty King Edward, and in Nature, vol. lxviii., pp. 63, 64, a notice was given of the ceremony and also a sketch of the history of the college and an outline of the proposed scheme of new buildings. These will ultimately consist of five large wings, two parallel to George Street and three at right angles to them and parallel to Montrose Street; of these all except the principal portion of the front wing to George Street have been completed. The frontage to George Street will be 346 feet long, more than 100 feet in height, and will contain five floors and a semi-basement; the frontage to Montrose Street, 300 feet long, is shown in the annexed photograph. The plan of confining each department to one floor has been followed in nearly every case, and the internal arrangements generally are believed to be well adapted to efficient working. The figures given in vol. lxviii., p. 64, for the space allotted to each principal department represent very closely the dimensions in the completed part, and the equipment already provided has cost about 24,000*l.*; but additions to the buildings and equipment are urgently required, because, large though the premises are, they are inadequate for the accommodation of all the students of the college, and additional premises have still to be rented. G. A. G.

RECENT STUDIES OF PERIODS IN METEOROLOGY.

In *Symons's Meteorological Magazine* for November (No. 478, vol. xl.) Mr. A. P. Jenkin contributes an interesting note on periodicity of rainfall. Dealing with the Greenwich data commencing in 1843, he finds that there is a three-year period of rainfall, which, however, at times suffers reversal. Thus for a series of years we shall have two wet years followed by a dry one, and for a subsequent series two dry years followed by one wet one. Mr. Jenkin finds that this result can be obtained by transforming an actual period of 3·2 years into a period of 3·0 years, reversals taking place at the end of eight periods, and he compares the values thus obtained with the Greenwich rainfall figures. The result is interesting. As regards the origin of this three-year period, he says the "apparent period of three years with reversals is a real period of between *three and four years,* which is just what Sir Norman and Dr. Lockyer have observed in meteorological phenomena in India and other widely separated parts of the earth. . . ."

Mr. Jenkin has apparently not seen the article which appeared in these columns in June last (vol. lxxii. p. 180), in which the relation between British pressure and rainfall changes and the Thames flow was discussed. The short-period British pressure variations (and consequently rainfall, since the latter is inverse to the pressure) were there shown to be intimately associated with the two main world-pressure types of those authors, as the following extract will show:—"During some years the British area is enveloped in the pressure system that extends over the large area in which India is about the centre, while for another series of years it is dominated by the antipodal pressure system of which South America is the middle portion."

"It is possible that it is this alternate reversion from one type to the other that prevents the 3·8-year change of the Indian and Cordoba curves from occurring in the British curves, and substitutes for it *an apparent shorter period of about three years,* which is very noticeable for some series of years in the British curves."

It will thus be seen that Mr. Jenkin has practically arrived independently at a similar conclusion. In the same note Mr. Jenkin deals with the Cape Town rainfall, which, as he says, shows the same result, though the number of periods in a series is six, and the time of reversal does not coincide with that of Greenwich.

In a series of important articles on the forms of cirrus-clouds, the last of which appeared in the *Meteorologische Zeitschrift* for October (vol. xxii., No. 10), Prof. Oslhoff, of Cologne, sums up his observations, extending over twenty years, as follows:—The ordinary origin of different cirrus forms are air currents of various kinds, which either cause existing cloud material to rend itself, or

carry water vapour which is condensed by penetrating colder air strata, and are immediately converted into ice-needles. These forms are also found under the more moderate clouds of the lower strata of the atmosphere, but in coarser form. Cirrus clouds gradually change their form in a period which coincides with that of the sun-spots, and consequently are caused by solar radiation. No kind of cirrus-cloud can be used with certainty as a weather sign. The influence of the sun at the time of sun-spot maximum is unmistakable in the case of clouds of moderate elevation.

In the *Journal and Proceedings of the Royal Society of New South Wales* for 1902 (vol. xxxvi. p. 42) Mr. H. I. Jensen contributed a paper on the possible relation between sun-spot minima and volcanic eruptions. This paper contained the results of an examination of the statistics, from 1780, relating to seismic disturbances and volcanic eruptions, and the conclusion at which the author arrived was that the frequency of both these phenomena varied inversely with the sun-spot curve, or, in other words, the fewer the sun-spots the greater the number of earthquakes and volcanic eruptions. In the volume of the same journal for the year 1904 (vol. xxxviii. p. 40) the author pursues the inquiry further, and, as he says, "I have succeeded in collecting numerous facts which throw further light on the question and strengthen my former conclusions." Later on in the paper the author refers to the letter published in the *Times* (May 19, 1902) by Sir Norman Lockyer, who stated that earthquakes and eruptions were most frequent at sun-spot minima and maxima. In this connection the author writes:—"My view was, and is, that these phenomena are at a maximum when sun-spots are at a minimum, although from my later researches it seems that at sun-spot maxima there sometimes is a violent and spasmodic outburst of volcanic violence."

Part ii. of this second communication deals with the connection between sun-spot and meteorological phenomena. The author here collects and summarises the conclusions of many workers, and adds a list of recent papers dealing with sun-spots, prominences, corona, earth-magnetism, auroræ, and meteorological data discussed in relation to solar changes. The communication concludes with a table of seismic and volcanic disturbances which occurred between April 1, 1902, and December 31, 1903.

In March last Dr. W. N. Shaw read a valuable paper before the Royal Statistical Society entitled "Seasons in the British Isles from 1878," which appeared in vol. lxviii., part ii., of the journal of that society. We have now received a reprint of that paper, and as it contains no less than 97 pages, including a discussion which occupies 6 pages, the reader may conclude that the subject has received very minute consideration. As director of the Meteorological Office, Dr. Shaw has at his command the most complete and homogeneous series of meteorological observations of these islands that exists, and in the present compilation he has so arranged the data that they are in a form at once suitable to anyone who may wish to study the relations of various phenomena with British weather. Like most other regions of the world, the British Isles are subject to wet years, dry years, cold years, and warm years, so that successive seasons differ very considerably from one another. Some of the meteorological statistics are therefore arranged to show at a glance the various characteristics of any year or season of the year. The contents of the reprint before us are not, however, restricted to the statistics of the meteorological data alone. We find that statistics relating to fog days in London, gales on the east coast, sea casualties, storm warnings, first flowering of forest trees, shrubs, herbs, beginning of corn harvest, yield of crops, deaths from various diseases, &c., are carefully correlated with the meteorological data according to each of the four seasons of the year. In the course of this compilation it was found that the relation between the autumn rainfall and the yield of wheat was very close. In fact, dealing with data from the year 1885, the yield was found to be above the average when the previous autumn rainfall was below the average and *vice versâ* (1889 and 1903 excepted). Space does not permit us to deal with this important contribution at greater length, so we must refer those of our readers who are particularly interested in such statistics to the reprint itself.

In a pamphlet entitled "Ueber die wahrscheinlichkeit von periodischen und unperiodischen Schwankungen in dem atlantischen Strome und ihren Beziehungen zu meteorologischen und biologischen Phaenomenen," written by Otto Petterson, we have an interesting and valuable discussion on the correlation of hydrographic, biological, and meteorological data. This pamphlet is an extract from "Gesamtbericht, 1902–4," vol. iii., of the report and *procès-verbaux* of the international committee on the exploration of the sea (August, 1905), with the addition of an interesting introduction in which is briefly and clearly summed up the general hydrographic condition of those particular parts of the ocean referred to in the paper. In dealing with the annual variations it is first pointed out that there exists a temperature change of deep water (250 metres) at Motowskijfjord which reaches a maximum value in about November; this change is brought about by the Atlantic water. Reference is next made to the annual variations of the depths of the sea near the coasts of Holland and Sweden, and here the maximum is again in late autumn, namely, from October to December. It is shown that we are here in presence of a new phenomenon, namely, an annual pulsation of the sea, of which the whole ocean, from the tropics to the polar seas, takes part.

Our attention is then directed to the changes which take place from year to year, and it is shown how similar are the variations of the temperature of the sea on the Norwegian coast and the air temperature in the centre of Sweden. It is pointed out that the annual variation sometimes suffers perturbations, and is at times retarded or accelerated by a month or two; this is accompanied by important climatic and biological changes. The general impression gained is that the maxima and minima of water and air temperatures in the winter months are repeated in alternate years which indicate a two-year period in the hydrographic perturbations. The author then connects up these regular and irregular changes with the fisheries, and concludes that there exists a close connection between hydrographic, meteorological, and biological phenomena which should in future be taken into account.

ANTARCTIC EARTHQUAKES.

THE *Discovery* carried with her to the Antarctic regions one instrument which kept her, to a slight extent, in touch with the outer world. During the long intervals between the visits of the relief ship there was no word of sport or of the strife of party politics which fill so large a space in the daily papers, but from time to time the Milne seismograph told that somewhere there had been a great earthquake, and in some cases could even say approximately where it had taken place. Now, the records are serving another purpose, and the first instalment of their discussion has appeared as a "Preliminary Note on Observations made with a Horizontal Pendulum in the Antarctic Regions," read before the Royal Society by Prof. J. Milne, F.R.S.

In all, some 3000 feet of films, obtained by Mr. Louis Bernacchi, were brought back by the *Discovery*, and, as might be expected, their examination is still incomplete, in spite of the assistance which Prof. Milne acknowledges; yet one result stands out from the wealth of hints and suggestions which crowds the paper, in the discovery of a new submarine earthquake region lying to the south-west of New Zealand, from which came 73 out of the 136 distinct earthquakes recorded. This, however, does not end the matter, for it is found that not a few of these earthquakes were also recorded by the Milne pendulums in England, that is, near the antipodes of the origin, but not by similar instruments at a less distance. The explanation offered may best be illustrated by a simple experiment, which anyone can perform; take a circular tub containing water, dip your hand into the middle and raise it sharply, thus setting up a group of waves which travel outwards from the centre, becoming less and less conspicuous as the circles widen, until they may cease to be visible; presently, however, the reflected waves, con-

verging on the centre, will become visible, and, as the circles narrow, the waves get higher and more conspicuous until the centre is reached again. So the earthquake waves may become too small to be registered as they spread out from the origin, but again affect a seismograph as they converge towards its antipodes. Doubtless it is not only the earthquakes of the newly discovered region in which this takes place, but the present distribution of teleseismographs is not such as will allow of its being established in the case of other earthquake regions.

Apart from these results, which seem well established, there are many suggestions contained in the paper, two at least being important ones. The first of these concerns a peculiarity in the distribution of the stations at which earthquakes are recorded; for instance, those originating in the region to the south-west of New Zealand will be recorded along a band, of about 20° in width, starting in a north-westerly direction, but not at stations lying, nearer the origin, on one side or other of this band. So, too, earthquakes originating off the west coast of South America have been recorded in western Europe and, near their antipodes, in Siberia, but not at stations which we should expect them to affect were they propagated with equal intensity in an opposite direction.

The other suggestion, which may prove of great importance, concerns the diurnal east and west movement of the horizontal pendulum. This only affects pendula which point north and south and swing east and west; it is only noticeable on days when the sun shines, and has been attributed to the action of the sun's rays in heating or drying up the ground on either side of the recording station. These explanations have not proved satisfactory, and it is now suggested that the movement may be due to some other indirect effect of the sun, probably of an electrical nature. The Milne pendulum, with its silk fibre suspension and agate cup bearing, is practically insulated, and Prof. Milne finds that one of his pendula, after being electrically connected to earth, and therefore preserved at the same potential as the outer case and walls of the observatory, does not show the extensive movements it did prior to being earthed. This line of research is being carried forward with the cooperation of Dr. C. G. Knott, of Edinburgh, and we look forward to seeing some interesting results in due course.

We have indicated the most interesting of the results which have come from the seismographic records of the Antarctic Expedition; want of space forbids us to detail the many other suggestions and possibilities set forth by Prof. Milne, but what has been noticed is enough to show the good use that has been made of the record which, taken by itself, has little value, and only becomes important when correlated with those of the thirty-eight other stations where the Milne type of instrument is now installed.

TECHNICAL EDUCATION FOR FISHERMEN.

ABOUT six years ago the Lancashire Sea Fisheries Committee instituted practical classes for the instruction of local fishermen in the natural history of the common marine edible animals. "Technical education" in the strict sense of the word was not the object aimed at. For some time previously the committee had experienced considerable difficulty in enforcing the restrictions on methods of fishing contained in their by-laws on account of the determined opposition of the fishermen, and the object of the classes was rather to remove this opposition by showing the *rationale* of the by-laws, and to create a common ground on which both officers and fishermen could meet. The committee had no funds which they could apply to this work, and the classes were only made possible by the cooperation of the Technical Instruction Committee of the Lancashire County Council, which made an annual grant of 250*l*. to be spent for this purpose.

Practically all this money is expended in providing "fisheries exhibitions" of the value of 5*l*. each. One or more of these is allotted to each fishing centre in the administrative county of Lancaster, and the men selected to attend are chosen in various ways. In some cases they are selected by the fishermen's associations, and in other cases they are chosen by the officers of the committee. The grant of 5*l*. is intended to recompense the fisherman exhibitioner for the loss of his labour during the time he attends the class, and to provide for his expenses during this period.

The first two experimental classes were held at the (then) University College of Liverpool, but subsequently the work was transferred to the Lancashire Fishery Station at Piel, in the Barrow Channel, where tanks and other apparatus for the study of living organisms are provided by the fisheries committee, and where living material can easily be landed by the committee's vessels. The men are brought to Piel and taken away again by the patrol steamer, and lodge in the neighbourhood of the station. Each class consists of fifteen men, the maximum number which can be taught at one time with advantage. Twenty two-hour lessons are given during each course.

The course of instruction was drawn up by Prof. Herdman and Mr. Johnstone, and great care was taken to arrange a logical sequence of lessons. The structure of a typical fish is the first lesson, and this is followed by an account of the life-history of a typical mollusc such as the mussel. A short demonstration of the main chemical and physical processes involved in the respiration of marine animals is then given, and the manner of feeding of two such divergent types as the fish and mussel is then considered, a discussion which naturally leads up to three or more lessons on the nature and occurrence of plankton and on the economic importance of the latter. The remaining lessons deal with the life-histories of other economic marine animals, the cockle and oyster among Mollusca, and the shrimp and crab among the Crustacea. The life-histories of various fishes, such as the flat-fish and skate, are also considered, and the development of the flounder is studied from the process of fertilisation up to the time when the embryo issues from the egg. Although lantern and other demonstrations are given, the instruction is in the main practical in character, each man being provided with a good microscope and a set of dissecting tools.

On the whole the results of the classes have been very satisfactory; the main object, that of bringing about a better understanding between the fishermen and the committee, has been attained, and though there is still considerable opposition on the part of the fishermen towards the by-laws, yet the relations are much less embittered than was formerly the case. Another result of considerable importance has been attained in that the shell-fish transplantation operations carried on at Morecambe (an account of which was given recently in NATURE, August 31, p. 430) have been traced directly to the stimulus afforded by the classes. This work was originated by the Morecambe fishermen themselves, and it was in this district that the fishery classes were most appreciated and supported.

J. J.

LIFE-HISTORY OF THE EMPEROR PENGUIN.[1]

THE emperor is the largest of all the penguins, and is limited strictly to the ice-covered regions of the Antarctic. The interest of its life-history lies chiefly in the fact that its breeding ground was first discovered during the recent expedition made by the *Discovery* into the Antarctic. Its young and its eggs were brought home for the first time when the *Discovery* returned to England in September, 1904.

In reviewing the life of this bird, the difficulties of investigating its breeding habits were explained as the result of certain peculiarities; for example, that of laying the eggs in the middle of the winter darkness; each hen laying a single large egg, which it incubates as it stands in an upright position on sea-ice, keeping the egg from contact with the actual ice by holding it on the *dorsum* of the foot, and allowing a heavily feathered fold of skin to fall over it from the abdomen, thus completely obscuring it from view, and keeping it closely appressed to the abdomen, warm enough to hatch out, probably in some seven weeks. In the coldest month of the whole year,

[1] Abstract of a paper delivered before the Royal Institution by Edward A. Wilson.

viz. August, the chicken is hatched out, and becomes the unwilling recipient of so much attention from its parents, and from such other adults as have no young of their own to attend to, that upwards of 77 per cent. die, and may be picked up frozen on the sea-ice, within the first month or two of their existence. This high death-rate is in a large measure the result of the quarrels of adult birds for possession of a chicken, all having an overpowering desire to brood over something. In many cases the desire leads to brooding over dead chicks until they are actually rotten.

Much was said of the trials that must be endured by the naturalist who wishes to see this bird in its breeding haunts. He must be ready to encounter the lowest temperatures hitherto recorded, under canvas, sleeping three in a bag for what warmth can be procured at 40°, 50°, and 60° below zero Fahrenheit, and for a fortnight or three weeks at a stretch. Much, also, was said of the various sledge expeditions undertaken, after its first discovery by Engineer-Lieutenant Skelton, R.N., for the purpose of fully investigating the emperor penguin rookery at Cape Crozier; of the discovery of the first egg on the sea-ice by Lance-Corporal Blissett, R.M.L.I., and of the exceptional circumstances which, in the following year, enabled the lecturer to bring back to the ship a series of some fourteen eggs and several dozen of the young.

Examples were shown at the close of the lecture, which was further illustrated by a series of lantern slides, made from photographs taken mainly by Mr. Skelton and from drawings by the lecturer of the various stages in growth of the emperor penguin, from infancy to old age.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

IN view of the approaching contest for the representation of the University of London in Parliament, Sir Michael Foster, K.C.B., and Sir Philip Magnus have placed their opinions before members of Convocation of the University.

SIR WILLIAM ANSON has accepted the position of president of the Association of Technical Institutions for next year in succession to Sir Philip Magnus. The annual meeting of the association will be held at the Fishmongers' Hall on January 26 and 27.

THE annual conversazione of the Royal College of Science and Royal School of Mines was held on December 20. All the departments of the college and school were open, and many interesting exhibits were shown in chemistry, physics, mechanics, metallurgy, mining, geology, botany, and zoology, including applied science. The metallurgy section comprised a working exhibition of Japanese smelting methods shown for the first time in Europe. Japanese casting was made during the evening. The programme also included a lecture by Prof. S. H. Cox on "Incidents of a Mining Career."

THE late Mr. John Feeney, by his will dated June 22, 1903, bequeathed sums amounting to 89,000*l.* towards various institutions and objects connected with Birmingham and district. These include 20,000*l.* to the University of Birmingham. This bequest is for the purpose of maintaining a professor, with suitable equipment, lecturing on some one or more scientific subjects directly connected with some one or more of the trades and industries carried on in or near Birmingham. All the bequests are given free of legacy duty, but payment cannot be claimed until the expiration of five years.

THE Board of Education has published the reports, for the year ending March 31, 1905, of fourteen colleges which participated during the year in the annual grant, amounting to 54,000*l.*, made by Parliament for "university colleges in Great Britain," and from the three colleges in Wales which receive a grant of 4000*l.* each. The reports have been compiled, so far as has been found conveniently possible, under the same headings as those adopted in previous years. The distinguishing characteristic of the reports is the elaborate balance sheet with which each is provided showing exactly the revenue available in the case of each college and what precisely is done with it.

A BLUE BOOK (Cd. 2782) has been published giving the statistics of public education in England and Wales for the years 1903–5. The volume of 442 pages is divided into three sections, dealing respectively with elementary schools, State-aided secondary schools, and technical institutions, schools of art and day art classes, evening schools, and similar forms of education. A technical institution within the meaning of the regulations of the Board of Education is an institution giving an organised course of instruction in day classes, including advanced instruction, and provided with a staff and equipment adequate for the purpose. Provision must be made for at least a two years' systematic course in science, or in science and art, either alone or in conjunction with subjects of general, commercial, manual, or technological instruction; and subject to certain temporary provisions, no student may be admitted to the course unless he has passed through, at least, a three years' course of instruction in a school recognised under the regulations of the Board for secondary schools, or unless he is more than sixteen years of age and is qualified from his general education to profit by a course of advanced instruction. These institutions, in fact, afford instruction adapted for the preparation of young men for employment in connection with the trades, manufactures, and commerce of the country. They also provide higher courses of specialised instruction in science in relation to particular industries, likely to be required by students who have already had a good training in pure science. The number of these institutions receiving grants was nineteen in 1903–4. The number of students who attended at all during the year was 2143, and a grant of 5683*l.* was paid on 1056 of these who attended a full course of instruction. In the same year there were 5570 recognised evening schools with 696,882 students in attendance, on whose work a grant of 304,962*l.* was paid.

AT the annual headmasters' conference held at the College of Preceptors, London, on December 21, the subject of the inspection of schools was dealt with very fully, and numerous resolutions were adopted. Dr. Gow, of Westminster, moved a resolution, subsequently carried *nem. con.*, that the conference desires to emphasise the principle that inspection should take into due consideration the aims and circumstances of the school inspected, and regard intellectual methods and results as of greater weight than material equipment and appliances. Dr. Gow is reported by the Press to have said "there is a general opinion on the part of the public, which is shared by many teachers of science, that great expenditure is necessary for effective scientific teaching, and that schools are invited to compete with one another in mere expenditure. This competition is bad for the schools, for the teachers, and for the boys." It may be contended, he continued, that the better the teacher the more apparatus he wants, but Dr. Gow admitted that his own experience is the contrary of this. "No contention can be more absurd," he concluded by saying, "than that science teaching differs from any other because the science teacher does not teach by authority; it is, as a fact, conducted quite as much on authority as classical teaching, or divinity, or any other subject. The experiments are merely illustrations." The headmaster of Westminster has apparently been unfortunate in his experience of science teaching. Every man of science agrees with him that for the effective teaching of the broad principles of science the simplest apparatus, if of the right kind, is sufficient. This competition among schools to provide the most luxurious laboratories and lavishly stocked lecture-rooms, if it exists, is at least a very modern growth, and should, as Dr. Gow maintains, be discouraged. But at the same time a sensibly designed science workshop with simple fittings and an adequate supply of ordinary apparatus is an absolute necessity for every efficient school. It is difficult to understand what Dr. Gow means when he maintains that science teaching is as much based on authority as the teaching of classics or divinity. There is a confusion of thought here. Reasonable science teaching, with which Dr. Gow seems unfamiliar, insists that the pupil shall believe only because experimental results leave no other alternative, and not because a teacher or a text-book makes a statement. If in any school experiments are used only as illustrations the methods of science

are not followed, and the work is not what men of science desire to encourage. It is satisfactory to know that at least in a large number of our secondary schools the science periods are made the means of inculcating habits of careful observation, persistent verification, and truthful reasoning.

SOCIETIES AND ACADEMIES.

London.

Royal Society, November 23.—"On the Effects of Alkalies and Acids, and of Alkaline and Acid Salts, upon Growth and Cell Division in the Fertilised Eggs of *Echinus esculentus*.—A Study in Relationship to the Causation of Malignant Disease." By Prof. B. **Moore,** Dr. Herbert E. **Roaf,** and E. **Whitley.** Communicated by Prof. W. A. Herdman, F.R.S.

The attention of the authors was attracted to the study of the effects of small variations in reaction upon the growth of cells from the biochemical point of view, as a result of the observation that in malignant disease no hydrochloric acid is in general secreted by the gastric glands, no matter where the malignant growth is situated, which pointed to an increased alkalinity of the plasma.

In the course of investigations upon the rate of growth of the cell, when microscopic examination was made of the cells in the fresh condition, the authors were struck by the marked irregularities in size and shape of the developing cells in alkaline media, illustrated by cells in fresh solution developing in sea-water, to which di-sodium phosphate has been added, and also by marked tendencies to nuclear proliferation.

This led secondarily to a cytological investigation of the cells when fixed and stained to show nuclear division, as a result of which the authors have found the irregular forms of mitosis described in the paper. These atypical divisions, which have been produced by variations in the medium similar to those which occur in the blood in cases of malignant disease, closely resemble the pathological divisions seen in the growths of malignant disease.

The results of the experiments and their relationship to the processes in malignant growths may be summarised as follows:—

(1) In nearly all cases of malignant disease the secretion of hydrochloric acid by the gastric glands is stopped or greatly reduced, and this effect is not due to local conditions in the stomach, since it occurs wherever the growth is situated, but is due to a change in the distribution of salts in the plasma whereby the alkalinity is increased or the concentration in hydrogen ions diminished.

(2) Addition of *small* amounts of alkalies or alkaline salts, such as di-sodium phosphate, to the medium in which cells are growing and dividing causes at first an increase in rate of growth and division, but as the amount is increased there appears a marked tendency to irregularity in size and shape of the resulting cells. Nuclear division becomes in advance of cytoplasmic division, so that the cells become multi-nucleated. As the alkali is further increased, both cell division and nuclear division are stopped.

(3) Accompanying the increased stimulus to nuclear division given by the dilute alkali, there are seen many of the atypical forms of mitosis described in malignant growths. The variations from the normal illustrated in the drawings are:—(1) multiple nuclei in the same cell in active division; (2) multipolar mitosis, occurring both in the single cell stage, and later in the development of the organism; (3) asymmetrical mitosis, leading to unequal distribution of chromosomes to the two daughter cells; (4) reduction in length of the chromosomes as the strength of alkali is increased until the chromosomes appear as rounded dots, and accompanying the reduction in length there is also a reduction in number to about one-half the normal; (5) in certain cases the chromatin becomes arranged in circles, each of which shows a number of thickenings. The circles are arranged in groups in the cell, and appear to represent a stage in the anaphase, the groups being placed at about the usual distance apart of the centrosomes, and traces of the achromatic fibres being occasionally visible.

"On certain Physical and Chemical Properties of Solutions of Chloroform and other Anæsthetics.—A Contribution to the Chemistry of Anæsthesia. (Second Communication.)" By Prof. B. **Moore** and Dr. Herbert E. **Roaf.** Communicated by Prof. C. S. Sherrington, F.R.S.

The experiments recorded in the present communication support the conclusion drawn in a previous paper by the authors that anæsthetics form unstable compounds or aggregates with the proteids of the tissue cells, and that anæsthesia is due to a paralysis of the chemical activities of the protoplasm as a result of the formation of such aggregations.

The comparative experiments with ethereal extracts demonstrate that the action is upon the cell proteids and not upon the lipöids.

The compounds or aggregations so formed are unstable, and remained formed only so long as the pressure of the anæsthetic in the blood is maintained.

The results of the experiments may be summarised as follows:—

(1) The solubility of all anæsthetics experimented with is higher in serum than in water.

(2) At a certain concentration, definite for each anæsthetic, there occur opalescence and commencing precipitation of proteid.

(3) At equal concentration of chloroform in water or saline on the one hand, and serum, hæmoglobin, or the tissues (brain, heart, muscle, and liver) on the other, the vapour-pressure is always higher in the former than in the latter.

(4) The curve connecting vapour-pressure and concentration is, in the case of water and saline, a straight line; while in the case of serum, hæmoglobin, and the tissue proteids it is a curve showing association, especially at the higher concentrations.

(5) Comparative determinations of vapour-pressure and concentration, in serum and brain tissue and in ethereal extracts of these equal in concentration of lipöid, show that the proteid of the tissue combines with the anæsthetic.

(6) Determinations of the effects of addition of chloroform upon the lowering of freezing point confirm the results obtained by the vapour-pressure and solubility determinations.

(7) Determinations of the changes in electrical conductivity caused by addition of chloroform indicate that accompanying the combination of the anæsthetic with the proteid there takes place a splitting off of electrolytes.

(8) When the lipöids, extracted from serum or tissues by ether, are made up into an emulsion with normal saline, many of the lipöids take the form of bi-concave discs.

(9) The lipöid emulsions are very permanent, but separate on the addition of anæsthetics or neutral salts, in similar fashion to colloidal solutions.

"A Note on the Effect of Acid, Alkali, and certain Indicators in Arresting or otherwise Influencing the Development of the Eggs of *Pleuronectes platessa* and *Echinus esculentus*." By E. **Whitley.** Communicated by Prof. W. A. Herdman, F.R.S.

(1) The amount of variation from the normal concentration of hydrogen and hydroxyl ions in sea-water which the eggs of Pleuronectes will tolerate is very small.

(2) A disturbance of the equilibrium towards the acid side is much more fatal than the opposite.

(3) A progressive development of resistance to an unfavourable action of the environment takes place in proportion to the age of the eggs.

(4) Phenolphthalein is deadly to the eggs of *Echinus esculentus*, but harmless to those of Pleuronectes, while dimethyl quickly kills the latter, and appears, if anything, to have a favourable influence upon the development of the former.

Anthropological Institute, December 5.—Prof. W. Gowland, president, in the chair. A Dyak witch doctor's medicine chest: R. **Shelford.** The chest is cylindrical in shape and about a foot high, and contains various charms, including water-worn pebbles, a crystal, used for a kind of crystal gazing, and a few simples which have actual curative properties.—Ruins in Rhodesia: D. Randall

MacIver. Mr. MacIver visited sites at Inyanga, Niekerk, N'Natali, Umtali, Dhlo-Dhlo, Kami, and Zimbabwe, views of all of which were shown. At Inyanga there are countless "pit dwellings," consisting of a pit and passage and hut platforms. The elucidation of the mystery of their use is assisted by a study of the Niekerk ruins, which are the most remarkable in the country. The area of these ruins is not less than fifty square miles, and within this area it is almost impossible to walk more than ten yards without coming upon a wall. The general principle appears to be that each hill constitutes a separate unit complete with its own buildings and divided at the bottom from its neighbour by a boundary wall, which is the first of a series of concentric lines. These lines cannot have been for purposes of irrigation, but must have been entrenchments. They always cease at the crown of the hill, which is covered by a series of buildings, and it is this fact which shows the bearing of these walls in the problem of the pit dwellings. The buildings in the hill are of two types, one divided by successive stages from the pit dwelling and the other the pit dwelling itself. The forts at Niekerk are also generally of similar or derived form to those at Inyanga. Similarly, the more advanced type of buildings found at Umtali or elsewhere are all derivatives of the pit dwelling, and Great Zimbabwe itself falls into line, and was simply a royal kraal. In the whole country there seems to be a regular progression with regard to these buildings, the northern region being the most fortified, and the defensive scheme becoming less rigorous towards the south. As to the buildings of these forts and dwellings, all the implements found are of the type used by the natives of the present day, and as at Niekerk there is no evidence of modern squatting it seems fair to presume that similar implements found elsewhere are also not the results of squatting, but were left by the original builders. As to the date, Mr. MacIver cut sections in the ruins he visited, and at Dhlo-Dhlo he made a most significant and conclusive discovery. A trench was cut below the intact cement floor of a hut, and amongst other objects Mr. MacIver discovered fragments of Nankin china. Consequently, no stone was laid at Dhlo-Dhlo before the time when Nankin china was manufactured and imported from the East; experts fix this date as the sixteenth century A.D. This find conclusively fixes the date, for Dhlo-Dhlo and all the other remains exhibit similar characteristics of building, and it may be taken as proved that the ruins of Rhodesia are mediæval or post-mediæval, that they cannot be possibly placed earlier than the eleventh century (probably the very oldest building was not erected before the fourteenth century), and that they were built by a native African race not differing to any great degree from the modern natives.

Entomological Society, December 6.—Mr. F. Merrifield, president, in the chair. *Exhibitions.*—A series of varieties of the Mediterranean *Carabus morbillosus*, showing all intergradations from the ordinary *morbillosus*, and presenting a striking case of geographical variability: Dr. K. **Jordan.** Specimens of *Ptinus pusillus*, Stwem., recently discovered in a corn factor's shop at Edmonton: H. St. J. **Donisthorpe.**—A hermaphrodite of the Proctotrupidæ, a sand-wasp without wings captured by Mr. Poole, and the ♂ *Apion semivittatum*, Gyll., taken many years ago by Mr. Walton near the Tivoli Gardens, Margate, together with a ♀ specimen of the same species discovered while sweeping long grass near the Chequers Inn, Deal, on September 26, 1904: A. J. **Chitty.** A ♂ and ♀ example of the Dipteron *Helophilus transfugus*, L., taken from thistle-heads in the fen marshes at Edmonton last July, and a specimen of *Stenopteryx hirundinis*, a parasite on swallows and martins found on Box Hill, Surrey, in August: F. B. **Jennings.**—Specimens of *Odontopera bidentata* ab. *nigra*, the melanic form of which is rapidly increasing in the Wakefield district of south Yorkshire: G. T. **Porritt.**—Specimens of South African Pierine butterflies taken in the dry season this year, further illustrating the diverse forms, and with them, for comparison, specimens taken during the rains: Dr. F. A. **Dixey.** A ♂ and ♀ specimen of *Ornithoptera chimaera*, Rothschild, and some remarkable species of Delias collected recently by Mr. A. S. Meek in the mountain region of British New Guinea: O. E. **Janson.**—Specimen of a Buprestid beetle, *Cyria imperialis*, Don., having, in addition to the normal fore-leg on the left side, two supplementary fore-legs originating from separate coxæ: Commander J. J. Walker, on behalf of Mr. A. M. **Lea.**—♂ and ♀ examples of *Tetropium crawshayi*, Sharp, bred by the Rev. G. A. Crawshay from eggs deposited in July last in the bark of larches at Leighton Buzzard: G. C. **Champion.**—Unique specimen of *Depressaria emeritella*, Stn., from an unknown locality, on which the species was added to the British list many years ago, and a specimen of *Cerostoma asperella*, L., discovered by Mrs. Hutchinson near Leominster on September 21, 1881, and only taken, as regards Britain, in Dorset (formerly), and Herefordshire very rarely: E. R. **Bankes.**—Series of *Tryphaena comes* bred through three generations, and brought together to test the relative proportions of melanic to non-melanic forms and the possible range of variations to be obtained from a single pair of parents: A. **Bacot.** The exhibitor announced that all the results of the second and third generations seemed to be capable of "Mendelian" explanation. (1) Larvæ of *Collyris emarginatus*, Dej., from Borneo, observed with mouth-parts qualified to excavate burrows in wood. (2) Larvæ and pupæ of Mormolyce, together with a specimen of a fungus of Polyporus split open to show the lenticular chamber excavated by the larva, to which access was obtained by so small an orifice that it was surprising that the emerged beetle could squeeze through: R. **Shelford.**—*Papers.*—Some observations by Mr. A. H. Hamm, of the Hope department, Oxford University Museum, tending to confirm the opinion that *Pieris rapae* chooses for prolonged rest a surface on which it will be concealed: E. B. **Poulton.**—On the emergence of *Myrmeleon formicarius*: W. J. **Lucas.** Descriptions of new species of African Halticinæ and Galerucinæ: M. **Jacoby.**—On the ichneumonidous group *Tryphonides schizodonti*, Holmgr., with descriptions of new species: C. **Morley.**

Linnean Society, December 7.—Prof. W. A. Herdman, F.R.S., president, in the chair.—On the ætiology of leprosy: Dr. J. **Hutchinson**, F.R.S. The author adduced much evidence from all parts of the world in support of the fish hypothesis of the cause of leprosy, more especially from South Africa, China, and Norway. In places where the disease is scattered and infrequent there might, he admitted, be some difficulty in tracing the association of cause and effect; but if regard be taken of those only in which excessive prevalence occurs, all hesitancy would disappear. He challenged anyone, not yet convinced, to name any place in the whole world in which the leprosy prevalence exceeded 50 per 10,000 which was not either a fishing-station or notorious for the consumption of bad fish. As instances of places where this enormous prevalence has been recorded, the following were mentioned:—Minicoy (Maldives), Kalagoan (Bengal coast), Fiji, and the Sandwich Islands. By way of affording a standard of comparison, it was added that the prevalence in Ceylon was only 2 per 10,000, and in India as a whole less than 6.

Faraday Society, December 12.—Mr. James Swinburne, vice-president, in the chair. The physics of ore flotation: J. **Swinburne** and Dr. G. **Rudorf.** The flotation of ores to separate them from gangue is carried out by treating them with dilute acid, or acid sodium sulphate, at a temperature short of boiling water. Little bells of CO_2 attach themselves to the ore particles, but not to the gangue, and the ore particles are floated to the surface, where they are skimmed off. The questions are why the sulphides are selected, and why the temperature matters. The authors hold that it is a question of two opposing forces—adhesion between the solids and the liquid which varies with different solids and liquids, and surface tension of the liquid.—The concentration of metalliferous sulphides by flotation: Prof. A. K. **Huntington.** The paper also embodies the author's contribution to the discussion on the previous paper. Experiments are described which prove that the gas causing flotation is CO_2 derived from native carbonates of iron and manganese present in the ore, and not from calcite or from carbonates produced on the surface of the sulphides by weathering. Carbonates which are decomposed by dilute sulphuric acid in the cold do not

give rise to the formation of a scum. Experiments are also described showing that the gas escaping during flotation carries an electrical charge, leaving an opposite charge on the solution. The assumption of Messrs. Swinburne and Rudorf of the presence of an air-film on the surface of the sulphide particles is criticised, and it is shown that the particles are floated perfectly after precautions have been taken to remove any adherent film of gas by exhaustion with acid, washing with alcohol, treatment with air-free distilled water, and exhaustion with the pump.—The ions of pure water: Prof. J. **Walker.** In the discussion on Dr. Lowry's paper on an application to electrolytes of the hydrate theory of solution, Mr. Bousfield directed attention to an apparent discrepancy between the temperature coefficient of the mobility of hydrogen and hydroxide ions on the one hand, and the temperature coefficient of the conductivity of water on the other. The author points out that when the data obtained by Kohlrausch for pure water are employed, and when allowance is made for the temperature coefficient of ionisation, the discrepancy vanishes.

Geological Society, December 12.—Dr. J. E. Marr, F.R.S., president, in the chair.—The physical history of the great Pleistocene lake of Portugal: Prof. E. **Hull.** There is evidence that the general level of the lake-bed was once nearly that of the outer sea, and that the sea-waters gained occasional access to the lake during the earlier stage of its formation. The lake was eventually drained by the channel cut by the Tagus at the harbour of Lisbon, upon the elevation of the land to about its present level.—The geological structure of the Sgùrr of Eigg: Dr. A. **Harker.** The conclusions arrived at bring the rock of the Sgùrr of Eigg into relation with the other British Tertiary pitchstones, which are all intrusive.

MANCHESTER.

Literary and Philosophical Society, November 28.—Sir W. H. Bailey, president, in the chair.—Experiments on the variation of the electrical resistance of osmium with the temperature: H. **Morris-Airey.** The range over which the experiments were conducted extended from the temperature of liquid air up to dull red heat. The results show that the behaviour of osmium, like that of the ordinary metals, can be represented by a parabolic expression.

DUBLIN.

Royal Dublin Society, November 21.—Prof. W. F. Barrett, F.R.S., in the chair.—Energy of secondary radiation: Prof. J. A. **McClelland.** This paper is a continuation of previous papers in which the author studied the secondary radiation of β particles that is emitted by substances when acted upon by the β rays of radium. The relative intensity of the secondary radiation from a large number of elements for the same incident radiation has been previously measured, the results showing that the secondary radiation is always greater the greater the atomic weight. In the present paper the total energy of the secondary radiation from a lead plate is compared with the energy of the primary radiation that produces it, the plate being thick enough to prevent the transmission of any radiation; the ratio is found to be 0·62 for lead, and corresponding numbers are given for other elements, the numbers, of course, diminishing with decreasing atomic weight, the number for carbon being 0·19. From the known value of this ratio we can calculate theoretically what percentage of the energy absorbed by *any element of the plate* is set free again as secondary radiation; the percentage is as high as 94 for lead and 95 for uranium, with smaller values for lower atomic weights, the percentage for carbon being 53. The importance of this large transformation of the energy of the primary radiation into secondary radiation is shown by some examples. The relation between the coefficient of absorption of the β rays and the value it would have if there were no secondary radiation is calculated; for lead one coefficient is about four times the other. Again, when we determine the coefficient of absorption of a radiation by measuring the intensity after passing through successive layers of a substance, we should, on account of secondary effects, get values of the coefficient diminishing with increased thickness traversed, even if the radiation were perfectly homogeneous. For this reason the β rays from radium are not so heterogeneous as they appear to be from observations on absorption. The paper shows how to determine the true coefficient from such observations.—An improved form of entoptoscope for the detection and delineation of cataract, &c.: W. F. **Barrett,** F.R.S. The author exhibited this instrument, and fully described it with the aid of diagrams and lantern slides.

Royal Irish Academy, November 30.—Prof. R. Atkinson, president, in the chair.—Second report on Irish cave explorations: Dr. R. F. **Scharff,** chairman of the committee. Dr. Scharff gave a general survey of the investigation, and mentioned that the report embodied the results of the work carried on in the caves of co. Clare during the years 1903–4 under the direction of Mr. R. J. Ussher. The latter subsequently showed a series of lantern slides giving a narrative of the events. Prof. Cole described the geological features. The caves originated by the solvent action of water on the Carboniferous limestone, and may possibly be pre-Glacial. Mr. Westropp read the portion of the report dealing with the tools and ornaments found, which included chert scrapers, various bone implements, bronze pins, and a beautifully worked bronze buckle, as well as an ancient gold bracelet. Prof. A. F. Dixon dealt with the human remains, while Mr. Newton described the very numerous bird bones, which included those of the crane, now only an extremely rare irregular visitor to the British Isles. The mammalian and other vertebrate and invertebrate animal remains had been determined by Dr. Scharff, who exhibited specimens of the bones and teeth of Irish elk, reindeer, Arctic lemming, Arctic fox, bear, wolf, and Caffer cat, and those of domestic animals, &c., making remarks on their horizontal, vertical, &c., distribution in the caves.—On the former occurrence of the African wild cat (*Felis ocreata*, Gmel.) in Ireland: Dr. R. F. **Scharff.** Remains of the wild cat are abundant in the upper stratum of the Clare caves. Careful measurements show that this cat was not the wild cat of Europe (*Felis catus*), but the African cat (*F. ocreata* = *F. maniculata*), and that the English cave remains of cat are also mostly referable to the latter species.

EDINBURGH.

Royal Society, November 20.—Lord McLaren, vice-president, in the chair.—Some further results obtained with the spectroheliometer: Dr. J. **Halm.** This was a sequel to a previous communication already published in which the main object was to find how Carrington's law of solar rotation varied with the sun-spot cycle. The relative shift of certain solar spectrum lines taken from opposite limbs of the sun was determined by comparing their positions with the positions of neighbouring telluric lines. If, however, instead of the *difference* of the positions of a chosen solar line the *mean* be taken, the true position of the solar line referred to the neighbouring telluric line is obtained as it would be were the sun not subject to rotation. Now, according to Doppler's principle, the relative position of the solar and telluric lines so determined should be affected by (1) the annual motion of the earth as it recedes from and approaches to the sun; (2) the diurnal motion of the earth on its axis; and (3) the swing of the earth about the centre of gravity of the earth and moon during one complete lunation. The amounts of the displacements of the lines in the solar spectrum due to these three motions may be calculated. The monthly motion is too small to be detected with certainty, being of the same order as the errors of observation. The instrument was capable of detecting the others. By calculating the diurnal effect and subtracting it from the observed positions, Dr. Halm obtained a distinct annual periodicity in the measured positions of the chosen line, and the observed variation agreed within the errors of observation with the calculated effect. Similarly, subtraction of the calculated annual effect left the diurnal effect clearly marked

and agreeing also remarkably well with the calculated value. In the observations, however, which had extended over the last four years, there existed undoubted evidence of a shift which could not be explained in terms of any known motions. It would be interesting to see how this shift continued as the sun-spot cycle passed through its approaching maximum. The only suggestion which the author had to offer in explanation was the possible effect of a changing pressure in the sun in the neighbourhood of the material giving the line.—Observations on the normal temperature of the monkey and its diurnal variation, and on the effect of changes in the daily routine on this variation: Drs. Sutherland **Simpson** and J. J. **Galbraith.** The diurnal temperature variation in the monkey had considerable range, being about twice that of man in normal health. The temperature reached its maximum during the day and its minimum at night. When by artificial illumination and darkening of the room day and night were interchanged, and when at the same time the meals were altered appropriately, the temperature variation was found to change also, the maximum always coming during the time of activity. Starvation for three days quite did away with the rhythmic character of the variation.—Notes on the effect of electric oscillations (co-directional and transverse) on the magnetic properties of iron: J. **Russell.** The oscillations were obtained from an induction coil, and their general effect was greatly to increase the induction in moderate fields, and also to increase the hysteresis during a complete cycle. When the cycles were compared between the same limits of induction, the effect of the electric oscillations was to diminish the hysteresis.—Some electrical measurements on metals: Dr. C. E. **Fawsitt.** The aim of the experiments was to measure the electromotive position of two specimens of the same metal, one of which had been rapidly cooled and hardened and the other slowly cooled and annealed. The metals used were silver, gold, and platinum, and in all cases the hardened amorphous form was found to be electropositive to the annealed crystalline form when placed in dilute acid, the potential difference being about 0·013 volt.

New South Wales.

Linnean Society, September 27.—Mr. T. Steel, president, in the chair.—Notes from the Botanic Gardens, Sydney, No. 11: J. H. **Maiden** and E. **Betche.** In addition to several new species and varieties described, the following species are recorded as new for New South Wales:—*Capparis sarmentosa*, A. Cunn., from the Macpherson Range; *Casearia esculenta*, Roxb., from the same locality (the discovery of this species adds another order, Samydaceæ, to the flora of New South Wales); *Pultenaea mollis*, Lindl., from Gilgandra; *Erythroxylon australe*, F.v.M., from the Macpherson Range; *Strychnos psilosperma*, F.v.M., from the same locality; *Marsilea angustifolia*, R.Br., from Gilgunnia.—Notes on the native flora of New South Wales, part iv., the occurrence of *Casuarina stricta*, Ait., on the Narrabeen shales: R. H. **Cambage.** *Casuarina stricta* is one of the sheoaks found chiefly in the southern part of Australia, including Tasmania, and it is also common in the interior of New South Wales. The author recently found it growing on the Narrabeen shale formation at Newport. The shales dip southerly from Narrabeen, and pass under Port Jackson at a depth of nearly 1000 feet, but outcrop again at Otford and Stanwell Park, where *C. stricta* also reappears. The theory is advanced that in late or post-Tertiary time this species flourished on what is now regarded by geologists as the submerged continental shelf, but formerly was a continuation of the present land-surface, extending, perhaps, twenty miles easterly to the 100-fathom line. As the Narrabeen shales in the vicinity of Port Jackson also rise to the eastward, they would probably have formed the surface in places beyond the present shore-line, and it is suggested that *C. stricta* worked its way up from the south, partly along this old land-surface, but, owing to the subsidence, has all been destroyed with the exception of these isolated remnants at Newport, Otford, and Jervis Bay.—Census Muscorum Australiensium: a classified catalogue of the frondose mosses of Australia and Tasmania, collated from available publications and herbaria records: part ii.: Rev. W. W. **Watts** and T. **Whitelegge.** This second part of the census completes the mosses known as acrocarps. About 370 species are listed.

October 25.—Mr. T. Steel, president, in the chair.—The geology of the New Hebrides: D. **Mawson.** The following is a summary of the author's conclusions:—The chain of islands forming the New Hebrides group owes its existence primarily to the development during Miocene times of a fold-ridge apparently continuous with that passing around the north of New Guinea through Sumatra and on to the better known region of the Himalayas and southern Europe. In the New Hebrides the folding period was preceded by local shallow marine conditions and subdued volcanic activity. The folding force would appear to have been exerted from the direction of Fiji against the foreland of New Caledonian crystalline schists and gneisses; a single ridge probably resulted defining the western line of islands where extensive outcrops of Miocene strata are exposed—in Santo, Malekula, and possibly Efate.

CONTENTS.

THURSDAY, JANUARY 4, 1906.

BRITISH PROGRESS IN ENGINEERING.

National Engineering and Trade Lectures. Edited by Ben H. Morgan. Vol. i., *British Progress in Municipal Engineering.* By W. H. Maxwell. Pp. 182. Price 6s. net. Vol. ii., *British Progress in Pumps and Pumping Engines.* By P. R. Björling. Pp. xii+92. Price 6s. net. Vol. iii., *British Progress in Gas Works' Plant and Machinery.* By C. E. Brackenbury, A.M.I.C.E. Pp. xii+105. Price 6s. net (London: Archibald Constable and Co., Ltd., 1905.)

THESE lectures, as they are termed, are stated to be "a project to stimulate and expand British trade in colonial and foreign markets," and their "primary object is to show colonial and foreign buyers what progress Great Britain has made up to the present time in the manufacture of all classes of machinery and goods. Each lecture will emphasise novel points of design and utility, and up-to-date methods of manufacture; and these points will be graphically illustrated by reproductions of photographs and drawings." They are, accordingly, evidently designed to have an advertising and business character, instead of the educational and instructive objects which are generally associated with lectures. Engineering is assigned the first place in the British industries to be dealt with; and the three volumes enumerated above are the first ones published of the engineering series, eleven more of which are stated to be in preparation by experts in the different branches.

The first of these books, relating to municipal engineering, is definitely divided into three lectures, the first commencing with an introductory review of the progress of sanitary science and the work of large British municipalities, and then proceeding to deal with road engineering and maintenance; the second lecture treats of sewerage and main drainage, and sewage and refuse disposal; and the third is devoted to water supply.

Each lecture contains more printed matter than could possibly be read within the usual allotted period of one hour, not allowing for any references to illustrations; whilst, on the other hand, the space given to these lectures is far too limited to enable these very important subjects, with their wide range, to be dealt with except in a very cursory manner. The aim, however, it must be remembered, of these so-called lectures is not to explain the principles and describe the practice of various branches of engineering, but to indicate to persons in the colonies and abroad, by the aid of illustrations and brief descriptions in some cases, what are considered the best materials and the newest and most useful types of machines for carrying out works in these different branches, and the names of the manufacturers in Great Britain who supply them. For this purpose, in addition to the names of manufacturers and companies, appended in many cases to references to municipal works, plant, and materials, in the text, and to the illustrations, a list is supplied at the end of each lecture of the various makers of the plant, machinery, tools, and materials used in the municipal works which it describes, occupying altogether forty-eight pages. A short appendix, also, at the end of the book, gives a very useful list of the literature bearing on municipal engineering, to assist persons desiring fuller information on the subjects referred to.

These lectures are well illustrated by 196 very clear figures and views, consisting of photographic reproductions and drawings, mostly in full-page plates, with a few folding ones; and a fairly full synopsis of each lecture, together with a list of the illustrations at the commencement of the book, is considered to serve the purpose of an index. Valuable particulars about certain important municipal works will be found here and there in the book; but, whereas the two succeeding volumes, on pumps and gas works, are fairly well suited for the business objects of these lectures, owing to their appertaining so closely to mechanical engineering, the scientific, biological, and civil engineering aspects of municipal works have had to be, to a large extent, sacrificed to the main purpose of these publications.

In the second volume of this series, a brief introduction indicates the importance of pumping and hydraulic machinery, and the main points that should be considered in the selection of pumps under different conditions; and the author then proceeds to describe, with the aid of illustrations, the principal types of pumps and pumping engines made by the chief British firms, pointing out the special features to be borne in mind in buying them, and the particular sort of work for which each form of pump is best adapted. Eight distinct classes of pumps are described in separate sections, namely, pumps worked by hand, pumps driven by water-power and wind-power, gas and oil engine, hot-air, and compressed air-pumps, electrically-driven pumps, and steam-pressure pumps; and the different forms of pumps in each class are given with the names of their makers, together with allusions to their merits in special cases, and any deficiencies in respect to certain conditions of work. Electricity is being rapidly extended as a motive power for pumps, especially for underground working in collieries and mines, and where the power has to be transmitted to a considerable distance; and the construction of directly-driven centrifugal pumps, pumps driven by single, double, and treble gearing, and by belt, the "Riedler" pump, and the sinking pump, is briefly explained. The descriptions of steam pumps occupy half the book, dealt with successively under the four types of direct-acting, rotative, pulsating, and rope- and belt-driven pumps. The book is illustrated by ninety-seven views and drawings of pumps, and at the end, after a short list of books on pumps and pumping-engines published in Great Britain, a directory of British manufacturers of these machines is given occupying twenty-one pages. As in the first volume, the table of contents and an unpaged list of plates are the only index provided in this and the succeeding volume; and the illustrated reference to the English De Laval centrifugal pumps

must have been added as an afterthought, as these pumps do not appear in the table of contents or in the list of plates. This volume should prove valuable in guiding persons requiring pumping machinery, both in the choice of the pump best suited to their requirements, and as to the firms from whom they can be purchased.

The third volume deals with the machinery employed in the various processes involved in the manufacture of coal-gas, such as the handling of coal, retorts, stoking, the removal of coke, condensers, exhausters, washer-scrubbers, purifiers, gasholders, and various gas appliances, with the names of the principal makers; but some of the subjects are referred to in a very cursory manner, two pages only being given, for instance, to water-gas plant, and also to the very important economic question of bye-products. The descriptions are illustrated by one hundred and thirteen views of plant and machinery; and following the principle adopted in the earlier volumes, a classified list of British gas-engineering literature is added at the end of the book, and also of British manufacturers of gasworks' plant and machinery, occupying respectively eleven and twenty-eight pages, amounting to two-fifths of the text of the book. The author holds very optimistic views as to the future of the gas industry, which he considers are borne out by the remarkable success of the recent Gas Exhibition at Earl's Court, and which, in spite of frequent gloomy prophecies of the injurious influence on it of the development of electric lighting, has more than doubled itself in the last twenty years.

Everything has been done on the publishers' part to render these volumes attractive, by very well reproduced illustrations, unusually large and wide-spaced print, good paper, neat binding, and a moderate price; and they may reasonably be expected to be very useful, from a commercial point of view, in making the scope and efficiency of British manufactures and machinery more fully known in the colonies and foreign countries, and thereby extending the range of British trade and engineering.

A STANDARD ATLAS OF ENGLAND AND WALES.

The Survey Atlas of England and Wales. A Series of 84 Plates of Maps and Plans, with Descriptive Text, illustrating the Topography, Physiography, Geology, Climate, and the Political and Commercial Features of the Country. Designed by and prepared under the direction of J. G. Bartholomew. (The Edinburgh Geographical Institute, 1903.) Price $2\frac{1}{2}$ guineas.

THIS sumptuous volume, which began to be issued in parts in 1903, is a credit to all concerned with its publication. Mr. Bartholomew and the Royal Geographical Society are to be congratulated on adding a work of great beauty as well as of scientific merit to the resources of all who have to study England and Wales. These are a majority of the thoughtful members of the community, for "know thy country" is a maxim next in importance in the modern world to "know thyself." A work which concentrates in one volume the materials for a close study of its surface anatomy and human settlements and routes, as well as a general survey of its resources and activities, is a precious possession, which will increase in value as years pass, for it is the most condensed, yet clear and precise, summary of certain aspects of the material condition of England and Wales at the beginning of the twentieth century which the future historian will find within reasonable compass. What would present historians not give for similar records of the England of past centuries?

The present work may be divided into four parts:—(1) general geographical maps; (2) detailed topographical maps; (3) town plans; and (4) text and tables.

(1) The general maps are more complete than in any other atlas, although most of them have been published previously in another form. The first plate, the oro-bathymetrical map, is a new one, and contains names for the outstanding features of the land which may be regarded as at least semi-official. They were selected by Dr. Mill and Messrs. Chisholm and Mackinder at the request of the Royal Geographical Society. It is convenient to have such a set of names, and undoubtedly the greater number, even of those which are new or have had an extended significance given to them, will be generally accepted. There are, however, one or two exceptions. The term gap, which has been familiarised to us in recent years, more particularly in American writings, can hardly be applied to the broad lowland between Wales and the Pennines, though it may be used for the valleys of the Tyne and Aire, which afford narrow but easy routes across the Pennines. Norfolk Edge and East Anglian Ridge are other terms which seem to imply more pronounced topographical features than they represent. The Vale of Pickering seems unduly extended into that of York. We fail to discover any very clear rule as to what features should and should not be named. We find the Vale of York, but not the Vale of Trent or Severn; the Vale of Taunton, but not of Pewsey. While it is a pity that something more systematic and complete has not been attempted, some of the names are distinctly happy and will remain.

The geological map is unfortunately on a smaller scale than that in the companion "Atlas of Scotland," and hardly shows sufficient detail unless for the country south of London, which is shown on an inset. A smaller scale map illustrates the distribution of old, young, and coal-bearing rocks and iron centres. It is clear, but coal and iron are shown in greater detail on a map of mineral products which comes later. Maps of vegetation, lands in pasture or in crops, afford material for a long chapter in geography and economics. The next two sheets show maps of monthly and annual rainfall and temperature, driest and wettest months, the annual range of temperature, and the annual temperature not reduced for altitude. The subsequent two sheets depict the railways in black, the spheres of influence of the various companies being shown by different tints. We welcome

an attempt to illustrate the areas tributary to each railway company, which, if properly done, would be a most valuable guide to business men. The present map is hardly successful in showing more than the obvious, and in the crowded area of south Lancashire and the West Riding of Yorkshire, even when shown on a larger scale in an inset, the method adopted does not do justice to some of the lines. No attempt has been made to distinguish areas which are served by more than one railway; nor does the compiler seem to have taken configuration into account in preparing the map. No doubt the details can be worked out on the half-inch maps which come later, but what might have been a very effective and useful map is somewhat spoilt. It resembles a rough railway company diagram rather than the other maps of the atlas.

The density of population maps by Mr. Bosse, in which the uninhabited area is first marked off, are clear, and reveal a multitude of points not indicated on maps which show the density of population by counties. They form a very effective contrast to two maps showing densities of agricultural, of industrial and commercial population by counties, which, however, summarise the more obvious contrasts of density and of distribution. Administrative divisions, political and ecclesiastical, a commercial and a mineral map end the first section of the atlas.

(2) It is scarcely necessary to direct attention to the merits of Bartholomew's half-inch contoured map, which everyone uses who cycles or motors. It is beautifully printed on sixty-seven sections. The contour lines, as on the Ordnance maps, are shown for every 100 feet up to 1000 feet, and for every 250 feet above that. The areas between each consecutive 100 feet up to 400 feet are tinted in shades of lighter and lighter green, between each 200 feet to 1000 feet, and then between each 250 feet, in deepening shades of brown, a purplish tint being used for the bands between 2750 feet and 3000 feet. This is a reasonable compromise, but for students of orographical features a single colour in different shades would give a clearer picture. The great defect of our Ordnance maps is the absence of a closer contour interval, and for the inadequacy of the existing data in exhibiting the characteristics of the relief Mr. Bartholomew cannot be held responsible.

These maps are wonderfully accurate; in some places they are more up to date than the survey sheets. Only here and there have we detected minor errors. The arrangement of the sections in the atlas is confusing. The numbers zigzag in such a way that it is not possible, without turning to the sheet inside or to the key map, to discover whether they run eastwards or westwards. This difficulty might have been avoided by printing a key map beneath the number outside each sheet and shading the area of the section drawn inside.

(3) The town plans call for little comment, except that they should have been on a uniform scale.

(4) The text consists of clear descriptions of the physical features in relation to political and commercial development by Dr. Mill, with one or two slips, and of the geological features by Sir Archibald Geikie; temperature and rainfall tables for more than a hundred stations (the latter, unfortunately, only for a ten years' mean); agricultural, population, ecclesiastical, demographic, political, commercial, industrial, and railway statistics; a list of railways; the etymology of English and Welsh place-names; and an invaluable bibliography of the maps of the country from the earliest times, specially compiled by Mr. Bartholomew.

It will be seen that the atlas deserves its comprehensive title. The time and art required to produce it have been great, and Mr. Bartholomew very properly makes due acknowledgments to his skilled assistants. The execution is admirable, and the work is not merely one of great scientific importance, but also a specimen of cartography worthy of the reputation of the house of Bartholomew.

LEATHER FOR BOOKBINDING.

Report of the Committee on Leather for Bookbinding. Edited for the Society of Arts and the Worshipful Company of Leathersellers by the Right Hon. Viscount Cobham and Sir Henry Trueman Wood. Pp. 120. (London: George Bell and Sons, 1905.) Price 10s. 6*d*.

In recent years there has been considerable dissatisfaction with the quality of leather used for bookbinding; although many old books have their bindings still in good condition, others more recently bound have become dilapidated. In 1899 the School of Arts and Crafts formed a committee for the investigation of the subject, which appealed later to the council of the Society of Arts requesting it to undertake a thorough examination of the whole question, and in February, 1900, the society agreed to appoint a committee for the purpose. The first meeting was held in May, 1900, and two subcommittees were elected from the members; the first, consisting of Mr. Cyril Davenport, of the British Museum Library; Dr. J. Gordon Parker, director of the London Leather Industries' Research Laboratories; Mr. A. Seymour-Jones, leather manufacturer; Mr. W. J. Leighton, bookbinder; and Mr. Douglas Cockerell, bookbinder, was to visit various libraries to ascertain the comparative duration of various leathers used at different periods and preserved under different conditions. The second subcommittee consisted of Dr. J. Gordon Parker, Prof. Henry R. Procter, professor of leather industries at Leeds University, and Mr. A. Seymour-Jones; its duty was to ascertain the cause of any deterioration noticed and to suggest methods for its prevention. Mr. M. C. Lamb, director of the leather dyeing and finishing department of Herold's Institute, was afterwards added to this committee.

The committee reported in June, 1901, and the report was printed in the *Journal* of the Society of July 5. It was considered desirable to reprint the report in a more permanent form, and with the financial assistance of the Leathersellers' Company the present volume has been produced, which contains more detailed accounts of the work of the subcommittees

than were contained in the appendices to the original report.

It was found that all the bindings examined showed evidence of decay, but the books bound during the last 80 or 100 years were in a worse condition than many of those of an earlier date; some recent binding had deteriorated in as short a period as five years. The deterioration became more general in books bound after 1830; some leather seemed to be good until 1860, after which date nearly all leather appeared to get worse.

Besides the quality of the leather, the conditions under which books are kept have a great influence on the durability of the bindings. When ventilation is good and artificial light is not used the books are in a better condition. The products of the combustion of gas do much mischief, especially on the upper shelves of a library, where the temperature is often considerably raised by the heat from the flames. Sad to relate, tobacco smoke is said to be deleterious. Daylight, and especially direct sunlight, has a bad effect on some leathers and also on the colours of the dyes.

The report discusses fully the durability of the different kinds of leathers which have been used for bookbinding and also the construction of bindings; a specification for binding heavy or valuable books and also one for ordinary library binding are given.

The second subcommittee investigated the cause of decay by many experiments. Three different kinds of skins were tanned with eleven different agents, the tanning process being modified in portions of the specimens. Small strips of the leathers were fastened on boards with one half of each strip exposed and then submitted to various actions—direct sunlight, light from a fish-tail gas-burner, light from an incandescent gas-burner and from an incandescent electric lamp, the fumes and heat of burning gas, currents of moist and dry air alternately in a closed vessel kept at a temperature of 60° to 70° F., carbonic acid gas, and sunlight, but protected from air by glass; the results of many of these experiments are shown by excellent coloured plates.

Experiments were made with purchased leathers, most of which were found to contain free sulphuric acid; this acid has been used of recent years for brightening the colour of bark-tanned calf, from which it removes the iron and tan stains, and much improves the appearance of the material. It was found that in every case the presence of sulphuric acid hastened the destruction of the leather by all the agents tried. The sulphuric acid cannot be entirely removed from the leather by washing with water; a piece of leather containing 1 per cent. of sulphuric acid was washed for five days and nights in running water, and was afterwards found to contain one-fifth of the original quantity of acid. It was found, however, that if leather containing sulphuric acid is washed with potassium or sodium lactate or acetate the effects of the sulphuric acid are neutralised.

Sulphuric acid is also introduced into leather by the pickling which is used for preserving skins that are imported from New Zealand and Australia, the process consisting of acting on the skins with a solution of salt and sulphuric acid. Mr. Seymour-Jones has shown that formic acid may be used in the place of sulphuric acid, and is quite as efficacious. Sulphuric acid is employed in the dye bath for the purpose of liberating certain colours; it has been found that in this case also formic acid may be substituted.

Mr. Seymour-Jones has made a number of determinations of the mechanical strength of skins in their original condition, and also after tanning and other processes; it was found that the breaking stress of the leather is always below that of the original skin.

Valuable sections on the preparation of leather suitable for bookbinding, on bookbinding, and on the preservation of books appear in the report. Appendix i. consists of hints to owners and keepers of libraries by the chairman, Lord Cobham. Appendix ii. is on the fading of colour from sumach-tanned leather dyed with coal-tar colours, by Mr. M. C. Lamb, and is illustrated by coloured plates.

The book is excellently printed and illustrated, and inside the cover are specimens of six varieties of leather in their undyed and dyed conditions. The report should be read by all interested in books and libraries.

H. M.

OUR BOOK SHELF.

A Treatise on Ore and Stone Mining. By Sir C. Le Neve Foster. Sixth edition, revised and enlarged by Bennett H. Brough. Pp. xxx+799. (London: Charles Griffin and Co., Ltd., 1905.) Price 34*s*.

THIS book, when it first appeared in 1894, was the first systematic treatise on mining published in England, and was quite up to date; but later editions were not sufficiently revised, and the hand of death put an end to the gifted author's intentions of re-writing the work. The preparation of a new edition could not have been entrusted to more competent hands than those of his old colleague Mr. Bennett H. Brough. The general arrangement of the book is the same as in former editions, except that chapter xiv., "Principles of Employment of Mining Labour," has become chapter xvii.

The revision of the whole work has been very thorough; recent discoveries of important occurrences of minerals and new methods of mining and treating ores have been brought up to date, while other methods, machinery and appliances, which have been superseded during the last few years, are omitted from this edition.

Additions to the work are interspersed throughout, so that it is difficult to make selections. More prominence is given to the important iron-ore deposits of Sweden and Norway, also to those of Spain. The various kinds of steam turbines, which may, under certain conditions, be used to advantage as motors for pumps, are briefly described. A considerable addition has been made to the list of important percussive rock drills now on the market. The Water Leyner rock drill with its water-flushing apparatus, which tends to prevent miners' phthisis, is introduced to the reader, and the recent important investigations of Dr. Haldane and Mr. Thomas into the mortality of Cornish miners receive the attention they deserve.

We find no mention in chapter vii.—"Haulage"—of Koppel's hydroleum steam locomotive, which is in use at some mines in Great Britain and elsewhere for underground haulage, and deserves to be better known. A 10-horse-power locomotive costs 285*l*., and burns on an average $1\frac{1}{2}$ gallons an hour of crude petroleum, which can be bought for 3*d*. a gallon. Acetylene hand lamps (p. 544) are also used at some of the mines in Great Britain, while one mine at least has had its pass-byes illuminated for years by 30-candle-power acetylene burners supplied from a small generating plant.

We would warn the mining student not to make a pilgrimage to the Frongoch Mine, mentioned more than once, as, unfortunately, the whole of the fine electrical and dressing plant has passed under the auctioneer's hammer and been dismantled.

The amount of accurate and up-to-date information contained in this volume is enormous. No mining student at home can afford to neglect it, and it is a library in itself to mining engineers who go abroad.

The Useful Plants of the Island of Guam. By W. E. Safford. Pp. 416. (Washington: Government Printing Office, 1905.)

DURING the last few years there has been a remarkable advance in the application of scientific knowledge to the cultivation of economic products, and as a result there has arisen a demand for authoritative books providing accurate and recent information. The Department of Agriculture in the United States of America has taken the lead with its useful series of bulletins of an eminently practical nature. In addition there is need of handbooks, similar to this volume by Mr. Safford, which give a comprehensive account of the products of a country or colony. Dr. Watt's dictionary of the economic products of India is a monumental compilation dealing with an area that embraces tropical, subtropical, and mountainous regions, and describes not only indigenous products, but another fifty per cent. of introduced plants; in its present form, size and cost preclude its general use, although it is a valuable work of reference.

The island of Guam, about 100 miles in circumference, is the largest of the Ladrone or Marianne Islands, and passed into the possession of the Americans after the late war, while the rest of the islands were sold by Spain to Germany. The author had many opportunities of studying the islanders and different parts of the island, and made excellent use of this advantage, so that his information is the result of personal observation and inquiry. The introduction, forming nearly half the book, contains a general account of the history, physical conditions, vegetation, fauna, and ethnology, while in the second part is given an alphabetical list of plants with vernacular names and descriptions. Mr. Safford formed a very favourable opinion of the islanders. Agriculture is universally pursued, and even the artificers leave their trade from time to time to attend to the *rancho*. Maize is the principal food crop, rice is grown, but not in sufficient quantity to supply the demand, and taro and yams are cultivated as well as tobacco. Coffee is grown round most of the habitations, requiring little attention, and plantains and bread-fruit thrive luxuriously. Although copra provides the only article of export, the number of economic plants that are indigenous or have been introduced is exceedingly large, so that the list of plants and the information provided would be useful in many tropical countries. Of fibre-yielding plants twenty-three are recorded, including pine-apple, ramie, kapok, cocoa-nut, plantain, Manila hemp, Sida and a Pandanus, but the most valued plant is *Hibiscus tiliaceus*, from which the natives make all their cordage and cables. The island will produce plenty of citrus and other fruits, and several farinaceous and oil-yielding plants were observed. The book is lavishly supplied with excellent illustrations and the information is readily obtainable; in fact, the volume supplies a good model for future compilations of a similar nature, the main defect being a somewhat unusual nomenclature, which does not, however, cause any difficulty in the determination of the plants referred to.

The British Journal Photographic Almanac and Photographer's Daily Companion for 1906. Edited by George E. Brown. (London: Henry Greenwood and Co., 1905.) Price 1*s*. net; 1*s*. 6*d*. cloth.

THE present issue of this year-book appears under the direction of a new editor, Mr. G. E. Brown, but the contents in no way suffer from this change. As has always been the case, and still is, this work is a compendium of everything pertaining to photography, and the photographer would be at a loss if he had not the volume near at hand for ready reference. Under the new guidance, the material brought together is all that could be desired, and in order that any particular portion of it can be looked up at once there is a full "contents" and an elaborate index.

Other features of this annual consist in a capital popular account of photographic copyright as it exists to-day, a most interesting and varied "epitome of progress," being a survey, logically classified, of the year's labour in both technical and scientific photography, and articles contributed by leading writers. The directory of photographic societies, formulæ for the principal photographic processes, and other facts have all been secured and brought up to date, rendering the volume indispensable to the busy photographer.

Nature in Eastern Norfolk. By Arthur H. Patterson. Pp. vii+352. (London: Methuen and Co., 1905.) Price 6*s*.

THIS book contains some very pleasant reading, for Mr. Patterson is a born naturalist, and writes with freshness and enthusiasm. Not the least interesting chapter is the autobiographical one, in which the author tells the story of his early passion for natural history, his painful struggles to gratify it, and his later misadventures, with much relish and humour. We gather that he has at last settled down to a homely life in his beloved native town, and hope that he may long continue in it. The second chapter, general observations on the fauna, is also very good reading, and here the human species is well represented by short but vigorous sketches of old punt-gunners and bird-catchers. The rest of the book is occupied with lists of birds, mammals, fishes, &c.; these naturally do not offer much that is new in a district that has been so thoroughly worked as east Norfolk, but they are often enlivened by anecdotes or personal reminiscences. The discovery of the black rat (*Mus rattus*) as a common species in Yarmouth is extremely interesting, and still more so is the occurrence of a few specimens of *M. alexandrinus*, its southern variety. Other contributions of Mr. Patterson to the natural history of the district are to be found in these pages; most of them are already known to members of the Norfolk and Norwich Naturalists' Society.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The British Association and our Colonies.

PROF. MILNE's letter in NATURE of November 23 (p. 77) will be read with pleasure by all scientific people in the colonies. The benefits to be derived from a colonial meeting such as he suggests are many and various, and I have no doubt will receive full consideration should the idea be given effect to.

Here in Africa, one piece of work which the British Association is the natural body to take up is that of the magnetic survey of the whole continent. The great lack of trustworthy data for immense tracts of this continent has been often commented on. When we remember how much of the continent is in British hands, and how the British Association since its inception has steadily helped and encouraged the study of earth magnetism, the fitness of bringing such a proposal before the association is apparent. At such a conference the possibility of a simultaneous magnetic survey of Australia would naturally be considered. Could these two surveys be carried out—even if very incompletely—they, with the surveys at present in progress and with the proposed ocean surveys of the Carnegie Institution, would form an invaluable contribution to our present knowledge of earth magnetism.

Africa has many other problems—educational, explorational, meteorological—the solution of which would be helped were they taken up at such a conference.

Monotremes and Birds.

IN Semon's *Zoologische Forschungsreisen*, Lieferung xxii. (1904), Disselhorst treats of "Die maennlichen Geschlechtsorgane der monotremen und einiger Marsupialen." On p. 123 are two text figures, both copied from Sir Everard Home, *Phil. Trans.*, 1802, plate xii. One represents the male genital apparatus of *Echidna hystrix*, the other, Fig. 1B of the German work, the stretched male organ of the same animal. Now this Fig. B is, in Home's paper, correctly named "penis of the Drake." Needless to say, this Drake's organ does not in the least agree with that of Echidna, as which it is described in the German work, and our author is sorely puzzled about some of the details, *cf.* p. 131. This may well be the case. Errors and blunders have been made ere now, but the serio-comic point is that this Drake figure has, in the process of reproduction, assumed mammalian characters. In the original figure the base is surrounded by well-drawn feathers, and such are mentioned in the explanation of the plate. The thing is also correctly copied by Owen in his article Aves in Todd's "Cyclopædia," further in the "Anatomy of Vertebrates," vol. ii., Fig. 119, and Owen directs attention to an important error committed by Home in his interpretation of the urethra. But in the recent figure, wrongly attributed to Echidna, the feathers have lost their character as such, and have turned into hairy structures! Who has done this? The author or the artist, or have both combined to correct the faulty original? It is such a strikingly pretty figure that it is almost sure to be propagated, perhaps to be used as a proof of the affinity of the oviparous mammals. But a drake is a drake, for all that.

H. GADOW.

University Museum of Zoology, Cambridge, December 20.

Sounding Stones at Ch'üfu, Shantung.

LAST July I happened to pass through Ch'üfu, the birth- and burial-place of Confucius. In "seeing the sights" of the town I found three very fine examples of "sounding stones," or "stone gongs" as they are sometimes called. These particular examples do not seem to be very well known except by Chinese; none of my foreign acquaintances who have been in Ch'üfu had noticed them. Photo. No. 1 shows the tomb of the grandson of Confucius. The cover of the incense dish (on which my servant is resting his hand) is made from stone, but when struck with a stick, or even with the knuckles, it rings as though it were bronze. In fact, my man in the photograph refused to believe that it was anything but painted bronze until I myself assured him to the contrary. Photo. No. 2 shows two pillars (marked with crosses) of the balustrade in front of the principal hall of the great Confucian temple at Ch'üfu. Struck at any point with a piece of wood, they give a distinct musical note.

FIG. 1.—Grave of the grandson of Confucius Cemetery of the K'ung family, Ch'üfu, Shantung.

Inside the temple is a large tablet, about $5 \times 3 \times \frac{1}{2}$ feet, of the same stone. In this case the note produced varies according to the point at which the stone is struck. The stone from which all these bodies is made is a greyish oolitic limestone. I was informed that it came from a quarry at Kwan Ko Shan, about seventeen miles south-east of Ch'üfu. Most of the stone from this place has no musical quality, but from time to time veins of it are found, and when found it is usually abundant. "Stone gongs" of this kind are found in all parts of the country, and some are in the possession of foreigners. So far as I can find out, they all come from this one locality. They have been known for many centuries, and it is recorded that the district from which they come paid its share of a certain special Imperial tax in "sounding stones." I should be pleased if any reader could give the cause of this very remarkable property, and if it is not understood I would gladly give what help I can towards elucidating it. During this journey I was pressed for time, and as my route lay directly east from Ch'üfu I was not able to visit

FIG. 2.—Detail of Confucian Temple, Ch'üfu, Shantung.

the quarry. Should there be any object in doing so, however, I will take the first opportunity of returning and making any observations that I may be asked to make. Such an opportunity may occur at any time, and, in fact, could be easily made to occur, as the journey would only

take four days each way. I am afraid, however, that it might prove very difficult to secure any sample of this stone for transportation to Europe. Alfred Tingle.

Chinanfu, Shantung, China, November 9, 1905.

Auroræ of November 15 and December 12.

Since my communication of December 9 (Nature, December 28), I have learned that the aurora borealis of November 15 was observed here by several persons between 8.30 p.m. and 9.30 p.m., Halifax time. The appearances were similar to those noted in England (Nature, November 23, pp. 79–80), and the rosy-red streamers seem to have attracted special attention.

I am also informed that an aurora was observed here last night (December 12) at 9.30 p.m. with whitish streamers, but lacking the display of colour observed November 15.

It is somewhat noteworthy that the interval November 15 to December 12 covers a period of twenty-seven days—the time required for one complete rotation of the sun.

Beinn Bhreagh, near Baddeck, Nova Scotia, December 13, 1905.

The Principles of Heredity.

I have every reason to be satisfied with the kind and indulgent review (December 7, p. 121) by "A. D. D." of my book "The Principles of Heredity," but there is one sentence of it on which I should like to comment, more particularly as it contains nothing of blame or praise. "A. D. D." writes, "this book . . . is an embodiment of the recognition by medical men that they depend ultimately for a precise knowledge of nature on the professional biologist—who may or may not, at the same time, be a medical man."

But really I do not think that. On the contrary, I believe it is easily capable of demonstration that the information already in the hands of all medical men is incomparably superior, both in precision and volume, to anything ever possessed, or likely to be possessed, by biologists. It has not been utilised, that is all. The blame does not rest wholly with the medical man. His strictly professional curriculum is burdened by a monstrous but necessary load of facts. His one chance of coming in contact with subjects of general interest and of acquiring habits of sustained and accurate thought lies in the purely scientific part of his curriculum. Here his teachers are biologists who, instead of inculcating wide principles of heredity and evolution, add to the load on his memory by supplying irrelevant scraps of information about jelly-fish, earthworms, cockchafers, and the like—irrelevant, for, in the form they are presented, they do not link up with the studies and interests of his future career, and therefore are forgotten as soon as may be. "A. D. D." complains that I do not sufficiently appreciate classical teaching. It may console him to know that my appreciation of a certain class of scientific teaching is just as—well, hearty.

The biologist has surpassed the medical man in the study of great problems only because his attention has been directed to the subject, and because, on the whole, his habits of thought—not information—have been more precise. Had the medical man received the training of the biologist, or the biologist possessed the information common to medical men, the progress of science would have been much more rapid, and few or none of the great biological controversies of the past would have arisen, or at least have endured the interminable time they did; for example, the disputes as to whether natural selection is the cause or the sole cause of evolution, as to whether acquired characters are transmissible, as to whether variations are due to the direct action of the environment, as to whether evolution proceeds on lines of "fluctuating" variations or of discontinuous "mutations," as to the function of sex, and so forth.

Of necessity we—that is, all men—know the human type better than we can possibly know any other. Provided we know what to look for, extreme familiarity enables us to observe the smallest variations. No shepherd knows his flock, no biologist knows animal or plant as the medical man knows his fellow man. The species has diverged into a large number of natural varieties, dwelling under immensely diverse conditions and differing vastly in every peculiarity of body and mind. All these varieties, apparently, are inter-fertile, and almost all of them, in bulk or in isolated cases, have crossed with almost every other variety. Hybrids are being reared every day, and many races are compound hybrids—*e.g.* the Caucasian-Negro-Indian inhabitants of parts of South America. Above all, the species is being stringently selected and is undergoing rapid evolution under the action of disease, an agency which furnishes the most perfect series of experiments in heredity and evolution imaginable. Every race is resistant to every disease strictly in proportion to its past experience of it. Some diseases are short and sharp, others are of long duration. Some are local, others fill the whole system with micro-organisms or bathe the germ-cells with toxins. Many diseases are new to many races; others they have afflicted for thousands of years. If ever acquirements are transmitted, however "faintly and fitfully," it should be in the case of disease. If ever variations, no matter how small, are caused by the direct action of the environment, a race long afflicted should show the trace. If Mendelian phenomena play an important part in nature, we should note them in crossed varieties of men. If evolution proceeds on lines, not of fluctuating variations, but of stable mutations "which only selection can eliminate," then races (*e.g.* British) which have become highly resistant to this or that disease (*e.g.* consumption) should not constantly produce individuals who are as susceptible as members of a race which has undergone no such evolution (*e.g.* Red Indian).

Unless heredity in man differs from heredity in other species, it is very evident that medical men have no need to go to biologists for precise information, but that there is every need that biologists should go to medical men. A vast fund of minutely accurate data, much of which is statistical, is available. To grope in the obscurity that necessarily surrounds the past and the present of wild species or amid the confusion of the unrecorded crosses of domesticated varieties while this fund is untouched may be magnificent, but it is not science.

Southsea, December 11, 1905. G. Archdall Reid.

Dr. Reid takes exception to a passage in my review of his book; in it I state my belief that his book is the embodiment of a certain opinion, but Dr. Reid writes to say that he does not hold this view at all. It is not necessary, nor would it be profitable if it were, to discuss who is right in this matter—he or I—for obviously I am guilty of misrepresenting Dr. Reid's opinion.

But that the medical man is capable of acquiring a precise knowledge of nature independently of the information already gained and the methods employed by the biologist does not seem to me to be by any means certain. Dr. Reid thinks it is, and brings forward as evidence the fact that doctors possess better data for the solution of problems of evolution than ever have been, or can be, possessed by the biologist. Now, even supposing this to be true—which I do not for a moment—it does not seem to me to prove Dr. Reid's point. Either he thinks that the possession of data is tantamount to a precise knowledge of nature, or he does not; if he does, he proves his point by introducing into his syllogism a premiss which I believe to be untrue; if he does not—and I do not believe that he does—he does not prove his point.

But be this as it may, the point that interests me is that the belief that there is no great step between the collection of data and the derivation from them of a precise knowledge of nature is a widespread and, I believe, a profoundly erroneous one; for it seems to me that the possession of data is a small advance towards such a precise knowledge, and that that which hinders the acquisition of natural knowledge is not the slowness with which facts are accumulated, but the paucity of investigators capable of dealing with them properly; and this dearth is due to the infection of the majority of biologists by a disease—a sort of sleeping sickness—which consists in a disinclination to picture to the mind's eye the things represented by the words they use.

Let us proceed to examine Dr. Reid's main thesis—that

the medical man has better material for the study of evolution than any biologist has had or can have, for the reason, says Dr. Reid, that the animal about which we know infinitely more than we do about any other is man himself. And further than this, he maintains that a knowledge of the relation of man to disease has already furnished us with solutions to such problems as that of the inheritance of use and disuse, and others which he names. Now if the reader is familiar with Prof. Ray Lankester's Romanes Lecture, he will immediately see that great caution must be exercised.

Prof. Lankester in this lecture showed that, though man was a part of nature, he had separated himself from nature, and had set up for himself a *regnum hominis*, where, to use Huxley's terms, the cosmic process was replaced by the horticultural. Man had—if we may use a picturesque expression which has no meaning—disobeyed nature's laws, and had become in Prof. Lankester's words "nature's rebel."

Moreover, it was in the very matter of disease, on which Dr. Reid bases so much, that man had become more different from the rest of nature than in any other respect.

Disease has no existence in nature apart from man; the parasite either kills his host or an equilibrium is established between the two and both continue to live together; whereas in man a state of affairs has been evolved which is entirely peculiar to him, namely, disease.

Now I maintain that these considerations should prevent us from being too willing, or even from being willing at all, to argue from the data that medical men possess concerning the human species, and particularly from the data concerning man's relation to disease, to the rest of nature.

I am sometimes asked, "Is the knowledge of heredity which you acquire from your experiments with mice likely to be applicable to man?" In my opinion the question which the pure biologist should seriously consider before he accepts the truth of Dr. Reid's contention is, "Is the knowledge of heredity acquired by observation on man likely to be applicable to mice? Is that knowledge likely to help him towards a closer acquaintance with the fundamental nature of living things?" My answer is, that it may do to a certain degree, but not so surely as will the kind of knowledge acquired by the pure biologist—a knowledge of nature outside the *regnum hominis*.

Biologists are still very anthropomorphic, and medical men still more so. To the pure biologist man is not a more interesting animal than any other; and, in fact, it might be urged with some justice that as "nature's rebel" he is less so. I am well aware that this view will find no favour with Dr. Reid. On the other hand, Dr. Reid's estimate of the value of the breeding-pen, as an instrument for acquiring a knowledge of heredity, is likely to find as little favour with the experimental breeder. Yet who can say that the one has more of truth in his opinion than the other?

Naturally each one thinks that the point of view from which, and the material with which, he works at a problem is the best, but I am willing to concede to Dr. Reid the point that, considered as material for dealing with heredity, men are nearly as good as mice, if he will allow that mice are nearly as good as men. A. D. D.

A Suggested Change in Nomenclature.

In the *Geological Magazine* for October, 1904, I gave the name Barypoda to a new order of Ungulates, including under it Arsinoitherium and its allies. It has just been pointed out to me by Mr. W. K. Gregory, of the American Museum of Natural History, that this name was previously used by Haeckel ("Generelle Morphologie," ii., p. clvii.) for certain groups of extinct marsupials. It is therefore advisable to suggest another name for the new division of the Ungulates, and I propose that Embrithopoda be employed.

In the case of a generic name, it is comparatively easy to determine with reasonable certainty whether it has been previously used or not, but with the names of higher subdivisions this is very difficult, especially when, as in the present case, the term has never passed into current use.

British Museum (Natural History), London, S.W., December 29, 1905.

NOTES ON STONEHENGE.[1]

X.—SACRED FIRES.

THE magnificent collection of facts bearing on this subject which has been brought together by Mr. Frazer in "The Golden Bough" renders it unnecessary for me to deal with the details of this part of my subject at any great length.

We have these records of fires:—

(1) In February, May, August and November of the original May year.

(2) In June and December on the longest and shortest days of the astronomical year (the solstices), concerning which there could not be, and has not been, any such change of date as has occurred in relation to the May year festivals.

(3) A fire at Easter in all probability added not long before or at the introduction of Christianity. I find no traces of a fire festival at the corresponding equinox in September.

We learn from Cormac that the fires were generally double and that cattle were driven between them.

Concerning this question of fire, both Mr. Frazer and the Rev. S. Baring-Gould[2] suggest that we are justified in considering the Christian treatment of the sacred fire as a survival of pagan times. Mr. Baring-Gould writes as follows:—"When Christianity became dominant, it was necessary to dissociate the ideas of the people from the central fire as mixed up with the old gods; at the same time the central fire was an absolute need. Accordingly the Church was converted into the sacred depository of the perpetual fire."

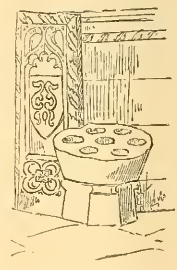

FIG. 24.—Cresset-stone, Lewannick. From Baring-Gould's "Strange Survivals."

He further points out that there still remain in some of our churches (in Cornwall, York, and Dorset) the contrivances—now called cresset-stones used. They are blocks of stone with cups hollowed out. Some are placed in lamp-niches furnished with flues. On these he remarks (p. 122):—

"Now although these lamps and cressets had their religious signification, yet this religious signification was an afterthought. The origin of them lay in the necessity of there being in every place a central light, from which light could at any time be borrowed; and the reason why this central light was put in the church was to dissociate it from the heathen ideas attached formerly to it. As it was, the good people of the Middle Ages were not quite satisfied with the central church fire, and they had recourse in times of emergency to others—and as the Church deemed them—unholy fires. When a plague and murrain appeared among cattle, then they lighted need-fires from two pieces of dry wood, and drove the cattle between the flames, believing that this new flame was wholesome to the purging away of the disease. For kindling the need-fires the employment of flint and steel was forbidden. The fire was only efficacious when extracted in prehistoric fashion, out of wood. The lighting of these need-fires was forbidden by the Church in the eighth century. What shows that this need-fire was distinctly heathen is that in the Church new fire was obtained at Easter annually by striking flint and steel together. It was supposed that the old fire in a

[1] Continued from p. 155.

[2] "Strange Survivals," p. 120 *et seq.*

twelvemonth had got exhausted, or perhaps that all light expired with Christ, and that new fire must be obtained. Accordingly the priest solemnly struck new fire out of flint and steel. But fire from flint and steel was a novelty; and the people, Pagan at heart, had no confidence in it, and in time of adversity went back to the need-fire kindled in the time-honoured way from wood by friction, before this new-fangled way of drawing it out of stone and iron was invented."

The same authority informs us that before Christianity was introduced into Ireland by St. Patrick there was a temple at Tara "where fire burned ever, and was on no account suffered to go out."

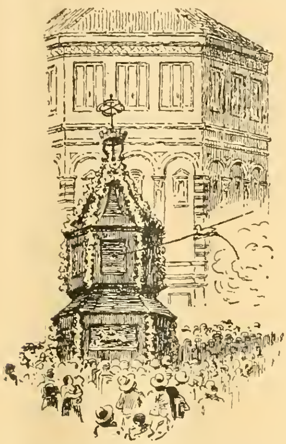

FIG. 25.—The Carro, Florence. From Baring-Gould's "Strange Survivals."

Mr. Frazer,[1] quoting Cerbied, shows that in the ancient religion of Armenia the new fire was kindled at the February festival of the May year, in honour of the fire god Mihr. "A bonfire was made in a public place and lamps kindled at it were kept burning throughout the year in each of the fire-god's temples." This festival now takes place at Candlemas, February 2.

We must assume, then, that the pagan fires were produced by the friction of dry wood, and possibly in connection with an ever-burning fire. In either case the priests officiating at the various circles must have had a place handy where the wood was kept dry or the fire kept burning, and on this ground alone we may again inquire whether such structures as Maeshowe at the Stenness circle, the Fougou at that of the Merry Maidens, and indeed chambered barrows and cairns generally, were not used for these purposes amongst others; whether indeed they were not primarily built for the living and not for the dead, and whether this will explain the finding of traces of fires and of hollowed stones in them, as well as some points in their structure. Mr. MacRitchie[2] has brought together several of these points, among them fireplaces and flues for carrying away smoke.

At both solstices it would appear that a special fire-rite was practised. This consisted of tying straw on a wheel and rolling it when lighted down a hill. There is much evidence for the wheel at the summer but less at the winter solstice; still, we learn from the old Runic *fasti* that a wheel was used to denote the festival of Christmas. With regard to the summer solstice I quote the following from Hazlitt (under John, St.):—

"Durandus, speaking of the rites of the Feast of St. John Baptist, informs us of this curious circumstance, that in some places they roll a wheel about to signify that the sun, then occupying the highest place in the Zodiac, is beginning to descend. 'Rotam quoque hoc die in quibusdam locis volvunt, ad significandum quod Sol altissimum tunc locum in Cœlo occupet, et descendere incipiat in Zodiaco.' Harl. MSS. 2345 (on vellum), Art. 100, is an Account of the rites of St. John Baptist's Eve, in which the wheel is also mentioned. In the amplified account of these ceremonies given by Naogeorgus, we read that this wheel was taken up to the top of a mountain and rolled down thence; and that, as it had previously been covered with straw twisted about it and set on fire, it appeared at a distance as if the sun had been falling from the sky. And he further observes, that the people imagine that all their ill-luck rolls away from them together with this wheel. At Norwich, says a writer in *Current Notes* for March, 1854, the rites of St. John the Baptist were anciently observed, 'when it was the custom to turn or roll a wheel about, in signification of the sun's annual course, or the sun, then occupying the highest place in the Zodiac, was about descending.'"

At Magdalen College, Oxford, the May and June years are clearly differentiated. There is a vocal service at sunrise on May morning, followed by boys blowing horns. At the summer solstice there is a sermon preached during the day in the quadrangle.

One of the most picturesque survivals of this ancient custom takes place at Florence each year at Easter. This is fully described by Baring-Gould. The moment the sacred fire is produced at the high altar a dove (in plaster) carries it along a rope about 200 yards long to a car in the square outside the west door of the cathedral and sets fire to a fuse, thus causing the explosion of fireworks.

The car with its explosives is the survival of the ancient bonfire.

It would appear that the lighting of these fires on a large scale lingered longest in Ireland and Brittany. A correspondent of the *Gentleman's Magazine* (February, 1795) thus describes the Irish Beltane fires in 1782, "the most singular sight in Ireland":—

"Exactly at midnight, the fires began to appear, and taking the advantage of going up to the leads of the house, which had a widely extended view, I saw on a radius of thirty miles, all around, the fires burning on every eminence which the country afforded. I had a farther satisfaction in learning, from undoubted authority, that the people danced round the fires, and at the close went through these fires, and made their sons and daughters, together with their cattle, pass through the fire; and the whole was conducted with religious solemnity."

It will have been observed with reference to these fire festivals that although there were undoubtedly four, in May, August, November, and February, those in May and November were more important than the others. This no doubt arose from the fact that at different times the May and November celebrations were *New Year* festivals. With regard to the New Year in November in Celtic and later times, Rhys writes as follows ("Hibbert Lectures," p. 514):—

"The Celts were in the habit formerly of counting winters, and of giving precedence in their reckoning to night and winter over day and summer (p. 360); I should argue that the last day of the year in the Irish story of Diarmait's death meant the eve of November or All-halloween, the night before the Irish *Samhain*, and known in Welsh as *Nos Galan-gaeaf*, or the Night of the Winter Calends. But there is no occasion to rest on this alone, as we have the evidence of Cormac's Glossary that the month before the beginning of winter was the last month; so that the first day of the first month of winter was also the first day of the year."

That the November bonfire was recognised as

1 "Golden Bough," iii. 248.
2 "The Testimony of Tradition."

heralding the dominion of the gods and spirits of darkness; that the old ideas surrounding Horus and Set in Egypt were not forgotten; is evidenced by the fact that when the fire was extinct the whole company round it would suddenly take to their heels, shouting at the top of their voices:—

Yr hwch du gwta A gipio 'r ola' !	The cropped black sow Seize the hindmost !

A piecing together of the folklore and traditions of different districts suggests that sacrifices were made in connection with the fire festivals, in fact that the fire at one of the critical times of the May year was a sacrificial one.

I will quote two cases given by Gomme[1] for May Day and All Souls' Day respectively:—

"At the village of Holne, situated on one of the spurs of Dartmoor, is a field of about two acres, the property of the parish, and called the Ploy Field. In the centre of this field stands a granite pillar (Menhir) six or seven feet high. On May-morning, before daybreak, the young men of the village used to assemble there, and then proceed to the moor, where they selected a ram lamb, and after running it down, brought it in triumph to the Ploy Field, fastened it to the pillar, cut its throat and then roasted it whole, skin, wool, &c. At midday a struggle took place, at the risk of cut hands, for a slice, it being supposed to confer luck for the ensuing year on the fortunate devourer. As an act of gallantry the young men sometimes fought their way through the crowd to get a slice for the chosen amongst the young women, all of whom, in their best dresses, attended the Ram Feast, as it was called. Dancing, wrestling, and other games, assisted by copious libations of cider during the afternoon, prolonged the festivity till midnight."

In the parish of King's Teignton, Devonshire, "a lamb is drawn about the parish on Whitsun Monday in a cart covered with garlands of lilac, laburnum, and other flowers, when persons are requested to give something towards the animal and attendant expenses; on Tuesday it is then killed and roasted whole in the middle of the village. The lamb is then sold in slices to the poor at a cheap rate."

The popular legend concerning the origin of this custom introduces two important elements a reference to "heathen days" and the title of "sacrifice" ascribed to the killing of the lamb (p. 31).

"At St. Peter's, Athlone, every family of a village on St. Martin's Day kills an animal of some kind or other; those who are rich kill a cow or sheep, others a goose or turkey, while those who are poor kill a hen or cock; with the blood of the animal they sprinkle the threshold and also the four corners of the house, and 'this performance is done to exclude every kind of evil spirit from the dwelling where the sacrifice is made till the return of the same day the following year'" (p. 163).

Other traditions indicate that human sacrifices were in question and that lots were drawn, or some other method of the choice of a victim was adopted. I quote from Hazlitt (i., 44) the following report of the Minister of Callender in 1794:—

"The people of this district have two customs, which are fast wearing out, not only here, but all over the Highlands, and therefore ought to be taken notice of, while they remain. Upon the first day of May, which is called Beltan, or Bàl-tein-day, all the boys in a township or hamlet meet in the moors. They cut a table in the green sod, of a round figure, by casting a trench in the ground of such a circumference as to hold the whole company. They kindle a fire, and dress a repast of eggs and milk in the consistence of a custard. They knead a cake of oatmeal, which is toasted at the embers against a stone. After the custard is eaten up, they divide the cake into so many portions, as similar as possible to one another in size and shape, as there are persons in the company. They daub one of these portions all over with charcoal, until it be perfectly black. They put all the bits of the cake into a bonnet. Everyone, blindfold, draws out a portion. He who holds the bonnet is entitled to the last bit. Whoever draws the black bit is the devoted person, who is to be sacrificed to Baal, whose favour they mean to implore, in rendering the year productive of the sustenance of man and beast. There is little doubt of these inhuman sacrifices having been once offered in this country as well as in the East, although they now pass from the act of sacrificing, and only compel the devoted person to leap three times through the flames; with which the ceremonies of the festival are closed."

[1] "Ethnology in Folklore," pp. 32 and 163.

I may conclude this article by referring to similar practices in Brittany, where Baring-Gould has so successfully studied them.[1]

The present remnants of the old cult in the different parishes are now called "Pardons"; they are still numerous. I give those for the May and August festivals (p. 83):—

MAY.

Ascension Day	Bodilis, Penhars, Spezet (at the Well of S. Gouzenou), Landevennec, Plougonnec.
Sunday after Ascension Day	Trégoat, St. Divy.
Whit Sunday	Kernilis. Plouider; Edern; Coray; Spezet (Chapel of Cran).
,, Monday	Quimperlé (Pardon des Oiseaux); Pont l'Abbé (Pardon des Enfants); Ergué-Armel, La Forêt, Landudal, Ploneis, Landeleau, Carantec.
,, Thursday	Gouezec (Les Fontaines).

AUGUST.

First Sunday in August ...	Pleyben (horse races); Plébannalec; Pouldreuzic; Plougomelin; Huelgoët; S. Nicodème in Plumeliau (M.), Cattle blessed; second day horse fair, and girls sell their tresses to hair merchants.

Judging by the "pardons," the solstitial celebrations are not so numerous as those connected with the May year. The bonfire is built up by the head of a family in which the right is hereditary. The fire has to be lighted only by a pure virgin, and the sick and feeble are carried to the spot, as the bonfire flames are held to be gifted with miraculous healing powers. When the flames are abated, stones are placed for the souls of the dead to sit there through the remainder of the night and enjoy the heat. "Every member of the community carries away a handful of ashes as a sovereign cure for sundry maladies. The whole proceeding is instinct with paganism" (p. 75).

With regard to the accompanying sacrifices, we read:—"In ancient times sacrifices were made of cocks and oxen at certain shrines now they are still presented, but it is to the chapels of saints. S. Herbot receives cows' tails, and these may be seen heaped upon his altar in Loqeffret. At Coadret as many as seven hundred are offered on the day of the 'pardon.' At S. Nicolas-des-Eaux, it is S. Nicodemus who in his chapel receives gifts of whole oxen, and much the same takes place at Carnac."

NORMAN LOCKYER.

SCIENTIFIC EXPLORATION IN CENTRAL ASIA.[1]

IT is with a lingering feeling of regret that we recognise how different, of necessity, are the explorations of the present day from those of fifty years ago. No longer is it possible, except in rare instances, for a traveller to return with tales of new discoveries of lakes, sources of rivers, mighty peaks, and of the strange peoples that dwell there. Much work still remains, but it is of a more scientific nature, and therefore will probably provide matter which when published may be less entertaining and less widely read. When a traveller makes a speciality of one particular branch of science, as Dr. Gottfried Merzbacher does in his volume on "The Central Tian-Shan Mountains," to the almost entire exclusion of all others, it follows that he can only appeal to a limited number of readers; to those, in fact, who are interested in the study of geology and glaciers. We would, however, make this reservation, that the photographs which adorn this book are exceptionally beautiful representations of snow scenery, and will more than satisfy the ordinary reader as well as the man of science, and that the map is of great general value.

For two seasons, 1902–3, did Dr. Merzbacher and his companions labour in the central Tian-Shan Mountains which lie north-east of Kashgar. Russian explorers have visited this district many times, but the main backbone of the range has never been closely explored, and Dr. Merzbacher was able to discover and correct many errors in existing maps. We would here point out the growing necessity for the closer interchange of information between the various scientific societies of different countries. Dr. Merzbacher met a Russian expedition which to his delight was not intending to work over quite the same tract of country, while Dr. Friedrichsen and Signor Giulio Brocherel have already published the results of their explorations of the same range, which were being undertaken almost simultaneously with those of Dr. Merzbacher and his companions. Healthy rivalry is to be encouraged, but such overlapping of work as this is regrettable.

In this volume, which is of the nature of a preliminary report, Dr. Merzbacher has embodied observations on the present and past glacier conditions of the Tian-Shan Mountains, and on peculiarities in the physical features of its valley formations, subjects to which, throughout the expedition, his attention was specially directed. A more detailed report, however, is to follow when his rich collections have been scientifically examined and arranged. We trust that the botanical, zoological, and climatological observations, which have been almost entirely omitted from this volume, will be included in the more detailed report. We cannot help feeling that a preliminary volume, such as this is intended to be, should have included some reference to these other subjects, while some of the geological and glacial notes might have been left to the more detailed report.

The care with which Dr. Merzbacher explored is worthy of the highest praise, leaving little or nothing for any future travellers in this region to accomplish. He made his winter quarters at Kashgar, but was not content to wait for more clement weather, and made many useful excursions during the winter months, which happened to be unusually mild. It would be out of place to attempt here a description, however short, of his journeyings, and indeed, without a map, it would be nigh impossible to follow any such description. Each glacier, each valley, each ridge is in turn visited, surveyed, and described. The position of the great peak of Khan-Tengri

FIG. 1.—Telephotographic View of Khan-Tengri (about 23,600 feet), taken from North, from the Middle Course of the Bayumkol Valley. Distance about 24 miles. From "The Central Tian-Shan Mountains, 1902–1903."

[1] "The Central Tian-Shan Mountains, 1902–1903." By Dr. Gottfried Merzbacher. Pp. ix+285. (London: John Murray.) Price 12s. net.

(23,622 feet) was correctly fixed, and the discovery was made that this, the culminating eminence of the whole Tian-Shan, does not stand in the main watershed, and is not a nucleus of converging ranges, but is situated on a secondary spur which projects from the main range far to the south-west. The true "nucleus" is the so-called "Marble Wall," which in lieu of a better name Dr. Merzbacher has christened after the president of the Imperial Russian Geographical Society Mount Nicholas Mikhailovich! The Inylchek glacier was found to have a total length of from forty-three to forty-six miles, in place of six to eight miles as previously supposed, and another equally large glacier was discovered but not visited. In the matter of climbing Khan-Tengri, which has been sometimes wrongly assumed to have been the main object of this expedition, Dr. Merzbacher points out the difficulties, which will probably have the result of exciting someone to make the attempt.

An accident which resulted in the unfortunate destruction of many photographic plates gave the energetic traveller an excuse for revisiting some of the ground already traversed, and enabling him, owing to the finer weather, to take still better photographs. Dr. Merzbacher's visit to the alpine lakes, such a rare phenomenon in the central Tian-Shan, and his notes thereon are of great interest, but as winter was closing in work became more difficult, and the expedition finally reached Tashkent *viâ* Kulja.

Regarding this volume as a preliminary report Dr. Merzbacher deprecates drawing conclusions from the facts noted until his rich materials have been examined by competent experts. He however mentions one point on which his scientific conviction is settled once and for all, namely, that for the Tian-Shan also an Ice age has to be accepted.

Photography was used on this expedition to an unprecedented extent, many beautiful views being due to the telephotographic process, which was used with excellent results. In addition to botanical and zoological collections climatic observations were taken twice daily, while the map was compiled with great care, and is also well drawn and beautifully reproduced. It is a pity that the same symbol should have been used to denote permanent villages and the pasturages, which are only visited at certain seasons by the Kirghiz herdsmen.

This volume, which is published under the authority of the Royal Geographical Society, is a worthy record of scientific work carried out under great difficulties. The author is to be warmly congratulated.

A LARGE-HEADED DINOSAUR.

THE mounted skeleton of *Triceratops prorsus*, of which a note by Mr. Charles W. Gilmore, preparator to the department of geology in the United States National Museum, Washington, has recently been published[1] with two plates, is interesting as displaying another Dinosaur of a distinct and very remarkable type, differing entirely from the numerous series of bipedal forms with which we are now familiar from the reconstructed skeleton of the iguanodon and its allies, and also from the ponderous quadrupedal, long-necked, small-headed Diplodocus, Brontosaurus, and Cetiosaurus types of gigantic herbivorous reptiles. Compared with these latter, Triceratops was a quadrupedal reptile of quite moderate size, the skeleton, according to the late Prof. Marsh, being not more than 25 feet in length and 10 feet in height. The present reconstruction by Mr. Gilmore still further reduces its length by the omission of six of the presacral vertebræ (introduced by Prof. Marsh), so that, as now restored, its total length is only 19 feet 8 inches.

The striking feature, which remains unchanged, is the skull, which is fully 6 feet long, and is consequently just one-third of the entire length of the skeleton as now set up.

Two powerful horn-cores of the bovine type, $2\frac{1}{2}$ feet in length, rise from the frontal bones of the skull, at the base of which are the round bony orbits. The snout is narrow and pointed, and carries a third smaller horn upon the nasal bone. Behind the pair of frontal horns is an immense frill of bone spreading back over the occipital region and covering the first six cervical vertebræ; it was 2 feet 6 inches long and 3 feet broad, resembling an immense Elizabethan ruff, ornamented with about twenty-four pointed bosses of bone along its border. The rostrum and predentary bones were armed with pointed horny beaks, the teeth being confined to the maxillary and dentary bones, forming a single series in each jaw. They are remarkable as having two distinct fangs, placed transversely in the jaw, with distinct sockets, and are displaced vertically; the successional teeth cut their way between the alveolar margin and the adjacent root of the old tooth, or between the two roots. Prof. Marsh had published a restoration of this dinosaur in 1891 (see *Geol. Mag.*, plate vii.), the chief difference between which and the present skeleton set up by Mr. Gilmore being the reduction in the number of the presacral vertebræ, already referred to, and the placing of the limbs, especially the fore-limbs (the humerus and the radius and ulna), in a

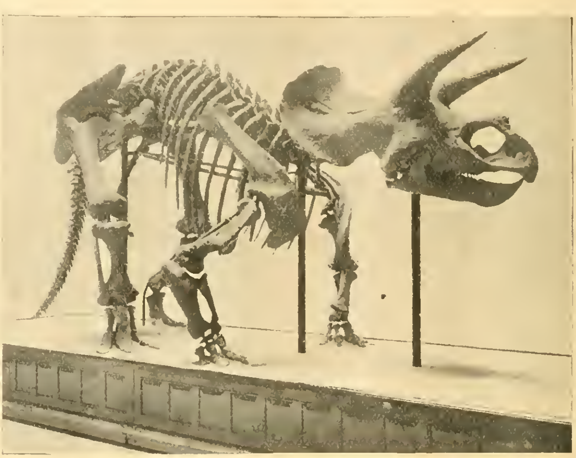

FIG. 1.—Skeleton of *Triceratops prorsus* in the U.S. National Museum. Three-quarters front view.

[1] *Proc. United States National Museum*, Washington, vol. xxix., pp. 433–435, with plates i. and ii., 1905.

more flexed and diverging position to enable the head of the animal in browsing to approach nearer to the ground. The bony cores on the skull were sheathed in horn as well as the beaks, and there is evidence of a dermal armature of bosses and spines which once covered the dorsal and lateral region of the creature's body. Mr. Charles R. Knight has given a spirited restoration of this animal in the *Century Magazine* (1897, p. 18). A life-size *papier-maché* reproduction of Triceratops has been made in America by Mr. Lucas, and it is to be hoped a copy may shortly be secured for the Natural History Museum in Cromwell Road. H. W.

NOTES.

THE King has conferred the honour of Knighthood upon Prof. A. Pedler, C.I.E., F.R.S., Director of Public Instruction, Bengal, and Vice-Chancellor of the Calcutta University.

WE are requested to announce that the endowment fund now being raised for the family of the late Prof. G. B. Howes, F.R.S., will be closed shortly, and all intending contributors are asked to send their contributions without delay to the treasurer, Mr. Frank Crisp, at 17 Throgmorton Avenue, London, E.C.

AT a meeting of the Academy of Natural Sciences of Philadelphia on December 5, 1905, Dr. Dixon announced that Mr. D. M. Barringer and Mr. B. C. Tilghman, members of the academy, had notified him of their discovery that the crater of Coon Mountain, or Coon Butte, in northern Arizona, twelve miles south-east of Cañon Diablo station on the Atchison, Topeka and Santa Fé Railway, is an impact crater, and not a crater produced by a steam explosion, as has been supposed since the examination made of it by members of the United States Geological Survey. It appears from their work that the large crater and elevation known as Coon Mountain is the result of a collision with the earth of a very large meteorite or possibly a small asteroid, fragments of which are well known to the scientific world by the name of the Cañon Diablo siderites. The investigations show (1) that the formation of the crater and the deposition of the meteoritic material were simultaneous; (2) that meteoritic material has been found 500 feet below the surface of the centre of the crater; (3) that sandstone supposed to be in place exists less than 1000 feet below the surface of the centre of the crater. The authors have presented to the academy for publication two comprehensive papers in which they set forth in full their reasons for the above statements.

A COPY of the programme of the excursions arranged in connection with the International Geological Congress, to be held in Mexico during next September, has just reached us. Excursions will take place before, during, and after the congress. Before the business meetings actually begin, four excursions are provided for visitors. The first excursion, which will last four days and be confined to 250 persons, is to be to the east from Mexico through Jalapa to Vera Cruz, returning to Mexico through Esperanza. The second excursion to the south is to extend to eight days, and is limited to 40 persons. Arriving at Esperanza, included in the first trip, the party will proceed to Tehuacan and thence to Oaxaca. Puebla will be taken on the return journey. The third excursion, confined to 30 members, will include visits to the volcanoes of Toluca, San Andrés, and Jorullo, and will last fourteen days, nine of which will be on horseback. The last of these trips is to the geyser district of Ixtlán and to the volcano, Colima. During the progress of the congress short journeys will be made to Pachuca, to Cuernavaca, and other places near Mexico. At the close of the conferences an excursion to the north, of twenty days, will take place. Salamanca, Guanajuato, Zacatecas, Mapimí, Conejos, Ciudad, Parras, and other localities will be visited. Another excursion after the meeting will be to the isthmus of Tehuantepec. The following subjects will be discussed at the congress:—(1) Climatic conditions during the geological epochs, when Messrs. G. Boehm, T. C. Chamberlin, W. B. Clark, W. H. Dall, W. M. Davis, A. Heilprin, V. Uhlig, and S. W. Williston will take part. (2) The relations between tectonics and eruptive masses: Messrs. A. Bergeat, A. Dannenberg, G. K. Gilbert, J. P. Iddings, A. Karpinski, A. Lacroix, and E. Naumann will speak. (3) The genesis of metalliferous veins: Messrs. B. von Inkey, F. Klockmann, W. Lindgren, W. B. Phillips, J. E. Spurr, and W. H. Weed will participate. (4) The classification and nomenclature of rocks: Messrs. Wh. Cross, J. P. Iddings, A. Karpinski, A. Lacroix, A. Osann, W. B. Phillips, H. S. Washington, and F. Zirkel will take part in the discussion. Communications may be addressed to the general secretary, M. Ezequiel Ordóñez, 5a del Ciprés, No. 2728, Mexico, D. F.

THE stone implements of the Zambesi valley near Victoria Falls, noted by Mr. Lamplugh in his report on the district (see NATURE, p. 112), and more fully described by Colonel Feilden in a letter recently printed in NATURE (p. 77), possess much interest in view of their possible high antiquity. At a meeting of the Geological Society of South Africa on October 30, 1905, Mr. J. P. Johnson, of Johannesburg, in giving an account of a further collection of these implements which he had made during a recent visit to the falls, stated that some of the specimens appear to show the transitional stage between the Eolithic and Palæolithic cultures. In the same paper the occurrence of implements of the "pygmy" type near Bulawayo is recorded.

IN the second part of the *Bergen's Museums Aarbog* for 1905, Mr. P. Bjerkan describes the ascidians collected by the Norwegian fishery-steamer *Michael Sars* from 1900 to 1904, while Mr. H. Brock does the same for the hydroid polyps obtained during the last two years. Three ascidians regarded as new are named by the former author, one of these representing a new genus; but all the hydroids appear to be identified with previously known forms. The organisation of Cephalodiscus has been recently fully investigated by Dr. H. Schepotieff, who records the results of his studies in a third article; while Mr. O. Bidenkap supplies a list of Arctic bryozoans.

To the October issue of the *Proceedings of the Philadelphia Academy of Sciences* Dr. J. W. Haishberger contributes two interesting papers on the flora of the Bermudas. In the first of these the general character of the flora, which is evidently of comparatively recent introduction, is discussed, and the different zones described. The second paper, on the other hand, is devoted to an explanation of the origin of the curious "hour-glass-conformation" of the stem of the Bermuda palmetto (*Sabal blackburniana*), long ago described in a letter from Mr. O. A. Reade to Sir Joseph Hooker. The explanation, according to the author, is simplicity itself, the constrictions being caused by unfavourable seasons of excessive drought.

IN a recent issue (vol. xxi., art. 14) of the Bulletin of the American Museum, Prof. H. F. Osborn describes two new generic types of carnivorous dinosaurs from the

Laramie Cretaceous, namely, *Tyrannosaurus rex* and *Dynamosaurus imperiosus*. The former appears to have been unprovided with armour, and is estimated to have measured 39 feet in length; it walked on the hind-limbs only, with the top of the skull raised about 19 feet from the ground. On the other hand, Dynamosaurus was an armoured type with about a dozen lower teeth, and a number of curious prominences on the inner margin of the jaw. In this comparatively small number of teeth it seems to differ from Leidy's Dinodon, in which some of the teeth were serrated. A third type, *Albertosaurus sarcophagus*, is based on a skull from Albert province, Canada. It is apparently more specialised than Dinodon in the reduction of the truncated anterior teeth, and more primitive than Dynamosaurus in the possession of a larger number of teeth, which are of a less specialised type.

We have received four numbers (inclusive of one devoted to the record of last year's meetings) of the fourteenth volume of the *Transactions of the Academy of St. Louis*. In the bulkiest of these, comprising no less than 248 pages, Mr. T. L. Casey revises the American representatives of that section of the staphylinid or short-clytraed beetles known as the Pœderini, the memoir being, of course, interesting only to specialists. In a second paper Mr. S. Weller describes, under the name of Paraphorhynchus, a new genus of rhynchonella-like brachiopods from the Kinderhook formation of the Mississippi. In a third paper the fresh-water molluscan fauna of McGregor, Iowa, forms the subject. Mr. F. C. Baker communicates some interesting information with regard to the pearl-fishery of that district. The unios are fished up by means of a dredge armed with four-pronged "crowfoot" hooks, and it is believed that malformed specimens are more likely to contain pearls than those with normal shells. These "crippled" mussels, or "clams," are believed by the writer to owe their injuries to the action of the dredge itself.

The last published number of *Biometrika* contains an important paper by Mr. A. O. Powys on fertility, duration of life and reproductive selection in man, with their mutual relations. Several of his results, which are derived from the statistical data of New South Wales, are of high interest. He finds that women with families of five or six children have a better expectation of life after forty-five than mothers of either a larger or smaller number of offspring. The married have a similar advantage over the single. Another conclusion drawn by Mr. Powys from his figures is that "up to the present there is but little Malthusian restraint upon the population in New South Wales what little there may be apparently being confined to the professional, domestic and commercial classes." He confirms Prof. Karl Pearson's view that society is at present being recruited from below—mainly from the artisan class. A useful craniological contribution to the study of inter-racial correlation in man is furnished by E. Tschepourkowsky, of Moscow, and Mr. E. H. J. Schuster publishes the first instalment of a catalogue of the fine collection of skulls in the Oxford Museum, on the basis of a manuscript catalogue prepared some years ago by Dr. Hatchett Jackson. Dr. Brownlee puts the facts of the immunity against small-pox conferred by vaccination and re-vaccination on a firm statistical basis, and Mr. John Blakeman supplies probable error tests of the significance or otherwise of the difference between correlation ratio and coefficient, and consequently of the existence or non-existence in a given population of true linear regression. Mr. Latter deals with the measurements of 1572 specimens of cuckoos' eggs. These, he considers, tend to confirm Prof. Newton's suggestion that there are certain subraces of cuckoos which "in the main confine their attentions, generation after generation, each to its own particular variety of foster-parent." In the "Miscellanea," Mr. W. Palin Elderton proposes new methods for the calculation and adjustment of moments.

Mr. J. H. Hart, the superintendent of the Royal Botanic Gardens, Trinidad, records the discovery of a water-plant, probably a species of Nitella, in the Pitch Lake La Brea, which produces peculiar pear-shaped organs on the stems. These are hollow, and have large openings into the interior, fringed with simple or branched hairs, and within some of them mosquito larvæ were observed, apparently caught and killed by the plant. The suggestion, therefore, is made that the plant might be useful for mosquito destruction.

The use of copper sulphate in the purification of water supplies has from time to time been referred to in these columns. Dr. Howard Jones, the medical officer of health for Newport, Mon., reports the successful employment of the method at Newport. Copper sulphate, to the extent of 1 lb. per million gallons, proved efficient in removing an objectionable fishy odour and rendering the water of the reservoirs bright and clear (*Water*, December 15, 1905).

At a meeting of the Royal Statistical Society on December 19, 1905, Drs. Newsholme and Stevenson read an important paper on the decline of human fertility in the United Kingdom and other countries as shown by corrected birth-rates. They pointed out that corrected birth-rates measure the tendency of communities to increase by natural means, *i.e.* by the excess of births over deaths, or, in other words, their fertility, just as corrected death-rates measure the tendency to decrease. The ordinary "crude" birth-rate is deceptive, since it fails to make allowance for the fact that some populations include a much larger proportion than others of wives at reproductive ages, and for the further fact that the potential fertility of women steadily decreases during the reproductive period until its end is reached. The necessity for correction was illustrated by numerous examples. Thus the crude birth-rate of Ireland in 1903, 23·1, is little higher than that of France in 1902, which was 21·7; but the French birth-rate is practically unaltered by correction, whereas that of Ireland is increased to no less than 36·1. This remarkable result is due to the fact that, although both countries have approximately the same proportion of women aged fifteen to forty-five in their populations, 52·5 per cent. of these in France are married as against 32·5 per cent. in Ireland. Of the countries studied, Ireland alone shows an increase of fertility (3 per cent.) during the last twenty-two years. The conclusion arrived at is that the decline in the birth-rate is associated with a general raising of the standard of comfort, and is an expression of the determination of the people to secure this greater comfort; and the authors anticipate as a result a deterioration of the moral, if not also of the physical, nature of mankind.

Ciel et Terre for November 15, 1905, contains a useful summary of an elaborate discussion by M. A. Angot on the temperature of France and adjoining countries. The original paper appeared in a recent number of *Annales de Geographie*; it deals chiefly with the temperature of France, to which the following remarks entirely refer. As regards the annual means, the isotherms in the north of the country show a decided inclination from north-west to south-east; this is due to the fact that, generally speak-

ing, the land is colder than the sea above lat. 45°, and warmer to the south of that latitude. The lowest mean value is found between Lille and Dunkirk, being about 40° F.; the maximum is on the coast of Nice, and is slightly above 50°. Except on part of the coast of Brittany, the whole of France lies in the zone of moderate climates, in which the annual amplitude is between 50° and 68°. The lowest minima are found in the east; in the winter of 1879–80, temperatures of −22° were recorded. Contrary to current opinion, the highest minima are not on the coast of Nice, where occasionally the cold is very severe, but on the south-west of Brittany and at Ushant, where frost is extremely rare. In the latter regions the absolute maxima are not so high as in other parts. At Ushant a reading of 86° has not been recorded. The highest maxima are found near the Mediterranean, between Carcassonne and Avignon. At Montpellier, a temperature of 109° was recorded on July 19, 1904; this is the highest reading known in France. The details of the discussion are being published in the *Annales* of the French Central Meteorological Office.

IN the *Engineering Magazine* for December, 1905, Mr. E. Guarini gives some striking illustrations of the electric railway at Gruyères. The description is typical of much of the work now being done in the construction of electric railways in Switzerland, where the abundant water-power is especially favourable to the development of such enterprises.

IN the *Engineering and Mining Journal* Mr. F. L. Hoffman gives details of the fatal accidents in coal mining in the United States in 1904. The fatal accident rate was 3·38 per thousand workmen employed, as against an average of 3·03 per thousand for the decade 1895–1904. The relative mortality due to fatal accidents continues to be unreasonably high, and the problem of the prevention of such accidents remains the most serious and perplexing in coal-mining operations.

THE paper recently read by Mr. E. M. Speakman on the determination of the principal dimensions of the steam turbine before the Institution of Engineers and Shipbuilders in Scotland, gave rise to a discussion of great interest in which important information was given regarding the application of the steam turbine to marine work. It was pointed out that the trials of the Cunard steamship *Carmania*, the largest turbine steamer yet built, had fulfilled in every way the highest expectations of all connected with the ship.

AT the last meeting of the Institution of Mechanical Engineers a paper on the behaviour of materials of construction under pure shear was read by Mr. E. G. Izod. The results obtained seem to point to the fact that there is no common law connecting the ultimate shearing stress with the ultimate tensile stress. With crystalline materials, such as cast iron or those with very little or no elongation, the former exceeds the latter by as much as 20 per cent. or 25 per cent., while from fibrous material or, more properly speaking, those with a fairly high measure of ductility, the ultimate shear stress may be anything from 0 per cent to 50 per cent. less than the ultimate tensile stress.

THE second part of the report of the Ontario Bureau of Mines for 1905 is devoted to an important monograph on the cobalt-nickel arsenides and silver deposits of Temiskaming by Mr. W. G. Miller. It covers sixty-six pages, and is illustrated by twenty-eight reproductions of photographs and two geological maps. The deposits were discovered in October, 1903, during the construction of the Temiskaming and Northern Ontario Railway. They occupy narrow, practically vertical fissures cutting through a series of unusually slightly inclined metamorphosed fragmental rocks of Lower Huronian age. A few veins have also been found in the adjacent diabase. The chief ores are native silver, smaltite, niccolite, and chloanthite, with which are associated argentite, pyrargyrite, dyscrasite, erythrite, and other comparatively rare minerals. None of the veins are wide, the maximum being about 18 inches. Some that have been traced 100 feet or more average 1 inch in width. The production during the quarter ended June 30 was 537 tons, the average metallic contents being:—silver, 4·158 per cent.; cobalt, 6·89 per cent.; nickel, 3·09 per cent.; and arsenic, 30·91 per cent. An interesting mineral occurrence is a white clay-like material in the weathered parts of the veins. The white colour of this mineral is due to the intermixture of the green nickel arsenate, annabergite, with the pink cobalt bloom, the mineral showing on analysis 29·30 per cent. of nickel oxide, 6·43 per cent. of cobalt oxide, and 38·31 per cent. of arsenic pentoxide. Hitherto New Caledonia has had practically a monopoly of the world's production of cobalt. Worked primarily for silver with their high values in that metal, the Ontario deposits, with nickel and arsenic as by-products, should prove a strong competitor, even if they should not control absolutely the cobalt market.

MESSRS. F. VIEWEG AND SON, Brunswick, have just published the ninth edition of Prof. A. Bernthsen's "Kurzes Lehrbuch der organischen Chemie." The work appeared originally in 1887; and in the preparation of the present edition Dr. E. Mohr is associated with the author.

STUDENTS and others interested in microscopy will be glad to have their attention directed to new lists of microscopic slides and of second-hand instruments and accessories just issued by Messrs. Clarke and Page, Leadenhall Street, E.C. Special mention should be made of the marine and botanical slides, which are fine examples of cutting, staining, and mounting. A series of objectives corrected for photomicrography is also of noteworthy interest.

A LIST of meteorological instruments for observatories and climatological stations has been received from Messrs. Pastorelli and Rapkin, Ltd., Hatton Garden, E.C. Instruments of various forms for the accurate determination of pressure, temperature, rainfall, and other meteorological elements are described and illustrated in the list, which may be consulted with advantage by anyone desiring to equip a station with serviceable apparatus, or to supplement instruments already in use.

MESSRS. EASON AND SON, LTD., of Dublin, have sent us four of their time-saving indexed diaries for 1906. The "Every Hour" diary provides a convenient record of appointments, special business and events, for any hour of any day during the year. The "Cabinet Scribbling" diary is furnished with a double index for rapid reference, the first arranged as a record for such items as addresses and current literature, the second being to the first of each month.

A COPY of "Hazell's Annual" for 1906 has been received. This twenty-first issue maintains the high reputation of its predecessors. To keep in touch with the important foreign events of the year, numerous foreign biographies have been added, and the text of many treaties included. Some sixteen pages are devoted to scientific matters, most of them being given to scientific progress during 1905.

Prominence is also given to higher educational matters, and the man of science will find much in this section to interest him.

MESSRS. CHARLES GRIFFIN AND CO., LTD., have published the twenty-second annual issue, that for 1905, of the "Official Year-book of the Scientific and Learned Societies of Great Britain and Ireland." This useful work of reference is already well known as a trustworthy guide to the scientific societies and their work. Though the volume is very comprehensive, we miss a reference to the Geographical Association and to the Public Schools Science Masters' Association. The editor might consider the advisability of including associations dealing with educational science.

A NEW vernier rule and scale designed by Mr. S. Irwin Crookes has been received from the maker—Mr. W. H. Harling, 47 Finsbury Pavement, E.C. The rule is divided on one face into inches and eighths of an inch and centimetres and millimetres; the other face has on the edges divisions and numbers representing degrees from 0 to 150, and a barometer scale reading from 20 to 32. A metal vernier slides in a slot cut through the middle of the length of the rule, and it is divided in four different ways to read fractions of the four scales on the rule. The device should be valuable in making students familiar with the use of the vernier on many precise scientific instruments.

THE second annual issue of the "Science Year Book" (5s. net), edited by Major B. F. S. Baden-Powell, has been published by Messrs. King, Sell and Olding, Ltd. Several new features have been introduced, and every care appears to have been taken to make the volume serviceable to men of science and others interested in natural knowledge. The year book includes a diary containing at the head of every daily page the astronomical and meteorological particulars of the day likely to be of interest, and blank spaces for recording results of observations. Other characteristics are tables of useful data, an astronomical ephemeris, maps of the constellations, charts of planetary positions during 1906, and various statistics and notes referring to matters not usually included in ordinary calendars and almanacs. There are also short summaries of progress in science during last year, an eclectic bibliographical directory, and a list of scientific books published last year. The year book is thus a convenient and helpful companion for the study, laboratory, or observatory.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY:—

Jan. 4.	4h. 12m. to 5h. 10m.	Moon occults ξ^2 Ceti (mag. 4·3).
,, 4.	15h.	Mercury at greatest elongation, 23° 0′ W.
,, 5.	5h.	Venus in conjunction with Uranus, Venus 0° 6′ N.
,, 5.	14h. 45m. to 15h. 16m.	Moon occults *f* Tauri (mag. 4·3).
,, 6.	14h. 52m. to 15h. 40m.	Moon occults γ Tauri (mag. 3·9).
,, 14.	11h. 1m. to 11h. 58m.	Moon occults σ Leonis (mag. 4·1).
,, 15.	Venus.	Illuminated portion of disc = 0·993. Of Mars = 0·923.
,, 15.	11h. 2m.	Minimum of Algol (β Persei).
,, 18.	7h. 51m.	Minimum of Algol (β Persei).
,, 26.	8h.	Saturn in conjunction with Moon. Saturn 0° 31′ S.
,, 28.	6h. 17m. to 8h. 14m.	Transit of Jupiter's Sat. III.

A FOURTH NEW COMET (1905*e*).—A telegram from the Kiel Centralstelle announces the discovery of another new comet by the Flagstaff observers. This object was discovered, presumably, from the examination of a photograph, by Mr. Lowell, who gives its position on November 29, 1905, at 9h. 27m. (Flagstaff M.T.), as follows:—

R.A. = 22h. 32·2m., dec. = −8° 42′.

The apparent motion of the comet was either in a north-east or a south-west direction, and the photograph showed that the body was accompanied by two tails.

The above position is in the constellation Aquarius, about half-way between ϕ Aquarii and ι Ceti.

NEW ELEMENTS AND EPHEMERIS FOR COMET 1905*c*.—A new set of elements and a daily ephemeris for comet 1905*c* (Giacobini) are given by Herr E. Strömgren in No. 4062 of the *Astronomische Nachrichten*.

These elements, and an extract from the ephemeris, are given below.

T = 1906 Jan. 22·666 (*M.T. Berlin*).

$$\left.\begin{aligned} \omega &= 198^\circ\ 21'{\cdot}67 \\ \Omega &= 91\ \ 55{\cdot}27 \\ i &= 43\ \ 37{\cdot}08 \end{aligned}\right\} 1905{\cdot}0$$

$$\log q = 9{\cdot}34978$$

Ephemeris (12*h. M.T. Berlin*).

1906	α (true) h. m. s.	δ (true)	log γ	log Δ	Brightness
Jan. 5	17 23 54	− 1 35·7	9·7701	0·0425	7·97
,, 7	17 39 28	− 3 53·5	9·7313	0·0425	9·53
,, 9	17 55 31	− 6 15·9	9·6881	0·0441	11·53
,, 11	18 12 10	− 8 42·5	9·6398	0·0473	14·20
,, 13	18 29 33	− 11 12·8	9·5856	0·0520	17·83

The above positions are plotted on the accompanying chart, which shows approximately the apparent positions of the comet among the stars on the dates indicated.

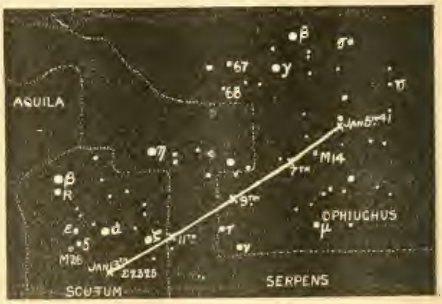

FIG. 1.—Path of Comet 1905*c*, January 5–13, 1906.

THE EXPECTED RETURN OF COMET 1892 V.—In *Circular* No. 84 from the Kiel Centralstelle, M. J. Coniel gives several provisional search-ephemerides, showing positions up to January 6·5, for comet 1892 V.

This comet was discovered by Holmes on November 6, 1892, and was observed during its apparition in 1899, when it passed through its perihelion on April 28. Its period is given by Zwiers as 6·874 years.

MICROMETER MEASURES OF DOUBLE STARS.—The results of a series of micrometer measures of eighty-three double stars, taken from the Struve, Burnham, and Hussey catalogues, are published in No. 4054 of the *Astronomische Nachrichten* by Herr H. E. Lau. The observations were made during March, 1905, with the Urania-Sternwarte (Copenhagen) refractor, of 246 mm. aperture and 4·1 metres focal length, fitted with a Cooke position micrometer.

For each double, the time of observation, the position-angle, the distance, the magnitudes of the components and the power used are given, whilst short comparisons with other measures and notes regarding the probable character and motion are generally added.

FRENCH ASTRONOMICAL "ANNUAIRES."—We have received two French "Annuaires" which are of particular interest to astronomical workers, the one being the "Annuaire du Bureau des Longitudes" (price 1.50 francs), the other the "Annuaire astronomique et météorologique" (price 1.50 francs), which is published by M. Flammarion.

The former volume contains 352 pages devoted to astronomical matters, in addition to which there are three appendices (188 pages) dealing with eclipse observations. In the first of these M. Bigourdan gives a large number of summarised instructions concerning the observations which may be made during eclipses, pointing out the most suitable observations to be undertaken with the instruments readily available. In the second the same writer gives an extremely interesting summary of the observations made in all parts of the shadow-track during the recent eclipse, whilst the third appendix is devoted to a short account, by Prof. Janssen, of his own observations made in Spain on August 30.

M. Flammarion's "Annuaire" will be found to be especially suitable for amateur observers, some interesting phenomenon being given for every day in the year. It contains practically all the data to which the amateur has any need to refer, and the *résumé* of the more important astronomical advances during the past year should prove both interesting and useful.

PRIZES AWARDED AND PROPOSED BY THE PARIS ACADEMY OF SCIENCES.

AT the annual meeting of the academy of December 18, 1905, the president delivered his annual address, and announced the list of prizes awarded in 1905 as follows:—

The Francœur prize is awarded to M. Stouff, for the whole of his mathematical works.

A Montyon prize to M. Mesnager, for his theoretical and experimental work on the theory of elasticity and the resistance of materials. The Poncelet prize to M. Lallemand, for his work on the figure of the earth and for his improvements in geodesic instruments.

The extraordinary prize of 6000 francs has been divided, Colonel Gossot and M. Liouville receiving 4000 francs, for their work on ballistics; M. Carré 1000 francs, for improvements in the navigation of submarines; and M. Merlu 1000 francs, for improvements in the furnaces of marine boilers. The Plumey prize is divided between M. Maurice (2500 francs), for a device for the recuperation of heat in boilers, and M. de Maupeou d'Ableiges (1000 francs), for his investigations of the theory of impact.

The Pierre Guzman prize is not awarded, but M. Perrotin receives 2000 francs from this foundation for the whole of his astronomical work. The Lalande prize is awarded to Prof. W. H. Pickering, for his astronomical work, and especially for his brilliant researches on the satellites of Saturn; the Valz prize to M. Giacobini, for his work on comets; and the G. de Pontecoulant prize to Prof. J. C. Kapteyn, for the whole of his astronomical researches. Of the two memoirs on the theory of comets presented for the Damoiseau prize, that of M. Fayet is adjudged the better, M. Fabry, the author of the second memoir, receiving a prize from the funds of the Guzman prize.

The Gay prize is given to Dr. Cureau, for his accurate geodesic measurements in Africa. The Tchihatchef prize to the late M. Massenet, for geodesic work in Cochin China.

M. Jumau receives the Hébert prize for his book on electric accumulators; M. Georges Urbain the Hughes prize, for his researches on the rare earths; M. Henri Abraham the Gaston Planté prize, for his researches and books; and M. Gouy the La Caze prize, for the whole of his original work.

The Jecker prize is awarded to MM. Sabatier and Senderens, for their researches on the catalytic action of metals; Montyon prizes (unhealthy trades) to M. Donard, for his method of treating slaughter-house refuse, and to M. Carles, for his method of utilising wine residues; the La Caze prize to M. Albert Colson, for the whole of his researches; the Bordin prize to M. Paul Lebeau, for his researches on silicides. The Cahours prize is divided between M. Binet du Jassoneix and M. Kling.

M. G. Friedel receives the Delesse prize for his work in mineralogy; M. Gustave Dollfus the Fontannes prize, for his researches on Tertiary fossils; and M. Marcellin Boule the Alhumbert prize, for his work on the determination of the period of the latest volcanic eruptions in central France.

The grand prize of the physical sciences is awarded to M. Dangeard, for his researches on the development of the egg in the Ascomycetes and Basidiomycetes; the Desmazières prize to M. Ferdinand Renauld, for his memoir on the flora of Madagascar; the Thore prize to M. de Itsvanffi, for his memoirs on the fungi attacking the European vine, the Montagne prize being divided between M. Lutz (1000 francs) and M. Gallaud (500 francs).

In anatomy and zoology, M. C. Gravier receives the Savigny prize.

A Montyon prize is divided between M. L. C. Maillard (the indoxylic colouring matters of human urine), M. Albert Malherbe (researches on sarcoma), and M. Albert Le Play (experimental researches on intestinal poisons). Mentions are accorded to MM. H. Guilleminot, J. Beolt, and Edmond Loison. The Barbier prize is divided between M. J. Dechery and G. Rosenthal, M. Serini receiving a mention. The interest on the funds of the Bréant prize is divided between M. Vincent, M. Martel, and Dr. Remlinger. The Godard prize is accorded to Dr. A. Hogge; the Baron Larrey prize to M. H. Nimier, with very honourable mention to M. Marix; the Bellion prize to Dr. Pressat (malaria and mosquitoes) and MM. Alquier and Drouineau (glycogen and rational nutrition with sugar); the Mège prize to M. Beni-Barde, for his book on hydrotherapeutics; the Serres prize to M. F. Henneguy. The Dusgate prize is not awarded, but M. Onimus receives a very honourable mention.

In physiology the Montyon prize is shared by M. J. Lefèvre and M. J. Laurent. The Philipeaux prize is awarded to M. Victor Henri for his quantitative researches on diastases, M. L. Butte being accorded a mention for his researches on the glycogenic functions of the liver. The Lallemand prize is divided between M. and Mme. Lapicque and M. Jules Voisin, M. Crouzon receiving a very honourable mention. The question set for the Pourat prize was the origin of muscular glycogen. The only paper received on this subject was by M. Maignon, to whom the prize is awarded.

A Montyon prize for statistics is awarded to M. Edmond Gain, with a very honourable mention to M. Jules Fleury.

The Binoux prize is awarded to M. Paul Tannery.

M. Adolph Lieben receives the Lavoisier medal; MM. Senderens, Donard, Lebeau, Jumau, Urbain, Abraham, Gouy, Canovetti, and Leduc the Berthelot medal. The Trémont prize is awarded to M. Ch. Frémont, for his researches in the domain of mechanics; the Gegner prize to M. J. H. Fabre; the Lannelongue prize to Mme. Beclard and Mme. Cusco; the Wilde prize to M. Canovetti and M. Leduc (in equal parts); the Saintour prize to M. Édouard Piette and M. Marchis; the Petit D'Ormoy prize to M. Émile Borel (mathematical sciences) and M. Julien Costantin (natural sciences); the prize founded by Mme. la Marquise de Laplace to M. Fortier; and the Félix Rivot prize to MM. Fortier, Rodhain, Frontard, and Lefranc.

The subjects proposed by the academy for prizes for 1907 are as follows:—

The Francœur prize (1000 francs), for work or discoveries useful to the progress of the science of pure or applied mathematics; the Bordin prize (3000 francs), for the solution of a problem in the theory of algebraic surfaces; the Vaillant prize (4000 francs), for the integration of the equation

$$\frac{\partial^4 u}{\partial x^4} + 2\frac{\partial^4 u}{\partial x^2 \partial y^2} + \frac{\partial^4 u}{\partial y^4} = f(x, y)$$

under specified conditions; and the Poncelet prize (2000 francs), under conditions similar to those of the Francœur prize.

A Montyon prize (700 francs), for the invention or improvement of instruments useful to the progress of agriculture, the mechanical arts or sciences.

The extraordinary prize of 6000 francs, for an invention or discovery tending to increase the efficacy of the French naval forces; the Plumey prize (4000 francs), for improvements in the steam engine or any invention contributing to the progress of steam navigation.

The Lalande prize (540 francs), the Valz prize (460 francs), and the G. de Pontécoulant prize (700 francs), for the most interesting observation, memoir, or work in astronomy published during the year.

The Gay prize (1500 francs), for a study of the natural conditions in the Polar regions; the Tchihatchef prize (3000 francs), for exploration in the lesser known portions of Asia.

The Hébert prize (1000 francs), for a treatise or discovery in the practical use of electricity; the Hughes prize (2500 francs), for a discovery contributing to the progress of physics; the Gaston Planté prize (3000 francs), for a French author of a discovery, invention, or important work in electricity; the La Caze prize (10,000 francs), for works or memoirs contributing to the progress of physics; the Kastner-Boursault prize (2000 francs), for the best work on the applications of electricity in the arts, industry, or commerce.

The Jecker prize (10,000 francs), for works useful to the progress of organic chemistry; the Cahours prize (3000 francs), for the encouragement of young chemists; the Montyon prize (2500 francs and 1500 francs), for the discovery of a process rendering a trade or manufacture less unhealthy.

The grand prize of the physical sciences (3000 francs), for a study of underground water from the hygienic point of view; the Delesse prize (1400 francs), for work in geological or mineralogical science.

The Desmazières prize (1600 francs), for the best work during the year on cryptogams; the Montagne prize (1500 francs), to the French author of the best work on the anatomy, physiology, development, or description of the lower cryptogams; the Thore prize (200 francs), for the best work on the cellular cryptogams of Europe; the de Coincy prize (900 francs); the de la Fons-Mélicocq prize (900 francs), for the best botanical work on the north of France.

The Savigny prize (1300 francs), for the assistance of young travelling zoologists specially occupied with the study of the Egyptian and Syrian invertebrates.

A Montyon prize (2500 francs, mentions 1500 francs), for discoveries useful in the art of healing; the Barbier prize (2000 francs), to the author of a valuable discovery in surgical, medical, pharmaceutical, or botanical science; the Bréant prize (100,000 francs), for the discovery of a radical cure for Asiatic cholera or for pointing out the causes of cholera in such a manner that could lead to its total suppression. Failing these, the interest will be awarded annually for the proof of the existence in the air of substances playing a part in the production or propagation of epidemic disease. The Godard prize (1000 francs), for the best memoir on the anatomy, physiology, or pathology of the genito-urinary organs; the Baron Larrey prize (750 francs), for a memoir on military medicine, surgery or hygiene; the Bellion prize (1400 francs), for discoveries profitable to the health of man; the Mège prize (10,000 francs); the Chaussier prize (10,000 francs), for a memoir on legal or practical medicine.

A Montyon prize (750 francs) and the Philipeaux prize (900 francs), for work in experimental physiology; the Lallemand prize (1800 francs), for work on the nervous system; the Pourat prize (1000 francs), for a memoir on the utilisation of pentanes in animal organisms; the La Caze prize (10,000 francs), for a work on physiology.

The Montyon prize (500 francs), for a memoir on French statistics.

The Arago, Lavoisier, and Berthelot medals. The Trémont prize (1100 francs); Gegner prize (3800 francs); the Lannelongue prize (2000 francs); Wilde prize (4000 francs), for memoirs in the subjects of astronomy, physics, chemistry, geology, or experimental mechanics; the Saintour prize (3000 francs); the Petit d'Ormoy prize (two of 10,000 francs), one for pure and applied mathematics, the other for one of the natural sciences; the Leconte prize (50,000 francs); the Pierson-Perrin prize (5000 francs); the prize founded by Mme. la Marquise de Laplace; the Félix Rivot prize (2500 francs).

December 31, 1906, will be the last day for sending in memoirs for the above prizes. The prizes bearing the names of Tchihatchef, La Caze, Delesse, Wilde, and Leconte are awarded without preference of nationality.

VOLCANIC ROCKS FROM NEW ZEALAND.[1]

THE district dealt with in this memoir is part of the principal gold-field of New Zealand. The igneous rocks here, which are the source of the gold, are of Tertiary age, though an older series, of Palæozoic age, occurs in the same district. There had been no previous petrographical study of the rocks, of a kind at once comprehensive and detailed, when a specially made collection of 500 specimens was placed in the hands of Prof. Sollas for description, and the report now before us consequently contains much valuable material. Mr. McKay tells us that the principal object of invoking the aid of this well known petrologist was to place the nomenclature of the rocks on a more satisfactory footing. Whatever the object, we are glad to welcome the result, and we also accept gratefully the lavish illustration which attests the liberality of the New Zealand Government. There are upward of 100 plates, reproduced by "process" from photographs, most

FIG. 1.—Hyalopilitic Hypersthene-Andesite; thin slice photographed in polarised light, magnification about 20 diameters.

of them representing thin slices of rocks photographed from the microscope. A figure measuring 7 inches by 5 inches affords a much better conception of the micro-structure of a rock than can be gained from the illustrations in most petrographical memoirs.

The introductory section by Mr. McKay gives a historical account of the district, with bibliographical references, and also sets forth the bearings of Prof. Sollas's results upon the general geology of the district. The Tertiary volcanic rocks are all andesites, dacites, and rhyolites. We may note here a striking contrast with the southern part of New Zealand, where, in the neighbourhood of Dunedin, is found a great variety of phonolites, tinguaites, trachytes, and other types rich in alkalies. The sequence in the Cape Colville district is also of interest. The

[1] "The Rocks of Cape Colville Peninsula, Auckland, New Zealand." By Prof. Sollas, F.R.S. With an Introduction and Descriptive Notes by Alexander McKay, Government Geologist, N.Z. Vol. i. Pp. viii+289; with many plates. (Wellington, 1905.)

Eocene volcanic rocks were mostly andesitic flows and breccias; the Miocene wholly andesitic or dacitic, stratified tuffs with coal; the Pliocene a succession of rhyolitic flows and breccias.

The description by one geologist of specimens collected by another at the Antipodes is a division of labour which has drawbacks as well as advantages. Prof. Sollas, however, has faced the difficulty successfully, and the large amount of labour which he has expended on this study has produced results which have a value by no means confined to New Zealand geology. Arising from the detailed examination of the rocks, there are a number of more general questions of petrographical interest on which the author is able to throw light. One point is the recognition in the ground-mass of the so-called "pilotaxitic" andesites of an interstitial mosaic of quartz, which plays the same part as the glassy base in the "hyalopilitic" type. Another point is the discovery of a certain isotropic hydrated decomposition-product, which partly or wholly replaces the felspar crystals in some of the rhyolites. This was taken by Rutley for glass, and regarded as evidence of the re-fusion of the rock. Our author finds no evidence of devitrification in the glassy rhyolites of this district, but there may be considerable chemical alteration. The Palæozoic dyke-rocks are also described and discussed. They range from quartz-diorite, through "dacite-porphyrite," to dacite, the second being given as a new name to a type of intermediate characters which agrees generally with propylite as defined by Zirkel. We may remark that the term "dacite-porphyry" has been used by American petrologists for a rock not essentially different (see, *e.g.*, Iddings in *Bull.* 150 *U.S. Geol. Sur.* [1898], p. 233).

The report under notice is marked "vol. i.," and we may expect that the geological and petrological study of the Cape Colville district will yield further results of interest. One question which remains to be elucidated is that of the mode of occurrence and origin of the gold. Comparison with the well known Comstock district of Nevada suggests that careful chemical assays of the rocks, both fresh and decomposed, would give significant information on this point.

A. H.

INSECTS AS CARRIERS OF DISEASE.[1]

"Infinite torment of flies."—*Tennyson.*

THE last few years are marked in the annals of medicine by a great increase in our knowledge of certain parasitic diseases, and, above all, in our knowledge of the agency by which the parasites causing the diseases are conveyed.

Chief among these agencies, in carrying the disease-causing organisms from infected to uninfected animals, are the insects, and, amongst the insects, above all the flies. Flies, *e.g.* the common house-fly (*Musca domestica*), can carry about with them the bacillus of anthrax. Flies, ants, and other even more objectionable insects, are not only capable of disseminating the plague-bacillus from man to man, and possibly from rat to man, but they themselves fall victims to the disease, and perish in great numbers. They are active agents in the spread of cholera, and the history of the late war in this country definitely shows that flies play a large part in carrying the bacilli of enteric fever from sources of infection to the food of man, thus spreading the disease.

The diseases already mentioned are caused by bacteria. But flies also play a part in the conveyance of a large number of organisms which are not bacteria, but which, nevertheless, cause disease.

In considering the part played by flies in disseminating diseases not caused by bacteria, we can neglect all but a very few families, those flies which suck blood having alone any interest in this connection.

From the point of view of the physician, by far the most important of these families is the Culicidæ, with more than 300 described species and 5 subfamilies, of which two, the Culicina and the Anophelina, interest us in relation to disease. The gnats or mosquitoes are amongst the most graceful and most beautiful insects that we know; but they have been judged by their works and undoubtedly are unpopular, and we shall see that this unpopularity is well deserved. Gnats belong both to the genus Culex and to the genus Anopheles. The genus Culex, from which the order takes its name, includes not only our commonest gnat, often seen in swarms on summer evenings, but some hundred and thirty other species. Members of this genus convey from man to man the *Filaria nocturna*, one of the causes of the widely-spread disease filariasis. In patients suffering from this disease, minute embryonic round-worms swarm in the blood-vessels of the skin during the hours of darkness. Between six and seven in the evening they begin to appear in the superficial blood-vessels, and they increase in number until midnight, when they may occur in such numbers that five or six hundred may be counted in a single drop of blood. After midnight, the swarms begin to lessen, and, by breakfast time, about eight or nine in the morning, except for a few strayed revellers, they have disappeared from the superficial circulations, and are hidden away in the larger blood-vessels and in the lungs.

In spite of their incredible number, some authorities place it at thirty to forty millions in one man, these minute larval organisms, shaped something like a needle pointed at each end, seem to cause little harm. It might be thought that they would traverse the walls of the blood-vessels, and cause trouble in the surrounding tissues; but this is prevented by a curious device. It is well known that, like insects, round-worms from time to time cast their skins, and the young larvæ in the blood cast theirs, but do not escape from the inside of this winding-sheet; and thus, though they actively wriggle and coil and uncoil their bodies, their progress is as small, and their struggles as little effective, as are those of a man in a strait-waistcoat.

One reason of the normal appearance of the creatures in the blood at night is undoubtedly connected with the habits of its second host, the gnat or mosquito. Two species are accused of carrying the Filaria from man to man—*Culex fatigans* and *Anopheles nigerrimus.* Sucked up with the blood, the round-worms pass into the stomach of the insect. Here they appear to become violently excited, and rush from one end to the other of their enveloping sheath, until they succeed in breaking through it. When free, they pierce the walls of the stomach of the mosquito, and come to rest in the great thoracic muscles. Here the Filarias rest for some two or three weeks, growing considerably and developing a mouth and an alimentary canal, thence, when they are sufficiently developed, they make their way to the proboscis of the mosquito. Here they lie in couples. Exactly how they effect their exit from the mosquito and their entrance into man has not yet been accurately observed; but presumably it is during the process of biting. Once inside man, they work their way to the lymphatics, and very soon the female begins to pour into the lymph a stream of young embryos, which reach the blood-vessels through the thoracic duct. It is, however, the adults which are the source of all the trouble. They are of considerable size, three or four inches in length; and their presence, by blocking the channels of the lymphatics, gives rise to a wide range of disease, of which elephantiasis is the most pronounced form.

We now pass to the second of the diseases carried by gnats, that of Malaria.

The parasite which causes malaria is a much more lowly organised animal than the Filaria. It is named Hæmamœba, and it too is conveyed by an insect, and, so far as we know, by one genus of mosquito only, the Anopheles. Hence from the point of view of malaria it is important to know whether a district is infected with Culex or Anopheles. The former is rather humpbacked and keeps its body parallel with the surface it is biting, and its larva hangs at an angle below the surface of the water by means of a respiratory tube. Anopheles, on the other hand, carries its body at a sharp angle with the surface upon which it rests, and its larva lies flat below the surface-film and parallel with it. The malarial parasite lives in the blood-cells of man, but at a certain period it breaks up into spores which escape into the fluid of the blood, and it is at this moment that the sufferer feels the access of fever. Their presence and growth within the blood-cells

[1] From an Address delivered before the British Association at Pretoria, by A. E. Shipley, F.R.S.

result in the destruction of the latter, a very serious thing to the patient if the organisms be at all numerous. If the spores be sucked up by an Anopheles, they undergo a complex change, and ultimately reproduce an incredible number of minute spores or sporozoites, each capable of infecting man again if it can but win entrance into his body.

In normal circumstances, for each Filaria larva which enters a mosquito one Filaria issues forth, longer, it is true, and more highly developed, but not much changed. The malaria-parasite undergoes, in its passage through the body of the Anopheles, many and varied phases of its life-history. As the Frenchman said of the pork, which goes into one end of the machine in the Chicago meat-factories as live pig, and comes out at the other in the form of sausages, "il est diablement changé en route."

Whoever has watched under a lens the process of "biting," as carried on by a mosquito, must have observed the fleshy proboscis (labium) terminating in a couple of lobes. The labium is grooved like a gutter, and in the groove lie five piercing stylets, and a second groove or labrum. It is along this labrum that the blood is sucked. Between the paired lobes of the labium, and guided by them (as a billiard cue may be guided by two fingers), a bundle of five extremely fine stylets sinks slowly through the epidermis, cutting into the skin as easily as a paper-knife into a soft cheese. Four of these stylets are toothed, but the single median one is shaped like a two-edged sword. Along its centre, where it is thickest, runs an extremely minute groove, only visible under a high power of the microscope. Down this groove flows the saliva, charged with the spores or germs of the malaria-causing parasite. Through this minute groove has flowed the fluid which, it is no exaggeration to say, has changed the face of continents and profoundly affected the fate of nations.

It is an interesting fact that, amongst the Culicidæ, it is the female alone that bites, and she is undoubtedly greedy. If undisturbed, she simply gorges herself until every joint of her chitinous armour is stretched to the cracking point. At times even, like Baron Munchausen's horse after his adventure with the Portcullis, what she takes in at one end runs out at the other. But she never ceases sucking. The great majority of individuals, however, can never taste blood, and subsist mainly on vegetable juices.

Anopheles is often conveyed great distances by the wind, or in railway trains or ships; but of itself it does not fly far, about five or six hundred yards—some authorities place it much lower—is its limit. Both Anopheles and Culex lay their eggs, as is well known, in standing water, and here three out of the four stages in their life-history—the egg, the larva, and the pupa—are passed through. The larva and the pupa hang on to the surface-film of the water by means of certain suspensory hairs, and by their breathing apparatus. Anything which prevents the breathing tubes reaching the air ensures the death of the larva and pupa. Hence the use of paraffin on the pools or breeding places. It, or any other oily fluid, spreads as a thin layer over the surface of the pools and puddles, and clogs the respiratory pores, and the larvæ or pupæ soon die of suffocation.

Thus a considerable degree of success has attended the efforts of the sanitary authorities, largely at the instigation of Major Ross, all over the world, to diminish the mosquito-plague. It is, of course, equally important to try and destroy the parasite in man by means of quinine. This is, however, a matter of very great difficulty. In Africa and in the East nearly all native children are infected with malaria, though they suffer little, and gradually acquire a high degree of immunity. Still, they are always a source of infection; and Europeans living in malarious districts should always place their dwellings to the windward of the native settlements.

Another elegant little gnat, *Stegomyia fasciata*, closely allied to Culex, with which, until recently, it was placed, is the cause of the spread of that most fatal of epidemic diseases, the yellow fever. Like the Culex, but unlike the Anopheles, Stegomyia has a humpbacked outline, and its larva has a long respiratory tube at an angle to its body, from which it hangs suspended from the surface-film of its watery home. It is a very widely distributed creature; it girdles the earth between the tropics, and is said to live well on shipboard. It breeds in almost any standing fresh water, provided it be not brackish. The female is said to be most active during the warmer hours of the day, from noon until three or so, and in some of the West Indies it is known as the "day-mosquito."

The organism which causes yellow fever has yet to be found. It seems that it is not a bacterium, and that it lives in the blood of man. It evidently passes through a definite series of changes in the mosquito, for freshly infected mosquitoes do not at once convey the disease. After biting an infected person it takes twelve days for the unknown organism to develop in the Stegomyia, before it is ready for a change of host. The mosquitoes are then capable of inoculating man with the disease for nearly two months. The period during which a man may infect the mosquito, should it bite him, is far shorter, and extends only over the first three days of the illness.

Very careful search has hitherto failed to reveal the presence of the parasite of yellow fever. By its works alone can it be judged. It seems that, like the germ of rinderpest and of foot-and-mouth disease, it is ultra-microscopic; and our highest lenses fail to resolve it.

King Solomon sent to Tarshish for gold and silver, ivory, and apes and peacocks, and, at the present day, people mostly go to Africa for gold, diamonds, ivory, and game. These are the baits that draw them in. Of the great obstacles, however, which have for generations succeeded in keeping that great continent, except at the fringes, comparatively free from immigrants, three, and these by no means the least important, are insignificant members of the order Diptera. We have considered the case of Culex and Anopheles; the third fly we have now to do with is the tsetse fly (Glossina), which communicates fatal diseases to man and to cattle and domesticated animals of all kinds.

The members of the genus Glossina are unattractive insects, a little larger than our common house-fly, with a sober brownish or brownish-grey coloration. When at rest the two wings are completely superimposed, like the blades of a shut pair of scissors; and this feature readily serves to distinguish the genus from that of all other blood-sucking flies, and is of great use in discriminating between the tsetse and the somewhat nearly allied Stomoxys and Hæmatoputa.

The tsetse flies rapidly and directly to the object it seeks, and must have a keen sense of smell, or sight, or both, making straight for its prey, and being most persistent in its attacks. The buzzing which it produces when flying is peculiar, and easily recognised again when once heard. After feeding, the fly emits a higher note, a fact recalling the observation of Dr. Nuttall and the present writer on the note of Anopheles, in which animal we observed that "the larger the meal the higher the note." The tsetse does not settle lightly and imperceptibly on the sufferer as the Culicidæ do, nor does it alight slowly and circumspectly after the manner of the horse-flies, but it comes down with a bump, square on its legs. Like the mosquito, the tsetse is greedy, and sucks voraciously. The abdomen becomes almost spherical, and of a crimson red, and in the course of a few seconds the fly has exchanged the meagre proportions of a Don Quixote for the ampler circumference of a Sancho Panza. Unlike so many of the blood-sucking Diptera, in which the habit is confined to the females, both sexes of Glossina attack warm-blooded creatures.

The fly always seems to choose a very inaccessible portion of the body to operate on, between the shoulders in man, or on the back and belly in cattle and horses, even inside the nostrils in the latter, or on the forehead in dogs. According to Lieut.-Colonel D. Bruce, R.A.M.C., to whom we owe so much of our knowledge of this fly and its evil work, the female does not lay eggs, but is viviparous, and produces a large active yellow larva, which immediately crawls away to some secluded crevice, and straightway turns into a hard, black pupa, from which the imago emerges in some six weeks. Thus two stages, the egg and the larva, both peculiarly liable to destruction, are practically skipped in the tsetse, at any rate in some species.

The genera of the Culicidæ which we have considered are found practically all over the world, but the genus

Glossina is fortunately confined to Africa. From the admirable map of the geographical distribution of the fly compiled by Mr. Austen, we gather that its northern limit corresponds with a line drawn from the Gambia, through Lake Chad to Somaliland, somewhere about the thirteenth parallel of north latitude. Its southern limit is about on a level with the northern limit of Zululand. The tsetse, of course, is not found everywhere within this area; and, though it has probably escaped observation in many districts, it seems clear that it is very sporadically distributed.

Even where the tsetse is found, it is not uniformly distributed, but occurs in certain localities only. These form the much dreaded "fly-belts." The normal prey of the fly is undoubtedly the big game of Africa. But they are not the only factor in its distribution. The nature of the land also plays a part. There are the usual discrepancies in the accounts of travellers, especially of African travellers, as to the exact localities the Glossina affects; but most writers agree that the tsetse is not found in the open veldt. It must have cover. Warm, moist, steamy hollows, containing water and clothed with forest growth, are the haunts chosen.

The tsetse fly belongs to the family Muscidæ, the true flies, a very large family, which also includes our house-fly, blue-bottle fly, &c. These flies, unlike Anopheles and Culex, are day-flies, and begin to disappear at or about sunset, a fact noted centuries ago by Dante:—

> "Nel tempo che colui, che il mondo schiara,
> La faccia sua a noi tien meno ascosa,
> Come la mosca cede alla zanzara."[1]

The practical disappearance as the temperature drops has enabled the South African traveller to traverse the fly-belts with impunity during the cooler hours of the night. At nightfall the tsetse seems to retire to rest amongst the shrubs and undergrowth; but, if the weather be warm, it may sit up late; and some experienced travellers refrain from entering a fly-belt, especially on a summer's night, until the temperature has considerably fallen.

The sickness and death of the cattle bitten by the tsetse were formerly attributed to some specific poison secreted by the fly, and injected during the process of biting. It is now, largely owing to the researches of Colonel Bruce, known to be due to the inoculation of the beasts with a minute parasitic organism conveyed from host to host by the fly. The disease is known as "nagana," and the organism that causes it is a species of Trypanosoma, a flagellate protozoon or unicellular organism, which moves by means of the lashing of a minute, whip-like process. Since Bruce's researches, a number of Trypanosomas have been found causing disease in various parts of the world; thus *T. evansii* causes the surra disease of cattle, horses, and camels in India; *T. equinum* produces the "mal de caderas" of the horse ranches of South America; and *T. equiperdum* is responsible for the North African disease called by the French the dourine; *T. theileri* causes the gall-sickness, and there are others. The particular species of Trypanosoma which causes nagana is *Trypanosoma brucei*, and it does not attack man; goats and donkeys seem also immune; but, with these exceptions, all domesticated animals suffer, and in a great percentage of cases the disease terminates in death. Just as the native children in Africa form the source of the supply of the malarial parasite without appearing to suffer much, so do the big game of the country abound in Trypanosoma without appearing to be any the worse. They are in Lankester's phrase "tolerant" of the parasite, and a harmony between them and the parasite has been established, so that both live together without hurting one another. It is from the big game that the disease has spread. In their bodies the harmful effect of the parasite has, through countless generations, become attenuated; but it leaps into full activity again as soon as the Trypanosoma wins its way into the body of any introduced cattle, horse, or domesticated animal.

The report of Colonel Bruce, which has just been issued, shows that the sleeping sickness which devastates Central Africa, from the west coast to the east, is also conveyed by a species of tsetse fly. Writing more than a hundred years ago of Sierra Leone, Winterbottom mentions the disease. "The Africans," he says, "are very subject to a species of lethargy which they are very much afraid of, as it proves fatal in every instance." Early last century it was recorded in Brazil and the West Indies; and Lankester has suggested that the deaths which our slave-owning ancestors used to attribute to a severe form of home-sickness, or even to a broken heart, were in reality caused by sleeping sickness. In one year the deaths in the region of Busoga reached a total of 20,000; and it is calculated that although the disease was only noticed in Uganda for the first time in 1901, by the middle of 1904 100,000 people had been killed by it. The disease is caused by the presence of a second species of Trypanosoma in the blood and in the cerebro-spinal fluid. The existence of this parasite has now been proved in all the cases recently investigated. Apparently the Trypanosoma can live in the blood without doing much harm, and only when it reaches the cerebro-spinal canal does it set up the sleeping-sickness. It is also found in great numbers in the lymphatic glands, especially those of the neck, which in patients infected by the parasite are usually swollen and tender. From the similarity of the parasite to that causing the cattle disease of South Africa, the idea at once arose that the Trypanosoma was conveyed from man to man by a biting insect. Along the lake shores a species of tsetse (*G. palpalis*) abounds; and it was noticed that if the fly, having fed off a sleeping-sickness patient, bit a monkey, the monkey became infected. Further, flies which were captured in a sleeping-sickness district were also capable of conveying the disease to healthy monkeys. The proof that sleeping sickness is due to a Trypanosoma known as *T. gambiense* present in the cerebro-spinal fluid of the patient, due to the brilliant research of Colonel Bruce and his colleagues, Captain Grieg and Dr. Nabarro, and that it is conveyed from man to man by *Glossina palpalis*, seems now complete.

Finally, we come to a last class of diseases which is of the utmost interest to the agriculturist and settler, and yet at present is but little understood. These diseases are caused by various species of a protozoon named Piroplasma, and the diseases may collectively be spoken of as piroplasmosis. When they are present in cattle they are spoken of in various parts of the world as Texas fever, tick-fever, blackwater, and redwater. Heartwater in sheep is a form of piroplasmosis. Horses also suffer, and the malignant jaundice or bilious fever which makes it impossible to keep dogs in certain parts of this country is also caused by a Piroplasma. Finally, under the name of Rocky Mountain fever, spotted- or tick-fever, the disease attacks man throughout the west half of the United States.

The organisms which cause the disease live for the most part in the red blood corpuscles, but they are sometimes to be found in the plasma or liquid of the blood. Unfortunately we know comparatively little about the life-history of the Piroplasma or of the various stages it passes through, but we do know how it is transmitted from animal to animal and from man to man.

We have seen that the carrier or "go-between" in the case of the malaria is the mosquito, and in the case of the sleeping sickness is the tsetse fly. Piroplasma, however, is not conveyed from host to host by any insect, but by mites or ticks, members of the large group of Acarines, which include beside the mites the spiders, scorpions, harvestmen, and many others.

The ticks differ from the insect bearers of disease, inasmuch as the tick that attacks an ox or a dog does not itself convey the disease, but it lays eggs—for I regret to say here, as with the Anopheles, it is the female only that bites—and from these eggs arises the generation which is infective, and which is capable of spreading the disease. The tick which conveys the Piroplasma from dog to dog is called *Haemophysalis leachi*. The brilliant researches of Mr. Lounsbury have shown that even the young are not immediately capable of giving rise to the disease. The female tick gorges herself with blood, drops to the ground, and begins laying eggs. From these eggs small six-legged larvæ emerge. These larvæ, if they get a chance, attach themselves to a dog, gorge themselves, and after a couple of days fall off. If their mother was infected they nevertheless do not convey the parasite. After lying for a time upon the ground the larval tick casts its skin and becomes

[1] *Inf.* xxvi. 26–28.

a nymph, a stage roughly corresponding with chrysalis of a butterfly. This nymph, if it has luck, again attaches itself to the dog and has a meal, but it also fails to infect the dog. After a varying time it also drops to the ground, undergoes a metamorphosis, and gives rise to the eight-legged adult tick. Here at last we reach the infective stage; the adult tick is alone capable of giving the disease to the animal upon which she feeds, and then only when she is descended from a tick which has bitten an infested host. Think what a life-history this parasite has! Living in the blood-corpuscles of a dog, sucked up by an adult tick, passed through her body until it reaches an egg, laid with that egg, being present while the egg segments and slowly develops into the larva; living quiescent during the larval stage and the nymph stage, surviving the metamorphosis, and only leaping into activity when the adult stage is reached. This most remarkable story probably indicates that the Piroplasma undergoes a series of changes comparable to those of the malaria organism when it is inside the mosquito; what these stages are we do not at present know, but Dr. Nuttall and Mr. Smedley at Cambridge, and many other observers elsewhere, are at work on the problem, and soon we shall have more light.

With regard to bovine piroplasmosis, Koch and others have distinguished redwater fever, which is conveyed by *Rhipicephalus annulatus*, and in Europe probably by *Ixodes reduvius* from the Rhodesian fever which is conveyed by *Rhipicephalus appendiculatus*, and I regret to say by a species dedicated to myself, *Rhipicephalus shipleyi*.[1]

The heartwater disease of sheep and goats is similarly conveyed by *Amblyomma hebraeum*, the Bont tick, and many farmers accuse *Ixodes pilosus* of causing the well known paralysis from which sheep suffer in the early autumn; and there are many others, diseases such as the chicken disease of Brazil, which is so fatal to poultry yards, and which is conveyed by the *Argas persicus*.

I will not weary you with more diseases. I think I have said enough to show that within the last few years a flood of light has been thrown upon diseases, not only of man and his domestic animals, but upon such insignificant creatures as the mosquito and the tick. I have tried to show how these diseases interact, and how both hosts are absolutely essential to the disease. We can now to a great extent control these troubles; the old idea that there is something unhealthy in the climate of the tropics is giving way to the idea that the unhealthiness is due to definite organisms conveyed into man by definite biting insects. We have at last, I think, an explanation of why Beelzebub was called the Lord of Flies.

[1] This happily turns out to be a synonym.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Prof. Osler has been nominated by the Vice-Chancellor and Proctors as a delegate of the University Press.

A decree has been approved by Convocation providing that the stipend of the Sibthorpian professor of rural economy shall be 600*l.* a year, independently of the income from the Sibthorpian estate, in the years 1906 and 1907. This is necessary if an election is to be made before 1908, as the full endowment will not be provided by St. John's College until that year. St. John's is to nominate a member of the board of electors to the chair.

The following elections have been made to scholarships and exhibitions in natural science:—Balliol College, to a Brakenbury scholarship, J. S. Huxley (Eton College), to a scholarship, C. Whitley (Bromsgrove School); Lincoln College, to a scholarship, P. Pickford (Exeter School), to an exhibition, E. Hancock (Exeter School); Magdalen College, to a demyship, D. L. Hammick (Whitgift Grammar School, Croydon), to an exhibition, J. F. Venables (Magdalen College School, Oxford); Christ Church, to a scholarship, J. T. Lattey (Dulwich College), to an exhibition, W. A. Akers (Aldenham School); Trinity College, to a Millard scholarship, H. G. J. Moseley (Eton College).

A COURSE of lectures upon modern research in the psychology of memory, accompanied by the exhibition of apparatus, will be given by Dr. C. S. Myers in the physiological theatre of King's College, London, on January 12 and the following seven Fridays at 6 p.m. The course is free to internal students of the university and to all teachers. The general course in experimental psychology, accompanied by laboratory work, will be held on Saturdays, beginning on January 13. Particulars may be obtained from the secretary of the college.

THE *London University Gazette* announces that a course of nine or ten lectures on the origin of Gymnosperms will be given during the Lent term by Prof. F. W. Oliver, F.R.S., at University College on Mondays, commencing on January 22. There is no fee for the lectures. Further details and cards of admission may be obtained on application to the academic registrar at the university. Two courses of lectures have been arranged for the Lent term in the physiological laboratory of the university, viz. eight lectures on tissue-respiration by Mr. J. Barcroft on Tuesdays, beginning on January 16, and eight lectures on respiration by Dr. M. S. Pembrey on Fridays, beginning on January 19.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 23, 1905.—"Some Observations on *Welwitschia mirabilis*, Hooker, f. By Prof. H. H. W. **Pearson.** Communicated by A. C. Seward, F.R.S.

Evidence is adduced in support of the view that Welwitschia is partially, if not entirely, insect-pollinated, and that the processes of fertilisation and maturation of the seed seem to be effected much more rapidly than in other Gymnosperms.

The author supports Strasburger's view that the male flowers are reduced forms of an originally hermaphrodite structure. The nature of the prothallial tubes is discussed, and the conclusion is that the true interpretation of the extraordinary behaviour of the fertile end of the Welwitschia prothallus will be founded upon a comparison with the corresponding portion of the embryo-sac of *Gnetum gnemon*.

December 14, 1905.—"The Araucarieæ, Recent and Extinct." By A. C. **Seward,** F.R.S., and Sibille O. **Ford.**

The work was undertaken primarily with a view to ascertain whether the genera Agathis and Araucaria exhibit any of those features which are often associated with survivals from the past; the aim was to obtain an answer to the question: Do the existing Araucarieæ afford evidence of primitive characters or do they throw light on the phylogeny of the araucarian phylum?

A comparison is made between the Araucarieæ and Lycopodiales; arguments are advanced in favour of the view that this group of Gymnosperms, unlike the Cycadales, was probably derived from lycopodiaceous ancestors. Attention is directed to the various characters in which the Araucarieæ differ from other members of the Coniferales, and the advisability is suggested of giving more definite expression to their somewhat isolated position by substituting the designation Araucariales for Araucarieæ.

The authors contend that the general consent which has deservedly been given to the view that the Cycadales and Filicales are intimately connected by descent may have the effect of inducing an attitude too prone to overestimate the value of the arguments advanced in support of an extension of the idea of a filicinean ancestry to other sections of the Gymnosperms.

"On the Microsporangia of the Pteridosperms." By R. **Kidston,** F.R.S.

The conclusion arrived at is that the Cycadofilices, which long antedated the advent of true ferns, cannot have been derived from them, but are themselves the oldest type of fern-like plant at present known. In regard to the true ferns, it seems probable that they may have been derived from the Botryopterideæ.

"The Mammalian Cerebral Cortex, with Special Reference to its Comparative Histology. I., Order Insectivora." By Dr. G. A. **Watson.** Communicated by Dr. F. W. Mott, F.R.S.

This paper is one of a series in which it is hoped to deal with the cerebral cortex of the various orders of mammals so far as material is available, the primary object of the research being to endeavour to shed some further light upon the significance of the mammalian neopallial lamination. In this natural order the brains of the mole (*Talpa europea*), shrew (*Sorex vulgaris*), and hedgehog (*Erinaceus europeus*) have been exhaustively studied.

The neopallium of these animals has been mapped out into various areas, which on the dorso-lateral and mesial aspects appear to present (1) "motor," (2) general sensory, and (3) undifferentiated or unspecialised characteristics, the two former being in every way the best developed neopallial regions. On the postero-mesial aspect a field has been delimited which possesses sensory features; a portion of this is unspecialised, and the remainder is believed to represent the cortical distribution of the optic and fifth sensory nerves respectively. Certain differences in the extent and state of development of these various areas occur in the several animals, and these agree with certain differences in their habits.

The total depth of the cortex in the best developed regions differs in the three animals, yet the relative depth of the separate layers is about the same in all. Micrometric measurements of the cortex of the mole have been made by Dr. Bolton, and these have been compared with the latter's measurements of the cortical layers in the developing human fœtus and the normal human adult. Dividing the cortex into the portions above and below the granular layer, it is found that the increase in depth of the human cortex as compared with that, say, of the mole is *very* largely due to increase in the "*supra-granular*" (*i.e.* the true pyramidal) layer.

The conclusions as to the functional significance of the neopallial primary cell layers in the Insectivora and in mammals belonging to other natural orders so far examined form a complement to those advanced by Bolton. The "*infra-granular*" layer (iv. and v.), omitting the constituent cells which possess motor or analogous functions, is concerned especially with the associations necessary for the performance of the instinctive activities, the "supra-granular" (ii.) with the higher associations ("intelligence"), the capacity for which is shown by the educability of the animal. In practical animal behaviour the two sets of processes are probably more or less constantly interwoven, the higher activities (supra-granular layer) coming to the aid of the lower so far as the capability of the animal allows. In the case of lower mammals, *e.g.* Insectivora, the limits of this capability are comparatively soon reached, and correspondingly these mammals possess a relatively poor "supra-granular" layer.

Anthropological Institute, December 19, 1905.—Prof. W. Gowland, president, in the chair.—The origin of Eolithic flints from natural causes: S. H. **Warren**. Mr. Warren classified eoliths as follows:—(1) Flints with battered surfaces formed by prolonged concussions; (2) flints with flaked surfaces formed by sharp percussions; (3) flints with chipped edges formed by (*a*) indiscriminate battering, (*b*) perpendicular pressure. The possible causes of the production of eoliths were considered by Mr. Warren to be:—(*a*) human agency; (*b*) wave action; (*c*) water abrasion by streams, rivers, floods; (*d*) soil abrasion by the pressure and movement of soil creep and foundering; (*e*) the drag of ice; and (*f*) wear and tear on the surface of the ground. The eoliths of the first class, as defined above, may obviously be due to water abrasion. Those of the second class bear evidences of percussion-flaking, acting along the lines of least resistance, but show no control-working upon a definite design. It is concluded that these forms, together with those having indiscriminately battered edges, are likewise due to water abrasion. It is noteworthy that these classes are characteristic of river gravels of various ages, and may be reproduced by artificial rolling. The flints with definitely pressure-chipped edges include the typical "plateau implements" of Sir J. Prestwich. The chief forms are a general chipped edge, and the notch, either single or in various combinations, such as the double notch with intervening point. It is found by experiment that these are the forms produced by the fortuitous pressure of one flint against another. The angle of chipping and the type of the fractures are also identical in the case of the experimental productions and the plateau flints. These pressure-chipped eoliths are characteristic of hill-drifts which have suffered from the movement of soil-creep and foundering, and it is concluded that this is the cause of the chipped edges. This process is named "soil abrasion" in contradistinction to water abrasion. Collateral evidence of these differential soil movements under pressure is furnished by the frequent association with the eoliths of the hill-drifts of flints with surfaces striated in all directions. Subsidiary causes of the pressure-chipped eoliths, or those which have operated in certain special cases, are the drag of ice and wear and tear on the surface of the ground, including the impact of the hoofs of animals.

EDINBURGH.

Royal Society, December 4, 1905.—Lord Kelvin, president, in the chair.—The development of the skull and visceral arches in Lepidosiren: W. E. **Agar**. The material for this investigation had been collected by Prof. Graham Kerr in the Chaco, and by the late Mr. J. S. Budgett in the Gambia. The chief points established were as follows:—The development of the notochord underwent a curious modification, the front end disintegrating at an early stage and being replaced by a forward growth of the remaining part of the chorda. The quadrate was from the first continuous with the trabecula, and there was no hyomandibular. A vestigial palato-pterygoid bar was present. The general development of the skull resembled the process in the Urodeles, especially as regards the occipital region and nasal capsules. There were two pairs of upper labial cartilages. In the change from the larval to the adult form there was no absorption of cartilage, but the chondrocranium showed a steady increase in completeness.—Perturbations in longitude of Neptune by the hypothetical planet: Prof. George **Forbes**, F.R.S. About twenty-five years ago the author had deduced evidence from the distribution of the aphelia of cometary orbits that there existed a planet of considerable mass beyond the orbit of Neptune, and the existence of such a planet was now generally accepted by astronomers. In the present paper, by means of calculations based upon certain assumptions as to position and mass of the hypothetical planet, Prof. Forbes discussed the growing discrepancies between the observed longitudes of Neptune and those assigned by the theories both of Leverrier and Newcomb. The present configuration of the two planets was not the best to bring out clearly the nature of the perturbation, but he thought that in ten years sufficient material would be in hand to enable us to make a serious effort to fix the position of the ultra-Neptunian planet. Exhibition of two lantern slides of zoological interest: Prof. D. J. **Cunningham**, F.R.S. The one showed a group of monkeys in the Dublin Zoological Gardens sitting in newly fallen snow without the least discomfort; from the beginning of their captivity they had lived in the open air. The other showed a young marmoset clinging in its peculiar fashion to the back of a white rabbit which had acted as foster-mother from the start of the marmoset's individual life.

December 18, 1905.—Dr. R. H. Traquair, F.R.S., vice-president, in the chair.—Library aids to mathematical research: Dr. Thomas **Muir**, F.R.S. After a critical discussion of the various bibliographical aids to the mathematical student, the author proceeded to point out the shortcomings in the equipment of the most important scientific libraries in Edinburgh and Glasgow. Out of sixty-seven important mathematical serials, only thirty-four were to be found in Edinburgh and Glasgow; and of the thirty-one to be found in Edinburgh, twenty-one were duplicated in the university and Royal Society libraries. Dr. Muir hoped that by some system of cooperation between the Edinburgh libraries, or even between Edinburgh and Glasgow, every mathematical serial published in Europe and America would be made available to mathematical workers. At present historical research was absolutely debarred.—Preliminary note regarding an experimental investigation into the effects of varying diets upon growth and nutrition: Dr. Chalmers **Watson**. The experiments consisted in feeding colonies of rats upon various diets, namely, (1) skim milk and bread; (2) rice;

(3) porridge; (4) horse flesh; (5) ox flesh. Interesting details were given and illustrated by diagrams and tables. The rats were found to thrive best on the skim milk and bread. Rice, because of its lack of proteid qualities, stunted the growth. Porridge was inferior to the skim milk and bread, while horse flesh and ox flesh were positively deleterious, being fatal to young rats. Moreover, the mortality among the young was greatly increased when the adult parents were fed on flesh. Experiments were also tried on the effects of change of diet. For example, after the young rats had been reduced almost to starvation point by a flesh diet, they were put on milk and bread, and immediately began to recover, and rapidly reached the maximum growth. In this set of experiments it was found that sweet milk and bread were inferior as a recuperative diet to skim milk and bread. Prof. Schäfer, in whose laboratory the experiments had been carried out, referred to the importance of the research in relation to physical deterioration. Although it would be absurd to apply the results directly to the question of human diets and nutrition, there was no doubt that the physical deterioration so much spoken about was due, not only to underfeeding, but to wrong feeding. So far as the public was concerned, the moral was that we must feed our children correctly.

NEW SOUTH WALES.

Royal Society, October 4, 1905.—Mr. H. A. Lenehan, president, in the chair.—Note on some simple models for use in the teaching of elementary crystallography: Dr. W. G. **Woolnough**. The models illustrated the connection between the number of faces in a crystal "form" and the elements of symmetry of the group to which the crystal belongs. Planes of symmetry are represented in the models by mirrors suitably arranged, and crystal faces by triangles of cardboard. The mirrors are so fixed that the multiple reflection of the card reproduces the shape of the most general form possible in the crystal group.

November 1, 1905.—Mr. H. A. Lenehan, president, in the chair.—Provisional determination of astronomical refraction, from observations made with the meridian circle instrument of the Sydney Observatory: C. J. **Merfield**. This paper gives the results of an investigation into astronomical refraction, deduced from some five hundred and fifty observations of forty fundamental stars taken with the meridian circle of the Sydney Observatory during the month of July, 1905. The conclusions arrived at by the author are as follows:—That if observations of zenith distance of celestial objects are taken between limits of time separated by some hours, then greater accuracy in the reductions, to obtain correct positions, can be obtained by taking fully into consideration the fluctuations of the height of the barometer, and especially the variation of the temperature, indicated by the readings of the thermometer, when computing the refractions for a series of observations extending over a period of several hours' duration. Adopting a state of the atmosphere for a mean of the times of observation does not seem sufficient. Further, the refraction table (Bessel) in use at the Sydney Observatory would represent the observed refractions much better if a correction be applied for the difference in the force of gravity at Greenwich and Sydney. This correction is represented by a very simple equation which is a function of the latitudes of the two places. The author also considers that the refractions computed from the Pulkowa tables, after applying the gravity correction, would represent the observed values better than those of Bessel.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 4.

RONTGEN SOCIETY, at 8.15.—Presidential address: The Present Position of Radio-activity: Prof. F. Soddy.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY, at 8.—The Present Position of the Sewage Question: J. F. Reade.

FRIDAY, JANUARY 5.

GEOLOGISTS' ASSOCIATION, at 8.—On the Geology of the Country around the Sogne Fjord and the Hardanger Fjord, Norway: H. W. Monckton.

MONDAY, JANUARY 8.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Cinchona Barks and their Cultivation: D. Howard.—A New Method for the Quantitative Estimation of Acetone: S. J. M. Auld.

TUESDAY, JANUARY 9.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Elimination of Stormwater from Sewerage Systems: D. E. Lloyd-Davies.—On the Elimination of Suspended Solids and Colloidal Matters from Sewage: Lieut.-Colonel A. S. Jones and Dr. W. O. Travis.

WEDNESDAY, JANUARY 10.

GEOLOGICAL SOCIETY, at 8.—The Clay-with-Flints: its Origin and Distribution: A. J. Jukes-Browne.—On Footprints from the Permian of Mansfield (Nottinghamshire): G. Hickling.

THURSDAY, JANUARY 11.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Charing Cross Company's City of London Works: W. H. Patchell (*Conclusion of Discussion*).

LONDON MATHEMATICAL SOCIETY, at 5.30.—On the Diffraction of Sound by Large Cylinders: J. W. Nicholson.—On the Monogeneity of an Algebraic Function: Dr. H. F. Baker.

FRIDAY, JANUARY 12.

ROYAL ASTRONOMICAL SOCIETY, at 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Lecture on the Theory of Machines: Prof. J. D. Cormack.

MALACOLOGICAL SOCIETY, at 8.—Note of the Dates of Publication of C. L. F. von Sandberger's "Die Land- und Süsswasser-conchylien der Vorwelt," 1870–75: B. B. Woodward.—New Species of Siphonaria, Terebra, and Maugilia, and a Remarkable Form of *Cypraea cruenta*, from South Africa: G. B. Sowerby.—Remarks on some Forms of Chloritis with Description of a New Species: G. K. Gude.—Notes on the Anatomy of S. African Aplysiidæ with Descriptions of two New Species: R. H. Burne.—Notes on *Voluta kenyoniana*, *V. papillosa* var. *costata*, *V. readknighti*. Juv., *Cypraea tigris*. var. *lineata*, and *Conus waterhousae*, var. *mauritiana*: Mrs. Kenyon. Description of a New Species of Crepidula from Victoria: Mrs. Kenyon.

THURSDAY, JANUARY 11, 1906.

THE EQUATIONS OF THE WAVE THEORY.

The Analytical Theory of Light. By J. Walker. Pp. xv+416. (Cambridge: The University Press, 1904.) Price 15*s.* net.

MR. WALKER has written a valuable book, but one difficult to review. As he says in his first sentence:—

"The Science of Physical Optics may be regarded as comprising two fields of enquiry; the one includes the study of the physical properties of a stream of light, the other comprehends the investigation of the Mechanism by means of which the stream is propagated. These two divisions may be called respectively the kinematics and the dynamics of the subject."

It is with the first of these that Mr. Walker is concerned; a few experimental facts suffice to show that a stream of light may be represented by a periodically varying vector, transverse to the beam, and on this result, with an appeal where necessary to experimental facts, the treatment of the subject is based.

The appeal to experiment is made as rarely as possible, and as a result we have a book dealing with a physical subject which is almost entirely pure mathematics. Such a book has its value, and in this the value is a high one, for the author has discharged the task he set himself in an admirable manner; but owing to his severe restraint the book lacks interest and its difficulty is increased. It is not a text-book of physical optics, but of the analytical theory of light; the light vector satisfies certain differential equations, and the consequences of this are traced out with a rare degree of completeness. It is a book to which students who desire to know how far the mathematical side of the wave theory has been carried, what are its limitations, and in what directions advances are possible will usefully turn. This knowledge is necessary for the physicist who is more interested in the dynamical theory, for, as Mr. Walker points out, it forms the touchstone on which optical theories are tried, and no one theory of the ether can at present be said to hold the field. No doubt the introduction of even the salient points of the various theories might have had the effect which the author fears of veiling his main purpose; still, the restraint which he has laid on himself has its disadvantages.

Starting with the ordinary geometrical propositions of the wave theory, we come in the second chapter to a discussion of Michelson's experiments and the recent work on the nature of white light; the properties of the polarisation vector are deduced from the non-interference of two beams polarised in planes at right angles. In connecting together the intensity of a beam of light and the amplitude of the polarisation vector, a difficulty is at once met with unless we know the relation between the energy of the stream and the amplitude. For this purpose we require to determine the nature of the vector, and this it is impossible to do without advancing a theory of the mechanism of the transmission, a course which is closed to us. However, the assumption that the square of the polarisation vector measures the intensity is shown to lead to consistent results, and this assumption is made.

The analytical theory really begins in chapter v. with the differential equations of the polarisation vector; the previous discussion has enabled us to express this in the form of a function of $vt-r$, where v is the velocity of propagation, and from these the differential equations are deduced in the usual form, and the important result that when the wave velocity is independent of the period any singularity of phase or amplitude travels with the speed of the wave is shown to follow by a method of proof due to Poincaré; Lord Rayleigh's generalisation in the case when the velocity is a function of the period follows.

Reference had been made in an earlier chapter to Huyghens's principle and its connection with the rectilinear propagation of light; the full proof of the principle depending on the relation at any point within a surface S between a function ϕ_0 satisfying $d^2\phi/dt^2=w^2\nabla^2\phi$ and a certain surface integral taken over the surface of S is then discussed, leading us to Stokes's well known law of the secondary disturbance due to a wave of light, and also to an expression for the disturbance in the neighbourhood of a screen producing diffraction. Fraunhofer's diffraction phenomena are first discussed here; the more complicated cases known as Fresnel's, in which the screen is not at the focus of the light forming the diffraction pattern, follow. The treatment is based on that of Lommel, and deals fully with a rectangular aperture or obstacle, a straight edge, Fresnel's biprism, and a circular aperture and disc. The treatment of the biprism follows Struve and Weber's work.

In chapter ix. an account of some quite recent work by Sommerfeld, Poincaré, and Macdonald dealing with the application of spherical harmonics to diffraction phenomena is given, and after this a short account of Newton's rings and of the laws of reflection and refraction leads to double refraction. For uniaxial crystals the theory is based on Huyghens's assumption, first satisfactorily verified by Stokes, that the wave surface consists of a sphere and a spheroid which touch at the extremities of the axis of the latter, while for biaxial crystals all the laws are deduced from Fresnel's polarisation ellipsoid, a surface which has the property that the velocities of propagation of any wave are equal to the reciprocals of the axes of the section of the ellipsoid by a plane parallel to the wave. Hence the form of the wave surface and the laws of double refraction follow in the usual way.

Chapter xii. contains a number of results on the wave surface which are not easily found elsewhere; in dealing with reflection at a crystal surface, the equations of the polarisation vector in a crystal are first formed, and then the surface conditions are deduced. Free use is made of MacCullagh's ingenious device of uniradial directions. The discussion of the inter-

M

ference of polarised light follows a normal path, but the part relating to biaxial crystals is unusually full. The later chapters deal with absorbing media, dispersion, structurally active media, and magnetically active media; each of these phenomena is shown to follow from suitable modifications in the expression for the light vector; the interesting question of the constitution of the ether which could give rise to such modifications is, of course, in the author's scheme passed by. But while this is necessarily the case, the analysis given is very full and complete, and Mr. Walker has added to the literature of the subject a book of real value. The book has been printed at the Cambridge Press and published by the Syndics, and their share of the work is admirable.

LIQUID CRYSTALS.

Kristallinische Flussigkeiten und flussige Kristalle. By Rudolf Schenck. Pp. viii+158. (Leipzig: Wilhelm Engelmann, 1905.)

THE announcement of the discovery of liquids that were doubly refracting and dichroic by Prof. Lehmann some fifteen years ago was received with considerable mistrust, for the possession by a liquid of these properties which had hitherto been associated solely with the solid crystalline state seemed at first sight almost inconceivable, and quite inconsistent with the generally accepted ideas as to the molecular tactics of liquids and crystals. The very name of liquid crystal seemed to be self-contradictory. Lehmann's results, however, were soon confirmed by other physicists, one of the most active amongst whom was Dr. Schenck, the writer of the present work on the subject.

Several explanations of Lehmann's observations were offered, based on the assumption that he had worked with liquids containing impurities. Quincke supposed them to consist of solid crystalline particles surrounded by a film of liquid, and Tammann endeavoured to explain their properties by assuming them to be an emulsion of two liquid phases. On the other hand, Lehmann pointed out that it was not justifiable to consider these cases as if they were isolated instances of irregular properties, since the behaviour of these liquids apparently so anomalous may be reconciled with that of other crystalline media if we consider the part played by the rigidity of crystals in maintaining their crystalline form. His investigations have shown that the rigidity of different crystals varies within wide limits. The majority of those we know best offer considerable resistance to deformation, while some, like yellow phosphorus, are quite soft, and others, such as the oleates, have so little rigidity that the force of surface tension is sufficient to deform the crystal from its true geometrical shape; in the limiting case, that of *p*-azoxyanisol and the other liquids investigated by Lehmann, the rigidity has become so small compared with the force due to surface tension that the crystal when placed in a liquid of equal density assumes a spherical form.

Lehmann's work was entirely microscopic, but macroscopic investigations were undertaken by other investigators. A study of the physical properties of the birefringent liquids, particularly of their viscosity and dielectric constants, and an unsuccessful attempt to resolve them by cataphoresis, showed that each of them was without doubt a single substance, and thus the hypotheses put forward by Quincke, Tammann, and other authors were disproved.

Prof. Lehmann's monograph on these bodies, which was reviewed in NATURE recently (vol. lxx., p. 622, 1904), consists mainly of an account of the results of his microscopic investigations and of the theory he has formulated to explain these. A very important part of the work was thus left undescribed, and Dr. Schenck's book covers the ground omitted by Lehmann, and, in addition, gives a short summary of the latter's experiments.

The preparation of the various substances that have been found to yield anisotropic liquids is described in detail, also the determination of their physical constants. The investigation of the surface energy of the liquids indicates that there is no sudden change in their molecular weight at the temperature at which the anisotropic liquid passes into the isotropic condition. The viscosity curves, however, show a large break at this temperature, the isotropic liquids being in some cases the more viscous. The density curves show a similar discontinuity. The two liquids have different specific heats, and there is a small but definite heat of transformation of one form to the other.

Dr. Schenck has given a very complete account of our knowledge of these anomalous liquids, which have great interest both for the chemist and physicist, and his book will be of great service to those who wish for information about them. It is clearly written and arranged, and contains a number of diagrams and plates. Of theories as to their nature he wisely fights very shy, and it seems that considerably more work is needed before we shall be able to form any clear idea as to their molecular structure.

H. B. H.

PLANT-BREEDING IN AMERICA.

New Creations in Plant Life: an Authoritative Account of the Life and Work of Luther Burbank. By W. S. Harwood. Pp. xiv+368; 50 illustrations. (New York: The Macmillan Company; London: Macmillan and Co., Ltd.) Price 7s. 6d. net.

THERE is something to be said in favour of this work; at the same time we imagine no one will have more cause to regret its appearance than Mr. Burbank himself. The reasons for this expression of opinion are easily supplied. It is decidedly desirable that the outside public should be made aware of the enormous practical importance of what is called plant-breeding, and that they should be familiarised with the means and methods adopted by experts for the multiplication and improvement of flowers, fruits, and other vegetable products. A slightly increased percentage of sugar in the sugar-cane or the beet, an apparently trifling improvement in the staple of

cotton, the development of a potato relatively immune to fungous diseases, an increased production of fruit or the introduction of hardier varieties, of some that are earlier, of others that are later, to say nothing of the improvement of flowers in form, colour, and perfume, are all points of great importance and of very great interest from a biological point of view.

In this field of work Mr. Burbank has long been known as an energetic labourer, and it is quite possible that in actual amount his work bulks larger than that of any of his predecessors or his contemporaries. Moreover, as we learn from the book before us, and from other sources, the experimenter is a man of high purpose, modest, and amiable. It is for these personal reasons we imagine that he will have cause to regret the appearance of this volume. We have no desire to belittle Mr. Burbank or to undervalue the importance of what he has accomplished. We believe that he would be the first to acknowledge that there existed strong men previous to the appearance of Agamemnon. But this is a fact that his eulogist does not sufficiently estimate. In perusing the glowing paragraphs of this volume the casual reader might imagine that there were no plant-breeders before Burbank, or that their labours were comparatively insignificant, and yet in our own country alone we seem to have heard of Thomas Andrew Knight, of Dean Herbert, of Trevor Clarke, of Thomas Rivers, of John Laing, of Dominy, of Seden, of Laxton, and of a large number of others whose productions at least vie in importance with those of the American experimenter, whilst a visit to the great establishments of Vilmorin, near Paris, Benary, and others at Erfurt and Quedlinburg, as well as to the trial-grounds of our Veitchs, Suttons, Carters, and many others, would show that the great American hybridist is by no means without a rival in his line of work.

It would hardly be fair to criticise those products of Mr. Burbank's skill and perseverance that have reached us, because it may well be that they are not yet adapted to our climate. At any rate, to name only a few instances, the Burbank plum, the Burbank lily, the Shasta daisy, all so enthusiastically spoken of in the pages of this book and elsewhere, have not, in this country, justified the encomiums passed upon them by the American Press.

When we read of Mr. Burbank's methods of work we do not find anything different from the practices of our "raisers," who are too modest to speak of their efforts as "creations."

Among the "creations" mentioned in this volume is the "thornless edible cactus." Surely we have heard of and seen a spineless Opuntia before attention was called to it in this volume, where it is stated that "nothing more marvellous has ever been done in plant-life"!

Again, "the rare effects developed in the transformation of the columbine" do not differ (so far as we can tell from the illustration facing p. 359) from the stellate columbine known in our gardens for centuries and figured on p. 273 of Parkinson's Paradisus (1629).

A man who has experimented on such a colossal scale for so long a time might be expected to have gathered valuable information on such points as heredity, adaptation, inheritance of acquired characters, as well as formed opinions on Mendelism and mutation. We gather from the book before us that Mr. Burbank's attention has, almost of necessity, been directed to these subjects, and we earnestly hope that now that the Carnegie Institution has granted him a subvention of ten thousand dollars a year for ten years he will find time to record and coordinate his experiments for the benefit of future workers and the increase of biological knowledge.

Incidentally, we glean that Mr. Burbank is not inclined to accept the views of Weismann or of Mendel, but that he looks favourably on the mutation theory of De Vries. Surely no practitioner has had better opportunities of judging of these matters than has Mr. Burbank, and if he will give us his own experiences in his own words, rather than in those of some too partial biographer, the world will be the gainer, and the value of Mr. Burbank's work more accurately gauged than it can be from the perusal of the present volume.

CHEMICAL TECHNOLOGY.

Chemische Technologie. By Dr. Fr. Heusler. Pp. xvi+350. (Leipzig: B. G. Teubner, 1905.) Price 8 marks.

THE author states in the preface that the work is intended for the use of merchants. This at once opens up the question whether a book of this kind, ostensibly written for non-chemists, can fulfil its object. The author is under the impression that a merchant has acquired, in the course of his secondary education, sufficient knowledge to read and interpret chemical equations, and he adopts in his work chemical symbols throughout, in the belief that it would be almost an insult to the German merchant to think him incapable of understanding chemical equations.

The reviewer cannot agree with this opinion in its broad generality. His own experience would lead him to confirm in this respect the truth of the trite old saying, "A little knowledge is a dangerous knowledge." When the commercial director of a chemical works asks his chemist, in times of stress, to use a sulphuric acid of 50° Bé instead of 66° Bé on the score that the former is so much cheaper for the same amount of sulphuric acid, or when the chief clerk struts through the works meddling with the chemistry of the business, then the chemist would certainly prefer the English system of subdividing the work. Of course, there are merchants who are fully able to understand purely chemical questions, but such merchants would certainly have recourse to the extensive manuals on their own specialities rather than study the present work, in which the information on every subject must necessarily be very meagre.

From this point of view the book is not within the horizon of the average chemical merchant. The tendency to explain the subject so far as possible by equations necessarily leads to a twisted and sometimes wrong representation, as these may be read to

mean complete chemical changes, whilst often enough they only express part of the chemical change that is going on. Statistical data, the most useful information to a merchant, are very imperfectly given. Whilst, *e.g.*, the statistics of ammonium sulphate refer to the years 1902 and 1903, other more important branches of chemical technology hark back as far as the 'eighties of last century.

If the question be asked whether this book would prove useful to a chemist, a much more favourable opinion can be pronounced. The work will be found very helpful, as a kind of "Repetitorium," to a chemist who is reading up for examination. Regarded in this light, the book may be said to have been written concisely and to contain an enormous amount of information, put together in a clear and transparent form. Naturally, the attempt of one single author to press the wide range of chemical technology into one small volume carries with it the germ of defect. For in the present state of chemical technology it is clearly impossible for any single person to write on every branch with the necessary authority or even necessary knowledge. The inevitable consequence of such an ambitious endeavour is that books of this kind bear too patently the stamp of writing-desk work. Only in the case of the electrolytical processes dealing with alkali chlorides the author has called in the assistance of an expert. He would have done well to have extended this invitation to other specialists. We therefore find throughout the book many statements which could have been put right by an expert, and we also notice some important omissions. Moreover, some of the weakest chapters, such as those on "leather industry" and "fats and oils," would have been brought into line with the aforementioned chapter on electrolysis. The least satisfactory part of the book are the illustrations. Some of them have done service for half a century, and might have been given their well-earned rest. Others are more in the nature of pictures which convey no information. Others, again, such as the illustration of a native indigo plant, can only provoke a smile.

J. L.

OUR BOOK SHELF.

Future Forest Trees. By A. H. Unwin Pp. 108. (London: T. Fisher Unwin, 1905.) Price 7*s.* 6*d.* net.

WITHIN recent years our forestry literature has been rapidly and steadily on the increase, which may be taken as a sign that more attention is now being given to matters sylvicultural than formerly. The above work is one of the most recent additions, and its thoroughly sound, practical, and scientific character should secure it a wide circulation, not only in this country, but also in America, to which it equally refers.

The title chosen by the author, "Future Forest Trees," refers to those exotic, deciduous, and coniferous species of East, West, and North American trees which might with advantage be introduced into our forests. The work embodies the author's own personal experience, as well as the results gained by more than 100 years of extended experiments which have been carried out in Germany.

The selection of exotic species as future forest trees is not by any means so easy a task as one might at first sight suppose. To justify its introduction and cultivation the new species must have some distinct advantageous characteristics which are not possessed by our indigenous trees, such as greater rapidity in growth, greater resistance to adverse climatic conditions (for example, wind, heat, cold, rain, and snow), greater adaptability to the poorer classes of soil, and such like.

It is to Prof. H. Mayr, of Munich, to whom this book is dedicated, that we are indebted for so much valuable information on this very important question, especially as regards the geographical distribution of forest trees.

The first part of the book deals with the imports of American timber to the German market. Importing timber to Germany, the home of forestry, sounds a little like carting coals to Newcastle; nevertheless, there are at least two sufficient reasons, firstly, because some of these timbers are at present not cultivated in that country, and, secondly, it is a well-known fact that the world's supply of timber is not inexhaustible, and is, in fact, rapidly on the decrease. Hence, while Germany can obtain timber at a reasonable price from abroad, she is conserving her own forest reserves with the full knowledge that at no very remote date the price of timber will have risen to a figure which will amply justify this policy of conservation. Part ii. gives the general results of planting experiments with American trees in Germany, Austria, Great Britain, and Switzerland; and part iii. deals with the sylvicultural characteristics and treatment of the various American species of trees.

We heartily commend this book to all those who are interested in or connected with forestry, as it forms an excellent guide to the cultivation of species which are likely in the course of time fully to justify their introduction.

Elements of Quantitative Analysis. By Dr. G. H. Bailey. Pp. x+246. (London: Macmillan and Co., Ltd., 1905.) Price 4*s.* 6*d.*

AFTER the consideration of some preliminary matters, the author, within the compass of less than two hundred small pages, treats of almost every branch of quantitative chemical analysis, including minerals of many sorts, water, fuel, the products of alkali factories, manures, organic substances, soap, oils and fats, and gases. It follows that the space devoted to each section is very small, and in many cases it would be more correct to say that the methods are indicated rather than described. This economy of words and space sometimes leads to instructions that might cause accidents, as in the description of Kjeldahl's method of estimating nitrogen, where the student is instructed to boil the substance with fuming sulphuric acid, &c., then to "allow to cool and add a tolerable excess, about 50 grams will suffice, of caustic soda. . . . Distill off the ammonia," &c. In other cases the desire to be brief leaves the student without instructions, as in the analysis of water, in which he is told to determine the free and albumenoid ammonia, and referred for the method to a simple description of the estimation of ammonia by Nessler's solution. On the other hand, it is a pleasure to notice that some methods are given that are not generally known, such as the colorimetric estimation of titanium by means of hydrogen peroxide.

The educational value of the work suggested (to which the author refers in his preface) would have been enhanced if the chemistry of the operations and the specific aims of the advisable manipulative pre-

cautions had been given more fully in a few preliminary cases, so that the student might have been helped to understand thoroughly his early exercises. As he gets more advanced he ought to refer to standard works and original treatises. Then this present volume will furnish an excellent series of suggestions as to work that may be done in many directions in order to gain experience and increase his knowledge. C. J.

Elementary Dynamics. By W. M. Baker. Second edition, revised. Pp. x+318. (London: George Bell and Sons, 1905.) Price 4*s.* 6*d.*

THIS text-book follows ordinary lines. The author does well to direct the attention of the beginner at the outset to the fact that *weight* and *mass* are by no means the same thing. Newton's laws are given almost unchanged in words, the second being altered to "rate of change of momentum is proportional to the impressed force, &c." The word *rate* is, in strictness, ambiguous, since it does not necessarily imply time-rate; and the explanation (p. 33) that "rate of change of momentum" means the change of momentum *in* the unit of time is not quite accurate, since the unit of time may be an hour or a week. The poundal figures a great deal; but, happily, as a rule, the values of forces are given in gravitation measure in the answers. The antiquated and inaccurate terms *power* and *weight* are used in the discussion of machines, although *power* has been very properly defined as time-rate of doing work. The old method of defining the instantaneous value of a variable angular velocity as "the number of unit angles which would be described in the unit of time, if during that unit the angular velocity remained the same as at the instant under consideration" is adhered to; but this definition defines nothing. The author is commendably clear in his warning to the student that "centrifugal force" is not a force acting on a revolving body. In the discussion of projectiles, the eye is not pleased by the sight of "$u \sin at - \frac{1}{2}gt^2$" for $ut \sin \alpha - \frac{1}{2}gt^2$; and it is just possible that a beginner may (by the inscrutable ingenuity for error which students sometimes exhibit) misunderstand the expression altogether.

The book contains a very large collection of examples, and has, as a slight departure from the plan of ordinary text-books, a short chapter at the end showing how initial tensions are calculated when cords are cut or broken.

A Historical Geography of the British Colonies. By C. P. Lucas, C.B. Vol. ii. The West Indies. Second edition, revised by C. Atchley. Pp. 348; diagram and maps. (Oxford: The Clarendon Press.) Price 7*s.* 6*d.*

THIS valuable work has been published at an opportune moment, for the decisions of the Imperial Government in such matters as the withdrawal of the white troops and the non-renewal of the mail contract have led to a widespread idea that our West Indian possessions are about reaching the most momentous stage in their long history, namely, their transfer to the United States—an extreme step which is hardly likely to be taken in our time. The volume deals not only with the West Indian islands proper, from Jamaica round to Trinidad, but also with the Bermudas, the Bahamas, the mainland colonies of Guiana and Honduras, and even the far distant possessions in the Cape Horn region—the Falkland Islands and South Georgia. The total area aggregates 127,345 square miles, Guiana alone being 100,000, and Honduras 7562 square miles. The remainder is cut up into a multitude of small islands, ranging down to the Bermudas group, of 19 square miles. Yet each island, however small, has its own separate history. Originally the Spaniards had Papal authority for taking possession of the New World, but they were not a colonising people, and as "conquerors and crusaders they looked for a large area of territory; consequently, while they discovered the whole ring of islands, they settled on the larger ones only, and on those only which lay nearer to the continent. With the smaller islands they had little dealings beyond carrying off their inhabitants for slaves." There was thus no effective occupation of the large majority of the islands, and English, French, and Dutch buccaneers appearing on the scene, in the course of time they divided the islands between them, the lion's share eventually, as the result of treaties or wars, falling to the English. The earliest of the British possessions was Barbados (1605), the latest, by conquest, St. Lucia and Tobago (1803). Obviously, within the compass of a single volume, only a general historical account of each colony could be given, and Mr. Lucas has accomplished his task most successfully. But in addition to the purely historical portion he supplies much information relating to the geography, the geology, and the climate of the islands—as varied as their history. The economic conditions are also fully set forth, the particular industries of the several islands, their exports and imports, and so on, while the form of government of each colony is described. There is a very complete index, and at the end of each chapter there is a list of books and publications which will afford the reader fuller details, many other authorities being referred to in footnotes.

Vorlesungen über mathematische Näherungsmethoden. By Dr. Otto Biermann. Pp. ix+226. (Brunswick: Vieweg und Sohn, 1905.) Price 8 marks.

THE aim of the author of this book is to give a connected and fairly comprehensive account of the most important mathematical methods of approximate calculations. Strictly speaking, all scientific calculations are approximate; but by suitable processes the approximation may be carried to a degree of accuracy sufficient to satisfy the most exacting requirements. How best to effect the approximation in any given case must ever be a most important problem. The necessity for it begins with ordinary arithmetical operations, to which, accordingly, Dr. Biermann devotes a large part of the first chapter. A good deal of detail might have been spared here if only to make room for a complete account of Horner's method of solving numerical equations and extracting roots. The algebraical theory only of Horner's method is given in a later chapter, but not the expeditious arithmetical process. To give an idea of the scope of the book, we find systematic discussions of the calculations of logarithms, graphical solution of equations, methods of interpolation and differences, determination of Fourier coefficients, methods of quadrature and cubature, and a chapter containing, among other things, a description of the sliding scale and Amsler's planimeter. There are some interesting novelties in the sections on graphical solution of equations which might well find a place in our English text-books of algebra, such, for example, as Mehmke's method. The book does not cover all the ground indicated by the term *Näherungsmethoden*, but it certainly covers more ground than any other book. Indeed, it fills what has been until now a distinct blank in mathematical literature; and the author is to be congratulated on the production of a work which cannot fail to be of service to the student of mathematical methods.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Insectivorous Water-plant from Trinidad.

SPECIMENS of the carnivorous water-plant from the Trinidad Pitch Lake, referred to in the note on p. 230, have been received at Kew from Mr. Hart. It is not, however, as supposed, "a species of Nitella," which is an aquatic cryptogam, but a flowering plant, and a species of Utricularia.

The habits of these plants are fully discussed in Mr. Darwin's "Insectivorous Plants."

W. T. THISELTON-DYER.

Kew, January 5.

The Maximum Number of Double Points on a Surface.

IT is obvious that a surface, like a curve, must have a maximum number of double points; and it is also obvious that all of them may be *conic nodes*, but only a limited number of them can be *binodes*; but so far as I have been able to discover, no formula has been obtained for determining the maximum number. In Hudson's book on "Kummer's Surface," a proof is given that a quartic surface can have as many as sixteen conic nodes, but no general theorem is alluded to. I shall therefore state a formula by means of which the maximum number can be calculated.

Let a surface of degree n and class m have C isolated conic nodes. Let $\bar{\iota}$ and ι be the number of double and stationary tangents possessed by any plane section of a tangent cone the vertex of which is an arbitrary point. Then it is not difficult to show that

$$m = n(n-1)^2 - 2C \qquad (1)$$

$$\iota = 4n(n-1)(n-2) - 6C \qquad (2)$$

$$2\bar{\iota} = \{2C - n(n-1)^2 + 5\}^2 - \{n(n-1)(3n-14) + 25\} \qquad (3)$$

Now ι and $\bar{\iota}$ must be zero or positive integers; also m must be a positive integer which does not fall below a certain limit, and these conditions will in general be satisfied by taking

$$2C - n(n-1)^2 + 5 = \pm k,$$

where k is the least odd integer the square of which is not less than $n(n-1)(3n-14)+25$. The sign of k must be determined from the above mentioned conditions, and should the least value of k fail to satisfy them a greater one must be taken.

Sounding Stones.

MANY hard and compact varieties of rock are sonorous when struck. Flint nodules often possess this property. The purity of the tone appears dependent upon the length, calibre, and homogeneity of the nodule, the best results being obtained from the long and slender forms. At Studland Bay I have collected many of these "musical" flints, and obtained one from a chalk pit near Faversham which can be used as a gong when suspended. This particular specimen is nearly 2 feet in length (it was once longer), and is scarcely as thick as a rolling-pin!

Many years ago I saw a "rock harmonicon" in the museum at Keswick. It was formed of strips of rock (known as "clinkstones") arranged on the principle of the dulcimer, upon which various tunes could be played.

The phonolite of the Wolf Rock, nine miles south of the Land's End, possesses sonorous properties, and Sir Wyville Thomson has described St. Michael's Mount, an island near Fernando Noronha, as being entirely formed of phonolite which "literally rings like a bell" on being struck.

In quarrying the rock from the Whit Bed, at Portland, the workmen profess to be able to judge of the quality of the limestone by the clearness of the metallic ring emitted from the blocks on being struck.

January 5. CECIL CARUS-WILSON.

Heat a Mode of Motion.

THROUGHOUT Swedenborg's "Principia," published in 1733, both heat and light are constantly regarded as ethereal undulations. The definitions of heat as a rotary movement of minute ether particles will be found in part iii., chapter v., No. 21; chapter vii., No. 10; chapter viii., Nos. 8, 9, 10, 16.

The following is from the "Principia," part iii., chapter vii.:—

"Whatever the ether presents to our organs by means of colours, the air presents to us by means of modulations and sounds. Thus Nature is always the same, always similar to herself, both in light, and in sound, in the eye and in the ear; the only difference is that in one she is quicker and more subtle, in the other slower and crasser."

Although this is not an example from the seventeenth century, it anticipates the theories of Rumford and Young as to light and heat by some sixty years.

CHARLES E. BENHAM.

Colchester, December 23, 1905.

The Naming of Colours.

PERHAPS some of your readers would be interested in, and could suggest some explanation of, the following rather fanciful colour term. A light purple, almost a mauve, is called by the Chinese 雪 (süt_0) 青 (Ts'eng), 色 (shik,) "snow green colour." I have asked many educated Chinese for some explanation of the name, but the best I can get is the Chinese are very "fanciful" in the use of colour terms. I may say that the term I have translated "green" is sometimes applied by the Chinese to the colour of the sky.

ALFRED H. CROOK.

Queen's College, Hong Kong, December 2, 1905.

Aurora of November 15.

THE aurora of November 15, 1905, was seen at Szczawnica, in Galicia (Karpathian Mountains), by the meteorological observer Mr. Wojakowski at 9h. p.m. M.E.T.

The day of November 15 and the subsequent night were in Galicia cloudy and rainy. Probably the sky was clear for a while at Szczawnica. The altitude of Szczawnica is 484 metres; longitude, 20° 30′ E. of Greenwich; latitude, 49° 26′ N.

Ascent of Sap in Trees.

WITH reference to an article on the above subject which appeared in your issue of October 26, 1905, the following extract from a paper—which your contributor has doubtless not seen, published nearly ten years ago—will probably interest some of your readers.

FRANK HARRIS.

Maryland, Saundersfoot, December 25, 1905.

EXTRACT FROM *Indian Engineering*, FEBRUARY 8, 1896.

Ascent of Sap in Trees.

Among the various theories which have been advanced to explain the circulation of sap in plants, those dependent on purely mechanical principles are, as has been pointed out, entirely untenable. That hypothesis which relies solely on the osmotic action of the root hairs, though adequate in itself to account for the rise of water to almost any extent, is not compatible with the so-called "negative" pressure observed to exist in the vessels of living timber. The last mentioned among the explanations to which allusion has been made—that which invokes the aid of what may be loosely described as the vital principle—though unobjectionable in itself, unnecessarily complicates

the question; and while some of the difficulties which present themselves upon detailed examination may be overcome, others are less easily surmounted. In the trunk of a tree it is only the cambium itself which can properly be regarded as consisting of living cells—if we use the expression in its usual sense. Besides protoplasm the cambium cell contains a nucleus, and splitting up to form the growing wood is evidently and unquestionably a living cell. The sap cannot, however, be considered as entirely rising through the cambium alone; while the medullary rays and wood-parenchyma, although they both contain protoplasm or such like organic substances, are in no other respects like living tissue. They may be regarded simply as store houses containing nutritive matter, or as actively engaged in the plant's circulation, or as acting in both capacities; but scarcely can they be described as centres of vitality.

The theory which most readily commends itself to our ideas of probability is that which regards osmosis as the primary and all potent cause of the sap's ascent in plants; not taking place in the root alone, as was supposed by those who advocated the earlier theory, but active throughout the whole height of every tree. Concerning osmosis itself it is well to remember that the phenomenon contains nothing transcendental or beyond the reach of ordinary molecular physics for its complete explanation. We know that the particles of a liquid, though far from possessing that mobility which in a gas is due to the great extent of free path enjoyed by its molecules, are constantly in a state of translational motion with regard to each other. The phenomenon of diffusion in inorganic solutions obviously suggests the conclusion that this capacity depends largely upon the relative simplicity which characterises the molecule's construction. Especially is this idea forced upon us when considering the relative diffusibility of various solutions. Here we find the rate of diffusion bearing a definite relation to the solution density; the square of the time of equal diffusion being in the case of such solutions equal to their solution density. It would appear, apart from all questions of chemical combination, that each molecule—or perhaps group of molecules—of the solvent becomes attached to a certain number of molecules of the dissolved substance; this complex group holding together so far as diffusion and osmosis are concerned. Under such circumstances it is only to be expected that the rate of diffusion, which means the passage through intermolecular fluid spaces, or of osmosis, which consists in the passage through interstitial spaces in a porous solid, should vary quite as much as is observed to be the case.

It is true the relatively small differences in the rate of passage through porous bodies observable when inorganic solutions are compared with each other, seem to depend principally upon chemical action between the solutions and the substance; but in the much more marked difference observed when we compare the dialysis of crystalloid and colloid bodies, this does not depend on any such action.

Now in a plant we have a system in which the process of nutrition is going on at both ends, the roots and the leaves of a tree; it is, however, the organic colloid substances which are manufactured in the leaves, while in most part inorganic or crystalloid compounds are absorbed by the roots Both forms of nutriment are required at every point of the tree. The colloids have to descend, the crystalloids and water have to be raised. Constant evaporation from the leaves by maintaining "negative" pressure in the vessels greatly facilitates the rise of water from below; but the motive power is osmotic action taking place between any or every pair of cells in the chain. The "air bubbles" which form a *chapelet de Jamin* in the vessels and prevent the fall of any water previously raised by osmosis, at times when demand falls or moist air saturating the leaves supplies all water necessary from above,' very possibly convert the fluid column itself into the equivalent of a porous body suitable for the action of osmosis to make itself felt between each pair of drops as they hang suspended in the vessels. The film of liquid surrounding each bubble is as a narrow space in a porous body through which the simpler and smaller groups of atoms can more readily pass than can that cumbrous collection which constitutes the physical molecule of any colloid solution. This action adapts itself exactly to the plant's requirements. Should any sap fall short at any point of water or crystalloid solution, osmotic action immediately supplies what is required from below; while the enormous pressures which dialysis can bring into play leave gravity *une quantité negligeable*. The details characterising this action as observable in conifers, as distinguished from dicotyledonous trees, will doubtless vary. The former suggest to most unbotanical minds the idea of an earlier and less highly developed type. The tracheides of a conifer act simultaneously as conducting vessels and as hollow cells in the structural framework of the trunk considered as a beam; while these purposes are more or less differentiated in the case of dicotyledonous plants. In this latter case the wood-parenchyma cells surrounding the "vessels"—filled as they are with colloid matter—appear to supplement the action of the medullary rays, not here in such close connection with conducting tracheides as they are in the case of conifers. The presence of all this colloid matter, scattered throughout the conducting mass and closely connected with the tracheides or with the fitted vessels, probably act as a reservoir and enlarge the sphere of the osmotic action, thus avoiding violent changes and preventing any very noticeable difference in sap density occurring throughout the tree's height. A gradient, however, marking difference in proportion between colloids and crystalloids must necessarily exist whenever water is rising, and this would naturally be expected to follow the introduction of these different forms of nutritive matter at opposite ends of a chain.

ELEMENTARY GEOLOGY.[1]

IF a new elementary text-book of geology is really in request, no better author could be found than the president of the Geological Society of London for 1905. We venture to prefer this work to his somewhat similar "Agricultural Geology," and hope that candidates for a diploma in agriculture will now make use of both. The author, while engaged upon his task, appears to be absolutely devoid of the emotion which "nature-study" provokes in other men in various measure, and his introduction, if a little cold, should lead to accurate observation and understanding. The photographic illustrations are refreshingly large, and include successfully the forms of familiar fossils and even of flint implements. Four pins fixed in a dull white wall would, however, have served as a more satisfactory support for a helpless belemnite than the operating table and other apparatus displayed in Fig. 29. The striking relic of a Triassic land-surface, photographed by Prof. H. E. Armstrong (Fig. 27), is here reproduced, as an example of the admirable landscapes in this volume.

Our only question about the book is as to the class for whom it is intended. In the frequent absence of systematic scientific training in English schools—things are fortunately different now in Ireland scholars may come up to our universities completely ignorant of chemistry and physics. They may also be ignorant of the animal and vegetable forms around them, and they are certain to believe that coral is a substance laboriously manufactured by an insect. We take it that, on contact with Dr. Marr and the well-known Woodwardian collections, such scholars may become attracted towards geology. Hence, in the present work, this complex subject, relying for its evidence on almost every other science, is treated as one to be laid before babes, who have never handled a blowpipe, or stroked the back of a cat to see that it possessed a spinal column. From these pages the reader may "proceed to the perusal of more advanced treatises." But what

[1] "An Introduction to Geology." By J. E. Marr, Sc.D., F.R.S. Pp. viii+230. (Cambridge: University Press, 1905.) Price 3s. net.

is to be his course of study in between? Before the advanced treatise, or, at any rate, such a one as Dr. Marr would approve, can be really entered on and appreciated, the student must surely have some practical acquaintance with carbon dioxide and silica as chemical substances, with "boneless animals" and "those possessing bones," and with other matters that are here mentioned as if they were absolutely new to his intelligence. On pp. 224 and 225 the beginner is sent out into the open country as his "true museum." This is excellent advice for the true beginner in geology, but not for those beginners in science whom Dr. Marr, from his experience of English public schools, finds himself compelled to contemplate.

Among the excellent points in the present treatise we notice the early introduction of conceptions of crust-movement, which render descriptions of other phenomena far more easy of comprehension; the reference to what is often known as "plucking" in the action of glaciers (p. 57); and the concise account of plains of denudation (peneplains) on p. 99. Among the very few slips, we may note that Kimeridge (p. 179) is in Dorset, not in Wiltshire; that the insoluble part of felspar (p. 79) does not by itself form china-clay; and that the phrase "evaporation of water by the sun" (p. 67) is scarcely a happy one. The fan-structure on p. 93 is, we think, not that usually thought of in connection with the term.

On p. 65 we must invoke subsidence of the crust to enable the sea to perform all the work there claimed for it; and we should like more sympathy on p. 89 with the view that the earth is continually losing moisture from its interior. Lastly, the author (p. 181) should not, even by an accident of phraseology, encourage a belief in the existence of "fossil thunderbolts." But these small asperities only give an edge to our appreciation. GRENVILLE A. J. COLE.

TIDAL RESEARCHES.[1]

ONE of the crowning features of the enunciation by Newton of the law of universal gravitation consisted in the fact that herein the phenomena of the tides and their relationship with the moon could for the first time be coordinated with other well-known phenomena of the solar system. Though the principal phenomena of rise and fall and ebb and flood of the sea must have been recognised by coast dwellers and navigators from the earliest times, the theory of the tides as it exists to-day may fairly be said to have originated with Newton, and its purpose has largely been to examine to what extent these phenomena are attributable solely to a gravitational cause or how far it may be necessary to invoke some other exciting or controlling influence.

It was early recognised that a theory which failed to take due account of the inertia of the water, of the earth's rotation, and of the curvature of its surface could but inadequately represent the phenomena actually existent in nature, and the reduction of the tidal problem to a mathematical form in which all these features were duly taken into account was first accomplished by Laplace; since his time the equations furnished by him have formed the basis of almost all attempts to further the study of the tides from its purely theoretical aspect. The theory of tides in narrow canals developed *in extenso* by Airy, though not directly based on Laplace's equations, consists largely in the discussion of a special type of solvable cases of the more general mathematical problem propounded by Laplace. In the memoirs under review the author emphasises the hopelessness of such attempts to realise their main purpose of providing a theory sufficiently exact and yet sufficiently general in character to allow of direct comparison with observations, as is the practice in the study of other gravitational phenomena such as the planetary motions, and proposes a new method of attacking the problem. An essential difference between this method and that of Laplace consists in the fact that in the former the influence of the earth's rotation is regarded as of secondary importance. Such solutions of Laplace's equations as have been obtained, which allow of an exact estimate of the

[1] "A Manual of Tides." Part iv. A, Outlines of Tidal Theory. Part iv. B, Cotidal Lines of the World. By Rollin A. Harris. Appendices to Reports of U.S. Coast and Geodetic Survey.

influence of the rotation in the restricted problems dealt with, by no means appear to justify this course.

If, however, a complete tidal theory which should adequately account for all the phenomena of observation has hitherto been found wanting, at least considerable advance in the coordination of observed phenomena has been obtained by the introduction of the harmonic analysis for the discussion of tidal observations, while tidal records suitable for such analysis have accumulated. These, so far as they are accessible at all, are scattered through various scientific publications, and the author has rendered a valuable service to all interested in tidal phenomena in collecting them in tabular form in a single memoir. The tables given on pp. 664–677, part iv. A, and pp. 342–351, part iv. B, contain the results of the harmonic analysis of tidal observations taken at more than four hundred stations distributed throughout the world, and probably contain almost all information of a precise character in relation to the tides at present available. These tables give the amplitudes and phases of the principal types of oscillation as derived from observation alone, and only involve theory in so far as it enables us to assign the periods in advance by means of exact astronomical data. It is to be regretted that in no case is any indication given of the degree of precision with which the analysed results reproduce the actual observations from which they are derived, or of the extent to which they confirm the theory on which they depend.

A considerable portion of the memoirs is further devoted to an attempt to coordinate the results derived from different stations so as to form a comprehensive picture of the general progress of the tide-wave over the surface of the ocean, and the results are exhibited in a series of charts indicating the position of the wave crest at each successive cotidal hour.

The construction of these charts is, unfortunately, but vaguely indicated. As already stated, no ready means is provided of estimating the value of the material used for the purpose, or of the methods used for its combination.

In so far as these charts are based on the results of observation alone we are prepared to believe that they give a fairly accurate representation of the actual tides in the regions where observations are sufficiently numerous to supply the necessary information, but, as is well indicated in the cotidal chart due to Berghaus and reproduced by the author, there will remain very considerable tracts of the ocean surface about which no observational information is available, and which are left blank on the charts prepared by Berghaus. In fact, as tidal observation is almost of necessity confined to the neighbourhood of the coast lines, the only method of filling in such blanks is to have recourse to theory, and the correctness or otherwise of the charts prepared by the author must therefore depend to a very considerable extent on the correctness of the theory which he has put forward, which forms the principal subject of Part iv. A.

This theory has already been the subject of adverse criticism in NATURE (September 4, 1902, p. 444), and we cannot but regret that we have to adhere to the objections to it previously raised.

Without reverting to these objections it is rather our purpose here to examine the particular applications of it now dealt with in part iv. B, which constitute the chief purpose for which it was designed. The object of the author, as he himself expresses it, is "to obtain through theoretical considerations . . . a first approximation to the times of the principal ocean tides," *i.e.* the phases of the oscillations in relation to those of the disturbing forces which produce them. The times in question are deduced from a theorem based on the analogue of the compound pendulum which asserts that in maintained simple harmonic motion under the action of friction "the virtual work of the external periodic forces is zero at the instant of elongation." If we rightly understand the significance of this theorem, it would appear to imply that, at the instant of elongation, the disturbing forces which give rise to the type of motion under consideration form an equilibrium system. We conclude either that they are in equilibrium throughout the motion or that they are in equilibrium at this instant in virtue of the fact that their resultant, which is *ex hypothesi* of a simple harmonic character, is passing through its zero phase. The former hypothesis may be dismissed as giving rise to no permanent oscillation; the latter indicates a phase difference of a quarter of a period between the phase of the oscillation and that of the resultant disturbing force.

The application of the theorem in question to the tidal problem is somewhat obscure, but the illustration of the simple pendulum presented by the author enables us at once to recognise an essential condition under which it is applicable. The phase difference in this case is correctly expressed by equation (297), which indicates in general a phase difference of zero or half a period when friction is slight. When, however, friction is sufficiently great the phase difference may amount approximately to a quarter of a period, and the same will be true even with small friction when there is an exact coincidence between the period of the disturbing force and the "natural" period of vibration of the pendulum.

Thus the fundamental theorem on which the determination of the phase depends only holds good if we regard friction as sufficiently large to control the phase, and unless the relative influence of friction in comparison with other causes which influence the phase is in some way known, the phase will remain quite indeterminate. Of course it may be contended that in the case of the tides the conditions necessary to render friction the controlling factor exist, but this contention is nowhere put forward explicitly by the author, and we are of opinion that it could not be substantiated. We are further of opinion that the effects of friction on phase will be everywhere comparatively insignificant, so that we should expect to find the phases of the oscillations, so far as they can be resolved into separate simple harmonic types, approximately in agreement with (or differing by half a period from) those of the disturbing causes instead of, as the author's theory requires, differing from them by a quarter of a period. We conclude that the author's theory ceases to be available even to lead to a "first approximation" in the determination of the phases.

We can thus only regard the charts produced, except in so far as they are controlled by direct observations, as a speculation on the part of the author unsupported by scientific evidence, and regret that an otherwise painstaking and far-reaching research on our existing knowledge of the tides has been marred by the intervention of an unsatisfactory theory which we feel bound to regard as not merely inadequate, but for the purposes to which it is applied actually misleading.

S. S. H.

AGRICULTURAL EDUCATION AND COLONIAL DEVELOPMENT.

IN a paper on "The Teaching of Agriculture" read by Mr. F. B. Smith, director of agriculture in the Transvaal, before the British Association, there occurs a statement which is of special interest to educationists and to the public of this country. The paper was read with the object of directing attention to the keen desire for agricultural education that now exists in South Africa, and to the improvements in the condition of the colonies which might be looked for if a satisfactory system of education and research were established. But though colonial Governments are willing, and the enlightened members of the agricultural community are anxious to get on, progress is slow, and chiefly because suitable teachers for agricultural colleges and other officers for colonial departments of agriculture are hard to find. The words used by Mr. Smith are:—"The difficulty of obtaining men qualified to fill such positions is great, and frequently one of two things happens: either an *unsuitable man from the Homeland* (the italics are ours) is appointed, with the result that a department is seriously hampered or discredited, or a selection has to be made from abroad. I am not speaking without experience, for I could give many examples in support of my argument that a great deal of harm has been caused to agricultural administration and education in the colonies by the sending out of inexperienced and unsuitable men from Great Britain." Again, after stating that the demand will continue, and is likely to increase, Mr. Smith asks, "Cannot some steps be taken to improve matters, and to supply the want?"

Unfortunately it is not only in South Africa that the Mother Country's insufficiency is being felt, for within the past few years there has been quite an extraordinary awakening to the value of agricultural education in the British possessions, and the Homeland has not been able to afford the guidance and assistance which her colonies expect. That there is an awakening we have ample evidence; thus a recent number of the *West India Bulletin* informs us that the president of the West Indian Agricultural Conference of 1905 remarked:—"Agricultural education is at the root of the successful development of these colonies," and another speaker referred with surprise to the rapid rise in importance of this subject. Again, from the Indian Financial Statement for 1905 we learn that the Government of India, which in 1902–3 spent about 60,000*l*. on improving agriculture, has now sanctioned an expenditure of 250,000*l*. for the provision of agricultural institutions, experimental farms, &c. But although this forward policy has the approval of all sections of the Indian public, it must wait, for in India, as in South Africa, the problem is to find men competent to give effect to the policy.

The director of agriculture for the Transvaal is perhaps too severe on the "unsuitable man from the Homeland." The good work accomplished by this same "unsuitable man" in the past ten years has been one of the chief causes of the rise in popularity of agricultural education. But it must be admitted not only that men are hard to find, but that when found they seldom have the training which is desirable. The fact is that Britain still looks upon agricultural education purely from the national standpoint, and gives no thought to her colonies. Through the Board of Agriculture, agricultural institutions in England and Wales receive about 10,000*l*. per annum; but these grants are made to provide for the education of the English farmer, and without reference to our foreign possessions.

A few weeks ago a deputation waited upon the Board of Agriculture to ask that increased grants might be given for teaching and research in connection with English agriculture, and it was admitted by the Board that further aid in this direction was desirable. If the present grants are insufficient for the special needs of this country, it is clear that they are quite inadequate for the requirements of Greater Britain. It may be argued that India and the colonies should provide for themselves; but we hope that Mr. Smith's question may not receive this answer. Greater Britain makes the reasonable request, "If you send us men, send us trained men," and if we neglect this request our colonies must find men elsewhere. They cannot mark time indefinitely, nor can they risk their prosperity by engaging the services of incompetent men.

England is herself content with her small outlay on agricultural education and research, but we must not conclude that what is good enough for the Mother Country is good enough for her colonies. English agriculture is highly developed, is conservative in its methods, and there is no agricultural party to be reckoned with by the English statesman. We do not ask for, and we do not get, the assistance claimed by the farmers of countries like Denmark and the United States. In India and the colonies it is different; agriculture is undeveloped, applied science may do much for the farmer, and the prosperity and contentment of the agriculturist are of great political importance. Though, therefore, the English agriculturist does not complain of the meagre endowments of agricultural science, we must not assume that those responsible for the development of Greater Britain will remain satisfied with what this country is now doing. The colonies have hitherto taken our men, because men trained in British schools and universities have been their traditional leaders; but it is clear that if we wish them to continue to do so we must make greater efforts to meet the new demand.

Nothing could possibly be more damaging to the reputation, not only of English teachers of agriculture, but of England, than such an experience as the director of agriculture for the Transvaal recorded before the British Association. If our men are incompetent, if they are unfit to lead, the sooner, not only our teachers, but our statesmen, take the matter up the better. The colonies must know, and without delay, that the universities and colleges of this country can supply trained agriculturists. We are indebted to the director of agriculture for his plain if unpalatable warning. There appears to be a danger that while the means of securing a preference for our merchandise are being discussed, we may lose the preference now accorded to our men.

MAGNETIC WORK IN INDIA.[1]

THIS relates to the temperature coefficients of horizontal force magnetographs of the Watson pattern belonging to the Indian Survey. The magnet system consists of magnetised iron wires, fixed parallel to one another, in a framework which is attached to a quartz fibre. The upper end of the fibre is attached to a torsion head, by turning which the magnet system is brought nearly perpendicular to the magnetic meridian. With increase of H (horizontal force) the magnet turns until the increased torsion balances the increased magnetic couple, and the position of the magnet is recorded

[1] Survey of India. Professional Papers, 1905. Serial No. 8. Experiments made to determine the Temperature Coefficients of Watson's Magnetographs. By Captain H. A. Denholm Fraser, R.E. Pp 45; with 6 plates and 5 sheets of curves. (Calcutta: Office of the Superintendent of Government Printing, India, 1905.)

photographically by means of a beam of light reflected from a mirror attached to the magnet. With rise of temperature the magnetic moment diminishes slightly, whilst the rigidity of the quartz increases, both causes tending to diminish the angle of torsion and so simulating a fall in H. Measurements made on one of the magnetographs prior to its despatch from England showed a temperature coefficient of approximately 6γ for 1° C. ($1\gamma \equiv 1 \times 10^{-5}$ C.G.S.); but the values obtained in India with different magnet systems and suspensions are mostly about 12.5γ for 1° C. There is, however (see footnote p. 13), no necessary contradiction between these results. The untwisting caused by a given rise of temperature varies as the total angle of torsion, and this varies as the local value of H. But H in India is nearly twice as large as in England. Thus the movement of the magnet due to the change of rigidity in the fibre caused by a rise of 1° is nearly twice as big in India as in England. The memoir discusses the temperature experiments made in India, and the difficulties arising from imperfect temperature control, defects in quartz fibres or in the method of fixing them, and from other causes. The observational data are recorded, and exhibited in the curves, with a detail which is unusual in a printed volume. The values found for the temperature coefficients *in India* are five times larger than those applicable *in England* to some magnetographs of older types with metal suspensions. Even in magnetic chambers under refined temperature control, a small temperature coefficient has advantages which can be fully appreciated only by those experienced in the reduction of magnetic data. Thus the results of the present memoir, though of limited general interest, deserve the attention of instrument makers.

NOTES.

WE regret to see the announcement that Prof. C. J. Joly, F.R.S., Royal Astronomer of Ireland, died on January 4 after a long illness. He was only forty-one years of age.

A BILL which provides for the adoption of the weights and measures of the metric system in all departments of the Government of the United States on July 1, 1908, has been introduced into Congress.

A CENTRAL NEWS message from New York states that by the will of the late Mr. Yerkes the Yerkes Observatory, Chicago, is given the sum of 20,000*l*.

ARRANGEMENTS are being made for the celebration of the twenty-first anniversary of the foundation of the Royal Geographical Society of Australia, Queensland. It is proposed at the end of the current session, in the last week of June, to carry out some appropriate form of commemorative ceremonial to mark the close of the first twenty-one years of activity of the society.

ON Tuesday next, January 16, Prof. E. H. Parker will deliver the first of a course of three lectures at the Royal Institution on impressions of travel in China and the Far East. The Friday evening discourse on January 19 will be delivered by Prof. J. J. Thomson, the subject being some applications of the theory of electric discharge to spectroscopy. On February 2 the discourse will be delivered by Prof. S. P. Thompson on the electric production of nitrates from the atmosphere.

As the signature "H. Weir" occurs so frequently to the illustrations of "Wood's Natural History," which was the popular zoological work of a generation ago, a reference to the death of Mr. Harrison Weir, the well known animal artist, claims a place in our columns. Mr. Weir, who was born at Lewes in 1824, died at his residence at Appledore, Kent, on January 3, at the close of a long period of retirement. Although his portraits of wild animals can scarcely be compared with those of Wolf, they are in most cases—except when drawn from menagerie specimens in poor condition—true to nature and display considerable spirit. Mr. Weir's special *forte* was, however, the portraiture of domesticated poultry, and his work "Our Poultry" has a permanent value as an authentic record of the characteristics of the different breeds at the time it was written. As a judge of poultry and pigeons the deceased artist had a high reputation.

THE first expedition sent out to West Africa by the Liverpool Institute of Commercial Research in the Tropics left England on January 6. The members, who are conducted by Lord Mountmorres, director of the institute, are:—Mr. Kenneth Fisher, chemist; Mr. L. Farmer, botanist; Dr. Slater Jackson, entomologist; and Mr. Coates, commercial adviser. The expedition is proceeding to Dakar, Bathurst, Konakri, and, if possible, to the Cameroons. Being only an experimental expedition, the stay on the west coast will not be of very long duration; in fact, Lord Mountmorres is to return in time to visit the exhibition of rubber at Ceylon in April. But should the results prove satisfactory there is every probability that the institute will dispatch a second expedition to spend a long period in Africa. One of the chief objects of the expedition will be an inquiry into the cultivation of rubber—how to improve the quality of West African rubber in order to bring it up to the same standard as the similar rubber from other colonies, and how to protect and increase the present supply. An effort will also be made to discover new sources of oils, and to find means of increasing the supply by making use of present waste. As regards the study of the prospects of West Africa becoming a fibre-producing country, this branch of the work will include investigation regarding the establishment of hemp, cotton, jute, and ramie growing, and also of new fibres.

WE have received a copy of the report of the Albany Museum for 1904, in which substantial progress is recorded on all sides. It is satisfactory to learn that the proposed cooperation between the museum and the Rhodes University College promises to be of advantage to both institutions. Dr. Schönland, the director of the museum, has already been appointed professor of botany in the college.

MUCH interest attaches to a paper by Mr. Pilgrim in part iii. of the *Records of the Geological Survey of India* for 1905, in which the author describes an elephant skull from the alluvium of the Godaveri valley. This skull belongs to *Elephas namadicus*, of Falconer and Cautley, but the author brings forward evidence which in his opinion proves the identity of that form with the European *E. antiquus*.

OUR knowledge of the land and fresh-water molluscs of Formosa and Japan has been greatly extended by the work of Japanese collectors, the results of which are described by Messrs. Pilsbry and Hirase in the October, 1905, issue of the *Proceedings of the Philadelphia Academy of Sciences*. The collections from Formosa were made in Taiwan, and chiefly consist of land-shells; but although no labour or expense were spared, the number of specimens procured was not so large as anticipated. Nevertheless, out of a total of seventy-one species, twenty-

seven, together with thirteen new subspecies, are described as new. The Japanese collection was chiefly made in the Kyushu and Ryuku chains of islands, and is most satisfactory, as we have now a fair knowledge of the snails of all the larger and of many of the smaller islands.

THE muscles of the jaws and pharynx in dog-fishes and skates form the subject of an illustrated article by Mr. G. E. Marion in the December, 1905, number of the *American Naturalist*. Considering the marked difference in the shape of the two species, the similarity in their muscular system is noteworthy; but, as might have been expected, the skate possesses a few muscles not found in the dog-fish. The deep muscles of the trunk of the former are described for the first time. In another paper Dr. E. N. Transeau discusses the forest-centres of eastern North America, and arrives at the conclusion that there are four such developmental areas, namely, the great conifer forest of the north-east, the deciduous forest of the Ohio basin, the south-eastern coniferous tract, and the insular tropical forest of southern Florida, the centre of which is in the West Indies. The forest-centres correspond with centres of high temperature and humidity.

SOME practical results may perhaps follow a paper contributed by Mr. E. Iwanoff to *Biologisches Centralblatt* of December 15, 1905, on the cause of sterility in zebra-pony hybrids. Sterility appears to attach to the male and not to the female hybrids, although the latter really produce this sterility. For it appears, according to the author's researches, that the spermatozoa are destroyed by leucocytes while within the body-cavity of the female. The female-blood is, in fact, found to contain a substance known as spermatoxin, which acts fatally on the spermatozoa. A similar substance also exists in the blood of female hybrid trout, but as impregnation of the ova takes place outside the body-cavity, no ill results follow to the spermatozoa. It is suggested that in the case of female zebra-hybrids the effects of the spermatoxin should be neutralised by the injection of an anti-spermatoxin serum.

IN the *Biologisches Centralblatt* (December 15, 1905) Prof. Gorjanović-Kramberger discusses the relationships of the race of men whose remains have recently been discovered at Krapina, south of the Styrian frontier. From the examination of these remains it appears that the Krapina race is identical with the one from Neanderthal, Spy, La Naulette, Schipka, &c., for which the name *Homo primigenius* has been proposed. From this primitive type there seems to be a complete transition in cranial characters, through the upper diluvial *H. sapiens fossilis*, to modern man, who occasionally exhibits some of the peculiarities of the ancestral form, such as the absence of the chin prominence and the presence of wrinkles in the enamel of the molars. The pre-diluvial race of Galley (? Gallows) Hill, England, presents a difficulty, since, although this is the oldest, it is at the same time the most modern type. This is explained by the theory of the existence at this early date of two distinct types of mankind, namely, *Homo sapiens fossilis* at Galley (?) Hill, which had attained a relatively high development, and *H. primigenius* at Krapina, Neanderthal, &c., the advance of which may have been prevented by unfavourable conditions of existence.

THE contents of No. 195 of the *Quarterly Journal of Microscopical Science* relate to the anatomy, histology, development, &c., of various groups of invertebrates, and are all of a highly technical nature. Prof. Haswell contributes the first part of a series of papers on the turbellarian worms, dealing in this instance with Heterochærus, while Prof. Carpenter discusses the segmentation and phylogeny of arthropods, and Mr. Hill records his observations on the maturation of the ovum of Alcyonium. Mr. F. C. Sinclair, in the fourth article, alludes to certain points in the anatomy of the myriopods of the family Platydesmidæ; and in the fifth and last Prof. Minchin describes a new sporozoon infesting the mucous membrane of the human nasal septum. At the end of his paper Prof. Carpenter observes that "the more probable conclusion seems to be not that arthropods and polychæte annelids stand to each other in the relation of descendants to ancestors, but that the two groups represent specialised collateral branches from a common stock. My own view is that their common ancestors were microscopic animals, unsegmented, or with comparatively few segments between a broad head-lobe and a narrow tail-somite. The occurrence of the nauplius larva in some members of all the great crustacean groups justifies the phylogenetic importance attached to that form by Müller."

THE position and relations of the abdominal and thoracic viscera of an adult male negro are described and very fully illustrated in a monograph entitled "Topography of the Thorax and Abdomen," by Prof. Potter, just published by the University of Missouri (University of Missouri Studies, Science Series, vol. i., No. 1). The monograph represents a contribution to "descriptive anatomy"—the raw material out of which, when enough has been accumulated, we may hope to build a "scientific anatomy." For several reasons this contribution, though small, is valuable, first, because of the accuracy of the workmanship; secondly, because it deals with a well developed adult man, accidentally suffocated; and thirdly, because it deals with the Negro race, the anatomy of which at the present moment is of the greatest interest. This interest centres round, not what may be called the normal anatomy of that race, but its variations and abnormalities, and to obtain a knowledge of these, records of hundreds of subjects are required. In the subject described by Prof. Potter the cæcum occupies an abnormally high position, a position recalling that seen in the young European child and in the Anthropoid; this, apparently, is a characteristic of the Negro race, for in four subjects recently dissected by the writer of this note a similar condition was observed. Prof. Potter built up the reconstructions and projections shown in the plates of his monograph from a series of twenty-five sections, into which the trunk was divided after being hardened by the injection of a 50 per cent. solution of formaldehyde—a solution employed first by Prof. Jackson. Prof. Potter is to be congratulated on the manner in which he has carried out a laborious task.

SOME figures quoted by the Governor of the Bahamas in his report on the Blue-book of the Bahamas, according to a writer in the *Journal of the Society of Arts*, give an idea of the extent of the sponge fishery business carried on in those waters. There are schooners and sloops with an aggregate tonnage of 5952 engaged in this industry. Attached to the vessels are 2517 open boats, and 5517 men and boys are employed on them. There are also 291 open boats engaged, manned by the owners living on the coasts of several of the out-islands to the number of 445. Disquieting reports as to the exhaustion of the sponge beds and the increasing quantities of small sponges brought to market, which should have been left in the beds to grow to a proper marketable size, recently led to the enactment of a law under which a sponge fisheries board is established with certain powers for the regulation

of the fisheries, and provided with a small annual grant for expenses. Recently the Bight of Abaco was examined, and the result fully confirms the suspicions previously entertained. It is reported that the beds are thickly sown with small sponges which are constantly being gathered by the itinerant fishermen who are continually working over these fields pulling all the sponge they can find without regard to size or quality, in consequence of which there are very few large sponges to be found anywhere. The spongers living in the settlements all round the coast are in sympathy with the movement for protecting the industry against the wasteful methods complained of, and will welcome any reasonable laws for the protection of the young sponge.

THE manurial experiments with cotton in the Leeward Islands detailed by Dr. F. Watts in the *West Indian Bulletin*, vol. vi., No. 3, may be expected to furnish useful information after a trial of some years, when a succession of crops will have emphasised the necessary requirements, and irregularities of climate can be eliminated by averaging results. Dr. Watts recommends the return of the seed to the land, preferably after crushing to express the oil, or as the manure from animals fed on the seed. From the notes by Sir Daniel Morris on grape fruits and shaddocks it is gathered that the larger fruits, referred to *Citrus decumana*, are generally known as pumelows or shaddocks; the smaller fruits assigned to the variety or species *paradisi* may be distinguished as forbidden fruit when round, or as grape fruit having a pyriform shape.

IN *Science*, June 23, 1905, Prof. B. M. Duggar reviews the present-day problems of plant physiology. On the subject of turgor regulation, allusion is made to the investigations of Mayerburg, which tend to show that increased turgor in fungi is caused by the production of osmotic substances within the cell. The writer refers to Moore's work on the organisms found in leguminous tubercles showing that they can assimilate free nitrogen apart from the leguminous plant, to Laurent's experiments on the effects of feeding diœcious plants with different fertilisers, with the results that nitrogen or calcium appeared to increase the number of staminate flowers, and potassium or phosphorus the number of pistillate flowers, and to Blakeslee's identification of homothallic and heterothallic forms of the Mucorineæ.

THE avenues and fruit gardens of Quetta afford a striking testimony to the beneficent results of the British occupation. Writing in the *Indian Forester* (October, 1905), Mr. E. P. Stebbing traces their origin to the foresight of the early administrators, notably General Sir Stanley Edwardes, Sir Hugh Barnes, and Colonel Gaisford. Cuttings of chinar, *Platanus orientalis*, poplars, and willows were brought from Kandahar in 1882. The avenues consist of a mixture of two or more species from the white and black poplars, the reamer, *Populus sp.*, and Euphrates poplars, the Kandahar, *Salix alba*, Kabul, *Salix acmophylla*, and weeping willows, the plane, and a species of American ash. In the gardens some fine old mulberries point to the existence of these trees previous to the occupation by the British; a few specimens of *Populus Euphratica* are found, and walnuts have been planted with satisfactory results.

WE have received a copy of a paper by Dr. Hans Reusch, of Christiania, on the geographical relations of Norway and Sweden. Dr. Reusch deals with the origin and geographical nature of the present frontier between the two countries, and with the density and distribution of population. The paper is reprinted from the *Geographische Zeitschrift*.

PROF. DR. A. OPPEL contributes to the *Deutsche geographische Blatter* a long paper on the forest regions of the middle and upper Mississippi, the prairie lands of Canada, and the New Ontario. The paper is a continuation of Prof. Oppel's previous studies in North America, and is an account of a lengthened journey undertaken during 1904; it contains an immense amount of valuable and interesting information.

THE *Mitteilungen* of the Vienna Geographical Society contain an interesting preliminary report on observations of the altitude of the forest-line in the Austrian Alps, by Prof. R. Marek. The most important general result is that the forest-line sinks continuously from west to east, the rate of fall increasing towards the east, and a difference of 556 metres being recorded within the area investigated—extending through about five degrees of longitude. The average height of the forest-line is about 750 metres below that of the snow-line.

THE third number of the *Abhandlungen* of the Vienna Geographical Society is devoted to a suggestive paper by Dr. Fritz von Kerner. The author discusses the annual march of temperature in the north temperate zone by considering the ratio between the difference between mean monthly values for April and October and the difference between the mean of the hottest and coldest months of the year. Plotting the values of this ratio on a chart, he gets lines to which the name "Thermoisodromes" is given. The distributions revealed in this way, and by further developments of the method, give results of considerable interest in tracing the relations of the "oceanic" and "continental" elements in the climate of the regions covered.

IN a neat art-green canvas cover, Messrs. Burroughs, Wellcome and Co. have issued their well known photographic exposure record and diary for 1906, and the moderate price of 1s. renders it within reach of every photographer. The important features of this pocket-book have been maintained, and the information brought up to date; the light tables, as was the case last year, are printed on perforated leaves, so that each month may be torn out, disclosing the table for the current month opposite the mechanical calculator fixed to the inside of the back cover. The excellent get-up, finish, useful contents, and general handiness of this exposure record and diary have made it a necessary part of a photographic outfit, and this year the photographer who possesses a copy can compete for prizes offered for pictures produced with "tabloid" photographic chemicals.

WITH the December (1905) issue the *Journal of the Franklin Institute* of Philadelphia concludes its 160th volume, and the varied contents show that the high standard that has characterised this journal for eighty years is well maintained. The more important papers in this number are of metallurgical interest. Prof. A. E. Outerbridge gives an able summary of recent scientific progress in metallurgy. Mr. E. Stütz gives a detailed account of the progress made within the past eighteen months in the introduction in the United States of the alumino-thermic process as applied in engineering practice. The progress has been rapid, and the process has proved quite as successful in America as elsewhere for welding and for the repair of castings. Lastly, Mr. Laurance

Addicks discusses the subject of the electrolytic refining of copper, especially from the point of view of the multiple system. The main differences between this system and the series system are in power cost, compactness, and cost of preparing anodes. The fact that large refineries on both systems are being satisfactorily worked bears witness to the close balancing of the advantages and disadvantages in each case, although much more material is refined by the multiple than by the series process.

DURING the night of January 5–6 the central and southern parts of England experienced a very severe gale; the 6h. p.m. observations received at the Meteorological Office on January 5 gave but little indication of the approach of such a severe disturbance, but were sufficient to justify the hoisting of storm signals on all our west coasts. The weather chart for 8h. a.m. on Saturday, January 6, showed that the centre of the storm, which had travelled very rapidly, lay over Lincolnshire, and that strong gales were prevailing in the English Channel and over the southern and eastern counties. In the London district the gusts were very heavy, but it did not experience the full fury which was met with on the coast, although some injury was caused by falling slates and chimneys, and some trees were uprooted. Several wrecks have been reported from the English Channel, and much damage was done to shipping in the Bristol Channel and elsewhere. On Tuesday afternoon (January 9) London and other parts were visited by sharp thunderstorms, accompanied by heavy rain and hail.

A SIXTH edition of the "Hints to Meteorological Observers," prepared under the direction of the council of the Royal Meteorological Society by Mr. W. Marriott, has just been published. The work has been revised and enlarged, and although only consisting of sixty-seven pages, including text, tables, and many illustrations, contains all that is necessary for ordinary normal climatological stations; its conciseness renders it, in our opinion, all the more valuable, and at the present time—the excellent instructions prepared by Mr. Scott for the Meteorological Office being out of print—it is the most useful book of instructions now available for English observers. Among the additions may be mentioned references to the Richard recording instruments (a want to which we recently referred), fuller instructions in connection with phenological observations, and tables for the conversion of anemometrical values from English to French measures, and *vice versâ*. The work would be a desirable acquisition for all meteorological observers, especially those not conversant with the more comprehensive instructions lately published in the French and German languages.

THE Meteorological Committee has issued a useful little pamphlet (12 octavo pages, with charts) on the relation between pressure, temperature, and air circulation over the South Atlantic Ocean. The introductory remarks state that the preparation of monthly wind and other charts occupied the marine department of the Meteorological Office from 1898 to 1904, and were based on no less than 946,000 observations. The charts were published by the hydrographic department of the Admiralty, and at the request of the Meteorological Council Captain Hepworth, the marine superintendent, undertook the preparation of notes which, with a number of small diagrams, are deductions from an examination of the elaborate charts above referred to. They show the variations, the position and intensity of the areas of high pressure, and their relation to the equatorial doldrums, the distribution of gales, fog, &c. The gales appear to reach the South Atlantic in two ways:—(1) they cross South America between 25° S. and Cape Horn, or (2) they avoid the land, and round Cape Horn to the eastward, following the general drift of air and sea surface. Fog is rarely met with north of the thirtieth parallel, except near the land on either side of the ocean. More southward fog may be expected, and is increasingly frequent the higher the latitude reached. This is attributed to the increase of gale frequency with latitude, the cyclonic systems causing rapid fluctuations in air temperature.

THE value for the latent heat of water is the subject of a note by Prof. A. Leduc in the current number of the *Comptes rendus* (January 2). He points out that, in spite of the fundamental importance of this constant, there is a difference of 1 per cent. between the 79·25 of Laprostaye and Deasins, confirmed by Regnault, and the 80·03 of Bunsen. He discusses the possible effect on these figures of the recent work on the variation of the specific heat of water, and shows that even after this is taken into account the difference is still of the same order. Substituting, however, 0·9176 for the density of ice at 0° C. for the 0·91674 found by Bunsen, the 80·03 of the latter investigator becomes 79·15. The larger number for the density of ice is that found by M. Leduc from his own researches, who thus arrives at 79·2 calories at 15° C. as the most probable value for the latent heat of water.

THE third part of "The Primary Arithmetic," edited by Dr. Wm. Briggs, has been published by Mr. W. B. Clive at 6*d*.

A COMPREHENSIVE catalogue of microscopes and accessories has just been issued by Messrs. W. Watson and Sons, High Holborn, W.C. Several of the instruments described and illustrated embody valuable modifications in constructional detail; and the requirements of all classes of workers are met by the two series of objectives—holoscopic and parachromatic—computed by Mr. A. E. Conrady, under whose supervision the whole of Messrs. Watson's optical work is now produced.

Two more subject-lists of works in the library of the Patent Office have been published. The first comprises books on heat and heat-engines (excluding marine engineering), and the second deals with works on aërial navigation and meteorology. Each list consists of two parts, a general alphabet of subject-headings, with entries in chronological order of the works arranged under these headings, and a key, or a summary of these headings shown in class order. These lists may be obtained at the Patent Office, Chancery Lane, W.C., at 6*d*. each.

THE *Bulletin of the Johns Hopkins Hospital* for December, 1905 (xvi., No. 177), contains the second of the Herter lectures by Prof. Hans Meyer on the contributions of pharmacology to physiology, several medical and surgical papers and reports of societies, and some interesting extracts from medical reports by Dr. Wiesenthal, a physician who lived in Baltimore in the latter part of the eighteenth century. The *Bulletin* is an admirable publication, and should be in the hands of all medical practitioners.

THE Science Press of New York has published an account of a research of Prof. E. L. Thorndike on the measurement of twins as the first number of a series of monographs to be known as "Archives of Philosophy, Psychology, and Scientific Methods," which are to be edited by Profs. J. McKeen Cattell and F. J. E. Woodbridge. This monograph presents the results of precise

measurements of fifty pairs of twins from nine to fifteen years old in six mental traits, and their bearing upon the comparative importance of heredity and environment as causes of human differences in intellectual achievement.

FIVE new volumes—Nos. 146 to 150 inclusive—of Ostwald's "Klassiker der exakten Wissenschaften" have been received from the publisher—Mr. W. Engelmann, Leipzig. No. 146 is a paper by Lagrange (1768), translated from the French and edited by Herr E. Netto, the title being "Über die Lösung der unbestimmten Probleme zweiten Grades." J. B. Listing's "Beitrag zur physiologischen Optik," edited by Prof. O. Schwarz, forms No. 147 of the series; and a lecture delivered at Vienna by E. Hering in 1870, "Über das Gedachtnis als eine allgemeine Funktion der organisierten Materie," constitutes No. 148. Under the title "Tastsinn und Gemeingefuhl," an article contributed by Dr. E. H. Weber in 1846 to R. Wagner's "Handwörterbuch der Physiologie" is reprinted with notes by Herr E. Hering. Of particular interest is the reprint (No. 150), edited by Herr A. von Oettingen, of Fraunhofer's paper entitled "Bestimmung des Brechungs- und Farbenzerstreuungs-Vermögens verschiedener Glasarten, in bezug auf die Vervollkommnung achromatischer Fernröhre." This volume contains a plate showing Fraunhofer lines in the solar spectrum, and a picture of the statue of Fraunhofer at Munich.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c* (GIACOBINI).—Observing at Sunderland on December 22, 1905, Mr. Backhouse estimated that the magnitude of comet 1905*c* was approximately 8·3, at 18h. 40m. G.M.T., the observation being made in faint twilight; its diameter he found to be $5\frac{1}{2}'$.

As this comet now rises but about an hour before sunrise, and the apparent distance from the sun is decreasing, it will be scarcely possible for further observations to be made before February, when the comet should again become visible, possibly to the naked eye, in the evening sky.

EPHEMERIS FOR HOLMES'S COMET (1892 III., 1899 II.).—The following search-ephemeris for Holmes's comet is published by Herr H. J. Zwiers in No. 4063 of the *Astronomische Nachrichten*:—

oh. G.M.T.

1906	α (app.) h m s	δ (app.) ° ′ ″
January 11	21 5 39	−18 59 53
,, 13	21 9 45	−18 30 19
,, 15	21 13 51	−18 0 25
,, 17	21 17 57	−17 30 13
,, 21	21 26 7	−16 28 55
,, 25	21 34 15	15 26 26
,, 29	21 42 21	14 22 49

In referring to the ephemeris for comet 1892 V. in these columns last week, that object was designated, by mistake, Holmes's comet. Both bodies were discovered at about the same time, and their periods are very similar, but comet 1892 V. is the faint one discovered by Prof. Barnard, by photography, on October 12, 1892, and was not seen on its return in 1899. A report that it has been detected at the La Plata Observatory is as yet not confirmed.

On the other hand, Holmes's comet was bright enough in 1892 to be observed with the naked eye, and, owing to its eccentric fluctuations in brightness, was described by Prof. Barnard as certainly the most remarkable comet he had ever seen, taking everything into consideration. During an interval of fourteen minutes its diameter, as observed with the 36-inch refractor, increased from $43''·4$ to $47''·9$, and the comet became perceptibly brighter whilst under observation. This comet was first seen on its return in 1899 by Prof. Perrine on June 10 of that year. According to the above ephemeris, the comet should set about ninety minutes after sunset on January 11, but probably its low declination will make it a difficult object to find.

PHOTOGRAPHS OF THE SOLAR GRANULATIONS.—Using the astrographic telescope of the Pulkowa Observatory, Prof. Hansky has obtained some exceedingly interesting photographs of the solar granulations and spots on a large scale. The solar image at the focus of the instrument has a diameter of 3 cm., and by the use of an achromatic double concave lens was enlarged up to 54 cm. (about 21 inches).

The negatives thus obtained were photographically intensified by repeated copying, and details of the granulations became visible. Portions of the strengthened images were then enlarged to such a scale that the solar diameter would be equal to 6 metres (*i.e.* nearly 20 feet).

Copies of the sections thus enlarged are reproduced in the bulletin issued by Prof. Hansky, and on comparing two which were taken with an interval of twenty-five seconds it is seen that the granulations have undergone but little change, although relative movement and changes in brightness are discernible. Photographs taken with an interval of one minute show great changes, and after three minutes only one or two of the granules are recognisable.

The dimensions of the granules vary considerably; the smallest measured had a diameter of about 670 km., the largest about 2000 km.

Prof. Hansky intends to prosecute this research further, and hopes thereby to solve several questions regarding the periodic appearance of granules, the effects of their movements on spots and faculæ, &c.

THE ORBIT OF ξ URSÆ MAJORIS. On many grounds the determination of the correct orbit of the double star ξ Ursæ Majoris is of great interest and importance, and for this reason M. N. E. Nörlund, of Copenhagen, has made a very careful re-investigation of the available data and measurements. About eighteen orbits have been computed previously.

The results of this investigation are given in No. 4064 of the *Astronomische Nachrichten*, and the places computed from the elements obtained are compared with those obtained by many different observers.

For the period M. Nörlund obtains 59·8096 ± 0·06 years, for the time of periastron 1815·957, for the distance $a = 2''·5128$, and for the eccentricity of the orbit $e = 0·4108$.

THE INTERNATIONAL FISHERY INVESTIGATIONS.[1]

THE first of the reports referred to below is the first report of the British North Sea Investigations Committee on the International Fisheries Investigations. From time to time during the last three years in which the investigations have been in progress, the International Council has issued the "Bulletin des Resultats," in which are contained the results of the hydrographical and plankton investigations carried out on the periodic cruises; and also the series of "Publications de Circonstance," containing the results of incidental investigations carried out by the various naturalists on the staffs of the different committees. Quite recently, too, the council has issued the third volume of "Rapports et Procès-Verbaux," containing a *résumé* of the results obtained up to the present time. The present volume is, however, the first report which deals exclusively with the results obtained by the British vessels. It is a report to the Fishery Board for Scotland on part of the investigations made by the Scottish staff.

The first three papers in the report, written by Messrs. Helland-Hansen and Robertson, deal with the hydrography of the Færöe-Shetland channel and the adjacent sea regions—the area investigated by the Scottish vessels, H.M.S. *Jackal* and the *Goldseeker*. The principal Scottish line of hydrographical stations extends from the Shetlands to the Færöe Islands, and it is along this line that the changes taking place in the constitution of the sea-water can most easily be observed. It has long been known that the water in this region may be derived from various

[1] "Report on Fishery and Hydrographical Investigations in the North Sea and Adjacent Waters, 1902–3." Edited by D'Arcy W. Thompson. Pp. vii+618. [Cd. 2612.] (London: H.M. Stationery Office, 1905.) Price 8s. 9*d*. net.

"Report on Fishery and Hydrographical Investigations in the North Sea and Adjacent Waters, 1902–3." Report No. 2 (Southern Area). Edited by Dr. E. J. Allen. Pp. ix+377. [Cd. 2670.] (London: H.M. Stationery Office, 1905.) Price 8s. 9*d*. net.

sources. We have to deal first of all with the "Gulf Stream," or, as it is now termed, the "Norwegian branch of the European stream," which, originating in the Atlantic Ocean, flows north and east through the Scotland-Shetland and the Færöe-Shetland channels, sometimes reaching as far north as the Murman coast. A second component is water of Arctic origin which enters the Shetland-Færöe channel as an offshoot from the east Icelandic polar stream. Further, the hydrography of these regions is complicated by the occasional presence of water from the Norwegian Sea, from the coasts of Britain, or from the North Sea itself. These various components are traced by observations of their salinity, temperature, and plankton contents. The Norwegian branch of the European stream is shown to exhibit a well marked periodicity. In 1903 the inflow of Atlantic water through the Shetland-Færöe channel decreased from May on, and practically ceased in November, resuming in February of 1904. The southerly polar stream attained its greatest volume in spring; it is apparently able to make its way southwards at all seasons of the year, either as an undercurrent or at the surface. When it is strong it may obstruct the Norwegian stream in the Færöe-Iceland channel, and cause the latter to pass to a greater extent between Scotland and Shetland. These are the principal results attained so far, and they do not add much to our knowledge of the hydrography of these regions; but it must be remembered that they are founded on the results of one year's complete investigations only, and are best to be appreciated at the end of the five years' investigations and when they are considered along with the results attained by the other investigations now in progress.

A most important part of the original scheme of investigations was the discussion of the statistics obtained by the participating States. These matters receive proper attention in the present volume, and Prof. Thompson discusses in a very attractive manner an interesting series of statistics furnished by the Granton Steam Fishing Company, and a similar series of statistics given by the steam trawlers owned by Messrs. Johnston, of Montrose. In each case the average catch per vessel has been calculated, and tables and curves are given showing, in an interesting fashion, the seasonal fluctuations of the fishes under review, which are haddock, whiting, cod, plaice, turbot, and lemon sole. In the case of each fish there are generally two maxima of abundance, one of which is always well marked and the other not so well shown. In the case of the haddock there is, however, a very close correspondence between the catch of this fish and the surface temperature of the sea, a correspondence which Prof. Thompson points out is most probably due to the fact that the great summer fishery for herring takes place at the time when the surface waters of the sea have their greatest temperature, and when the haddock is shoaling to feed on the herring spawn. It is notable that in neither of these cases is there any certain indication of a progressive decrease or increase in the volume of the catches of any of the fishes in question.

Perhaps the most valuable paper in the volume is that contributed by Dr. Fulton in which he elaborates the method of studying the distribution and seasonal fluctuations of fishes first suggested by him in the reports of the Fishery Board for Scotland some years ago. This consists in obtaining accurate records of the catches made by a large number of trawlers, and also information of the places where these catches were made. This plan of obtaining commercial fishery statistics (apart, of course, from the ordinary official figures) was first practised by the Fishery Board, and a considerable number of Aberdeen steam trawlers now regularly provide these figures. The first results of these investigations were published in the annual reports of the Fishery Board, but they are now utilised in connection with the other investigations of the international organisation. The figures are collected by the statistical staff of the Fishery Board at the market in Aberdeen, and are expressed as the quantities of fish caught per vessel per 100 hours' fishing. The North Sea is divided into a number of squares, each of which is bounded by one degree of latitude and two degrees of longitude. All the catches of fish made on each of these squares during each month of the year are then brought together and expressed as the cwts. of fish caught per 100 hours' fishing on each area, and curves are constructed which are superposed, and so show in a very instructive manner the variation in the abundance of each kind of fish from month to month during the year. It is thus shown that there are two maxima of abundance for each fish during the year, one of which corresponds with the spawning time of the species. It is further shown that there is a "complementary or compensating fluctuation" among different species on the same ground, one species becoming abundant as another becomes scarce, so that the sum total of the species on the same ground remains nearly constant during the year.

Other reports in the same volume are those by Dr. T. Scott on the crustacea collected during the seasonal cruises of the *Goldseeker*, and similar papers by Mr. Clark on the other plankton collections. Prof. Thompson also contributes a translation of a paper by Sandstrom and Helland-Hansen on the mathematical investigation of ocean currents. It is regrettable that the fishery experiments of the *Goldseeker* have not been described and summarised in this volume, but these will no doubt be the subject of a future report. One must not omit to mention the beautifully engraved charts of the North Sea which illustrate the paper on the trawling statistics of Aberdeen.

The second of the reports under notice deals with the part of the international investigations which was entrusted to the Marine Biological Association, and gives an account of the researches carried out in the southern part of the North Sea and in the English Channel. In some respects this report is complementary to that issued by the Scottish Fishery Board; in the latter special attention is directed to the results of the hydrographical work and to statistical studies, while fishery investigations are not reported upon. In the English Blue-book, on the other hand, the bulk of the space is devoted to an account of the fishery investigations. The hydrographical researches, which are reported only by Mr. D. Matthews, were carried out in a somewhat limited area, but are of very great interest. It is shown that the water in the English Channel is derived from two main sources:—(1) high salinity water (35·6 parts per thousand and upwards), which enters the Channel as a current flowing in a northerly direction from the Bay of Biscay; and (2) low salinity water, entering the Channel as a southerly current from the Irish Sea and the Bristol Channel. The limits of these contributing currents are well shown on the hydrographical charts, where the lighter water is seen to be present mainly to the west of a line running roughly south from the Scilly Isles; while the denser water forms a tongue of variable magnitude, according to the season, entering the Channel in a north-easterly direction near Ushant. Within the Channel itself the hydrographical conditions are very complex; a general drift of surface water from west to east has been observed, but the distribution of the high and low salinity waters in the Channel is far from simple. Generally speaking, the main source of the water entering the Channel during the summer and early autumn is the Irish Sea, while during the rest of the year the denser water of the Bay predominates. The observations have been made for a year only, so that the very important question whether or not these changes in the origin of the contributing waters are periodic remains still to be investigated.

Perhaps the most interesting part of the report is that by Mr. Garstang dealing with the results of experiments on the marking and liberation of living plaice and other fishes. These experiments have now been carried out by most of the national research staffs, and are yielding results which are very instructive from the point of view of the growth and migrations of the plaice especially. The mark used is a brass label bearing a number, and fastened to the body of the fish by means of a silver wire passing through the body and attached to the other side by a bone button. This mark can be attached to the fish without permanent injury to the latter, and apparently without any retardation of growth or other disturbance of the normal habits of the fish. The results are recorded in Mr. Garstang's report, and are illustrated by means of synoptical charts which show the principal migrations made by the fishes which have been recovered. Up to the end

of 1903, 1463 plaice were marked in this way, and of these 287, or 19 per cent., have been returned to the association. The general facts regarding migrations brought out by these experiments are these:—the smaller fishes do not appear to migrate to any considerable extent, and the larger the fish is the more extensive are its migrations. In some cases the distance travelled has been very considerable; thus one plaice is shown to have travelled a distance of 175 miles in about six weeks, and another travelled a distance of 210 sea-miles in eight months. The general trend of the migrations has been in a southerly direction during the winter and in a northerly one during the summer. As a rule, the smaller fishes travel from the shallow water "nurseries" to the deeper waters during the earlier period of their life.

A most attractive part of these migration experiments is the question of the transplantation, on a commercial scale, of fishes from overcrowded grounds to those grounds where the conditions for favourable growth are present, but where there is not already an abundant population of the kind of fish in question. An interesting account of such an experiment is given by Mr. Garstang. Although the conditions of nutrition on the well known Dogger Bank are apparently very favourable for plaice, yet, on account of its comparatively isolated situation, this area contains a population of plaice which is probably far below that which it is able to support. Accordingly, more than 1000 small plaice were transplanted from certain in-shore grounds to the Dogger Bank, and in the course of a year more than 40 per cent. of these fishes were re-captured from the Bank itself and the slopes around it. It is shown that the growth-rate of these fishes was far in excess of that of those living on the ordinary in-shore fishing grounds, and the question of the practicability of the wholesale transplantation of small plaice from the shallow-water fishing grounds to such grounds as the Dogger Bank is carefully discussed. It is very questionable, however, whether transplantation operations on such a scale could be arranged at all so as to be successful.

The remainder of the report deals with the records of the fishing experiments and with various other matters. Dr. Wallace presents a report on the growth-rate of the plaice based on the examination of the annual growth-rings in the otoliths. Mr. Todd contributes a lengthy account of his examination of the contents of the stomachs of a very great number of fishes caught in the course of the trawling operations, and draws some interesting conclusions on the food of the various species dealt with. Lastly, Mr. Gough reports on the occurrence and distribution of the plankton of the English Channel during 1903.

The records of the trawling experiments contain a large mass of observations which are capable of much further analysis than has been attempted in the present report. 84,000 measurements of individual fishes have been made in the North Sea and in in-shore waters, and when these are considered along with the records of the hauls made by the Scottish Fishery Board's exploring steamer abundant material should be forthcoming for a discussion of the distribution of fishes in the North Sea according to their age and size. Altogether the North Sea Fisheries Investigation Committee is to be congratulated on the publication of these reports.

J. JOHNSTONE.

INSECT PESTS OF THE COTTON PLANT.[1]

THESE two reports may be taken as object-lessons of the way in which such economic investigations should be carried out by the agricultural departments of progressive countries.

The wide area over which cotton cultivation is spreading makes the investigation of its enemies in those regions where it has long been cultivated of great value. Such researches guide us in investigating new enemies, and they prepare us to guard against the introduction of pests with foreign seed.

The authors of the report on the bollworm have produced a work of great value to all cotton planters. The pest is recorded from North and South America, the West Indies, Europe, many parts of India, China, and Japan, the East Indies, Australia and New Zealand, and even in the Gilbert and Navigator Islands. Of particular interest is the record from the Sudan and British East Africa, but it is not recorded as attacking cotton there. Besides infesting cotton, it is equally destructive to corn, and the authors tabulate seventy other food plants, distributed over twenty-one natural orders.

There are excellent plates showing ova, larvæ damaging the buds, tassels and ears of sweet-corn as well as cotton. The injuries are explained, and it is clearly pointed out how the cotton becomes infested by the third and fourth

FIG. 1.—Work of Bollworm in Cotton Bolls. 1, Bollworm eating into a half-grown cotton boll; 2, bollworm boring into a full-sized cotton boll; 3, full-grown bollworm and its work in large cotton boll; 4, cotton boll only partially destroyed by bollworm, two "locks" open, the others destroyed (original).

generations of larvæ, the previous ones feeding upon the corn.

The summary given of the life-history shows that the moth may lay from 500 to 3000 eggs, especially upon the "silks" of corn and the "squares" of cotton. During warm weather they hatch in two or three days. In spring the young larvæ eat the buds, later the silks and tassels of the corn; in August and September they attack the cotton. They bore directly into the "squares" and "bolls," and destroy the latter. Maturity is reached in two weeks; they then enter the soil to pupate. Detailed descriptions are given of all the stages, the effects of climate, and variations in colour. Nothing definite is shown to account for the great variation seen in the larvæ.

[1] "The Cotton Bollworm." By A. L. Quaintance and C. T. Brues. U.S. Department of Agriculture, Bureau of Entomology, *Bull.* 50. Pp. 155+plates xxv+figs. 27. (1905.)
"The Mexican Cotton Boll Weevil." By W. D. Hunter and W. E. Hinds. *Idem, Bull.* 51. Pp. 181+plates xxiii+figs. 8. (1905.)

Amongst predaceous enemies is mentioned a Chrysopa which feeds upon eggs and young larvæ. Wasps appear to do most good. Numerous parasites are also described; one, *Trichogramma pretiosa*, a small hymenopteron, attacks the eggs, others the larvæ; but from what we

FIG. 2.—Various Results of Larval Work. 24, Leaf fed on extensively by weevils in confinement; 25, full-grown larva in square ready to bloom; 26, full-grown larva in square of usual size; 27, larva full-grown, ovary in square entirely destroyed; 28, larva full grown, ovary untouched—all reduced (original).

gather from the report man cannot expect much help from these "natural checks." Remedial and preventive cultural measures are thus fully explained.

The Mexican cotton boll weevil is luckily confined to the United States, Mexico, Cuba, and Guatemala. The authors have been unable to verify the reports that it has been found in Africa or Brazil. If a cotton weevil occurs in the former country it is probably another species, as we see is the case in the Philippine Islands.

The Mexican weevil has the unique record of developing in less than twenty years from an obscure species into a great pest. The authors ably describe its life-history and destructive habits in Texas and elsewhere. In the summary of the life-history it is stated that the egg is deposited by the female in a cavity formed by eating into a square or boll. The egg hatches in a few days, and the footless grub begins to feed, making a larger chamber for itself as it grows. The pupa also occurs in the boll. It is important to note that no other food than cotton has been found.

Some interesting experiments are recorded which tend to show that the weevils are not able to locate their food by smell.

Another series of experiments showed that the weevils prefer Egyptian cotton (Mit Afifi) to the American upland cotton.

Their capacity for reproduction seems appalling, judging from the table given showing the annual progeny of one pair of hibernating weevils, which amounts to 12,755,100!

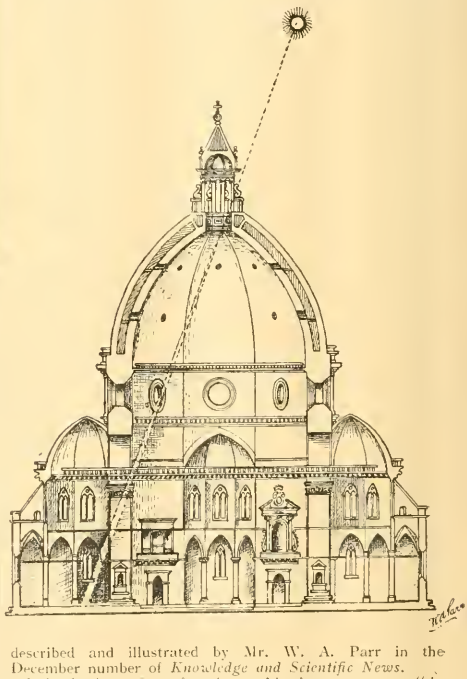
The beetles hibernate in many places, as in infected bolls and stalks, and it is shown that the early destruction of the stalks in the fall is the most effective way to reduce the pest.

Dissemination takes place in cotton in bales and that sent for "ginning." Shipments of seeds are said to be almost certain to carry weevils if coming from infested areas. The report also shows another important point, namely, that the pilosity of the plant affects the progress of the weevil. Parasites do not seem to be of much use. Doubt is cast by the authors upon the benefit of *Pediculoides ventricosus*. Mention is also made of the possible use of the Mexican ants (*Ectotomma tuberculata*), &c. Of great importance to those who import seed is the result showing that bisulphide of carbon is the best substance to clean the seed.

FRED. V. THEOBALD.

THE GREAT GNOMON OF FLORENCE CATHEDRAL.

ALTHOUGH numerous Christian churches are either oriented or adorned with reference to some astronomical phenomenon, there are few of such direct interest to the astronomer as the magnificent cathedral of Florence, which contains a gigantic contrivance for determining the advent of the summer solstice. We refer to the famous gnomon, placed in the dome of that cathedral by Paolo Toscanelli about the middle of the fifteenth century, and



described and illustrated by Mr. W. A. Parr in the December number of *Knowledge and Scientific News*.

Lalande in 1765 referred to this instrument as "la méridienne que l'on voit dans la Cathédrale de Florence est le plus grand monument d'Astronomie qu'il y ait au

monde," but at that time the astronomical significance of the Egyptian temples, or even of our own less pretentious Stonehenge, had not been demonstrated.

Sir Norman Lockyer has shown in "The Dawn of Astronomy" that the enormous edifice at Karnak, the temple of Amen-Ra, was oriented for a similar purpose, so that at the setting of the sun on the day of the solstice, and at that time only, the solar beam flashed along the darkened axis of the temple, some 500 yards long, and illuminated the "holy of holies" wherein the priest was ready to fulfil the rites of "the Manifestation of Ra." He has also shown that Stonehenge was erected for a similar purpose about the year 1680 B.C., but in this case the limb of the actual (rising) sun was observed, the avenue simply forming the sight-line to the point on the horizon where the sun-god would make his first appearance on the day of the solstice.

But although since Lalande made the statement quoted above it has been shown that the gnomon at Florence is not the *largest* monument to astronomy the world has ever seen, it is still one of the most interesting. As may be gathered from the accompanying illustration, the sunlight, passing through the southern window of the lantern, falls on to the gnomon, which is built into the marble sill of the window, and thence, through a circular orifice, on to a "solstitial" marble slab let into the cathedral floor some 300 feet below, where its correct position at the solstice is marked, or was intended to be marked.

This immense meridian instrument was probably designed by Toscanelli in order to provide exact observations for the correction of the Alphonsine tables which were then in use, but which represented very inadequately the solar motion, more especially as regards the true length of the tropical year. Whether he also intended to observe the variation of the obliquity of the ecliptic is a much discussed question, but it does not seem improbable. In either case his gnomon, probably built only in 1468 A.D., could not answer this purpose anything like so surely as do the Amen-Ra and Stonehenge structures, built many centuries earlier. Apart from this reason, the facts that the gnomon itself has been removed from its original position, and that the solstitial circle on the cathedral floor has been found to be erroneously placed, have destroyed for ever the instrument's utility in this direction. It has been used, however, in order to detect any possible movement in the fabric of the cathedral, but, to the credit of Brunelleschi, who built the structure, no such movement has ever been demonstrated.

In the light of the recent articles in NATURE (p. 153) concerning the fires, &c., by which the ancient British festivals were celebrated, it is interesting to note that Mr. Parr considers that the great display of fireworks, which to the modern Florentine forms the chief attraction of the Midsummer Day festival, is simply the analogue of the "St. John's Fires" kindled in former times to celebrate the advent of the summer solstice. On that day huge crowds of Florentines flock to the cathedral in order to celebrate the festival of their patron saint, St. Giovanni, and at night the great dome itself is illuminated.

W. E. R.

THE TRAINING OF THE BODY AND MIND.

FOR years the London County Council has arranged a conference of teachers during January, and this time it was held on January 4–6 at the Medical Examination Hall on the Victoria Embankment. In the old days, when the County Council was only interested in technical instruction, the meetings were devoted to the interests of science teachers more particularly, but now that general education has been added to the responsibilities of the body that governs London, matters appertaining to all kinds of teaching are considered at the conferences.

The first day's work was, however, devoted to a subject that affects all education, namely, that training of the body which is correlated with the proper development of the mind. Mr. A. J. Shepheard (vice-chairman of the education committee of the London County Council), who opened the conference, urged the importance of a complete education, and Colonel Malcolm Fox (inspector of physical training to the Board of Education) read the first paper, which dealt more particularly with physical training in elementary schools. He began with a brief sketch of the history of gymnastics and physical culture in general, though going no further back than the days of ancient Greece, which, in its beautifully symmetrical statues, has left us undoubted evidence that it had little to learn in the science of training the body.

Colonel Fox went on to say that the Greeks practised little of what we understand as gymnastics, and attained their object by such exercises as riding, dancing, leaping, or running, and he pointed out that the trend of gymnastic opinion is again turning strongly in the same direction. As the power of Greece declined, her universal physical culture ceased to be national, and passed to the individual whose business it was to afford entertainment by exhibiting his prowess in the arena. When the remnants of greatness passed to Rome, no physical training became general, as the many contented themselves with the excitement afforded by the efforts of the trained few. It is true that the "sporting nobles" of the famous Tenth Legion used from time to time to descend into the arena, competing with some favourite team in the chariot races, or matching their skill with sword and shield against the net and trident. This action was, however, exceptional, and the period bears the picture of a vast concourse hanging with fevered excitement on every stroke of sword or cast of net—spectators at a game that they themselves had little ability or desire to play. To find a modern parallel to such a scene we have unfortunately not far to seek.

After touching on the absence of any definite system of gymnastics also in the middle ages, and the recommendation of exercises as a cure for certain complaints as early as the sixteenth century, the reader of the paper traced the use of systems in France, in Germany, where gymnastics were first used in an educational sense, in Switzerland, where Pestalozzi adopted them, and in Sweden, where between 1776 and 1839 Ling was the pioneer in classifying gymnastics into groups and arranging them scientifically in accordance with the needs of the human body.

Colonel Fox described how, after an interregnum, revivals of physical training took place, and stated that under the tests of modern physiological knowledge the Swedish system of Ling stands out preeminently above all others. He further dwelt on the mild and gradual work in its early stages, on its effects upon the body and success in other countries, as well as its educational results. These admit of no immediately apparent proof, but they do exist, as a few weeks' trial of them will most assuredly show. Psychology, Coloned Fox said, with our limited knowledge, allows of deductions only from experience, and the latter is unanimous that the educational results claimed by Ling are gained, and that the qualities of courage, obedience, decision, alertness, concentration of thought, and self-confidence are not confined to the hour or two of the gymnastic lesson, but become part and parcel of the child's nature.

After speaking of methods, duration of lessons, the dearth of male teachers, and matters of interest to elementary and other teachers, Colonel Fox concluded by quoting figures from the report of a Royal Commission on Physical Education in Scotland. Of 600 children examined in Aberdeen, only 326 were found to be in good health, while of the same number in Edinburgh but 171 were found to be sound.

The next paper was by Mr. W. Langbridge (headmaster of Wolverley Street School, Bethnal Green), and dealt with exercises which can with advantage be performed in classrooms and afford a relief to ordinary lessons during which activities are constrained.

In the afternoon Sir Lauder Brunton took the chair, and discussed education in connection with the threefold character of man. At first, he said, moral training was provided, and churches and cathedrals were built long before the people could read or write; then mental culture was considered, and became very general; and, lastly, it was being recognised that the condition of the body had considerable effect upon the morals and the mind, so that a physical training was also considered necessary. He gave some interesting instances to show how character

and habits had been entirely altered by accidents to the brain, and said that while Newton was physically weak, Young, who was his superior even in mental capacity, was a circus rider, and could perform almost any bodily feat.

Sir Lauder Brunton spoke of the need to train the higher inhibitory nerve centres, and of the possibility of keeping in order involuntary movements. He said that children could not do physical exercises unless they were properly fed, and urged that no damage must be done by over-exertion. Medical inspection was desirable, but teachers, he thought, could easily learn to recognise the signs of danger.

Dr. Kerr (medical adviser to the London County Council Education Committee) took as his subject the position of physical exercises in the infant department of the elementary school. He pointed out that while certain of the nerve cells in the infant were quickly matured, and this was especially so with those dealing with behaviour that has been hereditary for long periods, other nerve cells were still capable of being acted upon for a considerable time. In this state they were very susceptible to fatigue, and frequent periods of rest were needed in which the waste products from action could be removed. He advised the use of physical exercises for infants, and maintained that no great perfection of detail ought to be looked for.

Of a different character was Mrs. Kimmins's paper on the educational value of organised play, for it was a graphic account of the way in which most of the benefits claimed as coming from physical training could be gained out of school, and in the particular case described, away from it.

All the speakers upon physical exercises agreed that these were only complementary to games; and in the last paper of the day Miss Kingston (organising instructor of physical exercises of the London County Council) discussed the interrelation of drill and organised play.

It should be pointed out that all concerned were most anxious that the word drill should not be used, as it called up in the mind military drill, something quite different from the exercises and unfitted for children. There was also considerable unanimity as regards the need for the pupils to do the work for its own sake and as a pleasure, and not as a task. Sir Lauder Brunton was most emphatic on this point, as was also Dr. Kerr. The Rev. Stuart Headlam, a member of the old School Board, in the discussion objected to things being made too pleasant, but it had been pointed out that even games pall if they are too much organised, and their interest and freshness thus lost.

There is no doubt but that as true nature-study should properly put the child so far as possible into the same mental relation with its surroundings that primitive man enjoyed, so physical exercises adopted in a pleasurable way should counteract the baneful effects of civilisation, as Dr. Kerr pointed out on Thursday, and, one may add, give our young people the bodily advantages of their remote ancestors.

As on previous occasions, Mr. C. A. Buckmaster and Dr. Kimmins (chief inspectors, respectively, to the Board of Education and the London County Council, education committee) organised the conference in a remarkably successful manner. WILFRED MARK WEBB.

COLOUR VISION IN THE PERIPHERAL RETINA.[1]

THE results of a research into the nature of colour vision in the peripheral portions of the retina, carried on by Mr. Baird during the years 1903 and 1904 in the psychological laboratory of Cornell University, have lately been published in a pamphlet. The work so carefully done by Hess and the numerous papers by him on this subject have received fairly general acceptance, and in the present work Mr. Baird confirms most of Hess's conclusions. The reason he gives for the publication of a pamphlet which contains little new work of any great value is that Hellpach, in his research on the nature of colour sensation in the peripheral retina, had arrived at conclusions which controverted many of the statements of earlier observers, and it was deemed advisable to repeat Hellpach's work in order to see whether there might not be some fallacy in the method. Mr. Baird's work practically in every respect confirms that of Hess, and we think there is little doubt that his explanation of the confusing results obtained by Hellpach is correct, that Hellpach did not allow sufficient time to elapse between successive stimulations, and consequently the colour sensation due to the immediate stimulation was partly modified by a latent after image of the preceding stimulus.

In standardising his colours, Mr. Baird arrived at practically the same results as Hess. The red used transmitted no part of the visible spectrum, and Hess, in order to get a stable red, had to mix it with a certain amount of blue. The yellow, green, and blue used corresponded fairly exactly with Hess's stable colours.

It is when we come to the problem of equating the white values of the different colours that the greatest difficulty is met with. We must confess to a strong suspicion of the value of Mr. Baird's method. He is engaged on a research on the nature of colour vision in the peripheral retina, and in the determination of his standards he utilises the very portion of the retina which he is subsequently going to investigate. We quite allow that there is no satisfactory method of equating white values at present known, but we certainly think that Mr. Baird has chosen the least satisfactory of all. Probably the best method of photometry available at present depends on the flicker phenomenon, and for Mr. Baird's purpose we feel sure it would have been much more suitable and much more scientific than the method he did adopt.

In other respects the work has evidently been carefully done, and though, as we have said, it adds little that is new to our stock of knowledge, it is of value in that it confirms much of the work of previous observers.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. R. A. LEHFELDT, professor of physics at the East London College, has been appointed to the chair of physics in the Transvaal Technical Institute, Johannesburg.

THE Corporation of Glasgow has resolved to make a grant of 10,000*l.* to the building fund of the Glasgow and West of Scotland Technical College, from the common good of the city.

IT is satisfactory to find a committee of the Classical Association reporting that "in view of the legitimate claims of other subjects the amount of time devoted to the classics on the classical side of boys' public schools is as great as can reasonably be expected." From the report which was presented at a meeting of the association on Saturday last, it appears that in the highest form on the classical side in the larger public schools a considerable amount of specialisation is allowed to many boys. In the other forms the time devoted to Greek and Latin together generally amounts to about one-half of the whole number of school hours. In the smaller public schools there is less specialisation in the highest form. The proportion of time given in school to classics increases from somewhat less than one-third in the lowest form in which both Greek and Latin are studied to slightly less than two-thirds in the highest form. The committee suggested that time and effort might be saved and better results obtained by certain changes in the method of teaching Greek; and in the discussion upon the resolutions put forward with this end in view, we are glad to see that Canon Lyttelton, headmaster of Eton, pointed out that the time gained by the adoption of the plan proposed "might well be given to instruction in some of the elements of scientific knowledge rather than to history and archæology. Let them hold out a helping hand to their scientific colleagues and meet them half-way. There had been too little conciliation between the two sections of teachers. Then we might hope to correlate these great subjects, which were too important to abandon, but which we had not yet enabled to live in amity together."

THE organisers of the North of England Education Conference, held this year at Newcastle-upon-Tyne on January 5 and 6, had to struggle with the fact that almost all persons and bodies who were desirous of conferring together had their hands full with the difficulties of primary education and its immediate continuations. The conference was well attended by between two and three hundred members drawn chiefly from the education committees of the county councils, the permanent officials of such committees, and schoolmasters and mistresses, and their interest was almost entirely directed to the problems called into existence by the duties now thrown upon the education committees. Not a word was said as to higher education, very little as to secondary education in any form, and, it may be added, scarcely a word as to the religious difficulty. The tone of the conference was distinctly optimistic, and it was the general opinion that if the councils were less encumbered by intervention of the Board of Education, and deputed more of their own work to persons in each locality, the difficulties that have declared themselves would work themselves out. It was encouraging to see so much determination to cope with the questions, in spite of the heavy tax of time thrown upon the education committees, and it is very clear from the local patriotism exhibited that the councils will not ultimately rest content with perfecting a primary system. It is, however, a question of pounds, shillings, and pence, and so long as the councils are left without other resources than the rates it is clear that improvements must wait a long time.

THE December, 1905, issue of the *Bulletin of the Massachusetts Institute of Technology* comprises, as usual, a list of the staff and students of the institute, with a statement of the requirements for admission, a full description of the courses of instruction, and an account of the Lowell School for Industrial Foremen. It is interesting to note that the institute offers summer instruction during the months of June and July, supplementing the work of the regular school year. Summer courses are undertaken primarily for the benefit, first, of those who wish to distribute their work over a larger portion of the year, or to gain more time for advanced work; and, secondly, of those who, through illness or other causes, have deficiencies to make up. Moreover, to bring students into closer relations with the practical side of their professions, professional summer schools are held in the departments of civil engineering, mining engineering and metallurgy, architecture, chemistry, and geology. The students, accompanied by instructors, give their time to field-work, or visit and report on mines and industrial establishments. The Lowell School for Industrial Foremen is a free evening school which includes, at present, mechanical and electrical courses extending over two years. These courses are intended to bring the systematic study of applied science within the reach of young men who are following industrial pursuits and desire to fit themselves for higher positions, but are unable to attend courses during the day. This number of the Bulletin, with its 408 pages, provides abundant evidence of the excellent work being accomplished by this widely known institute.

THE annual meeting of the Geographical Association was held on January 5, when the report for 1905 was adopted. The report shows that the total membership of the association is 503, including teachers of every grade, school inspectors, and others interested in geographical education. An important advance was made during the year by the formation of local branches. This is a valuable expansion of the work of the association, enabling members to meet at more frequent intervals, to discuss the advantages presented by their own district for teaching geography, permitting combination in excursions and cooperation in the accumulation of lantern-slides and other materials necessary for good teaching. The geographical exhibits collected by the association in 1904 were on view during the year at Liverpool, Huddersfield, Bedford, and Oxford. Part of the exhibits were lent to Felsted School for a local exhibition. The exhibition is now being broken up, and exhibits lent to the association returned. Dr. G. R. Parkin, secretary of the Rhodes Scholarship Trust, who was in the chair, dealt in his address with the general question of geography. In war, he said, geography is of the greatest importance. If our commanders at the battle of Colenso had possessed an elementary knowledge of the geography of the country thousands of precious lives might have been saved. In a nation like ours, which may any day find it necessary to send an expedition to a frontier place in India or to some corner of Africa, the intimate study of geography is an essential condition of national safety and honour. In commerce, too, geography is everything. Only last year the great cotton districts of Lancashire began to realise that the supplies of cotton were not sufficient for the demand, and Sir Alfred Jones organised a company to discover what places under the British flag are suitable for raising cotton. This is largely a geographical work which a great commercial country like ours should be carrying on as a Government measure. As the great workshop of the world, which almost requires the world from which to draw raw material and food, no nation ought to know so much about geography as ourselves, and yet up to the last eight or ten years hardly a subject has been shown so little consideration.

SOCIETIES AND ACADEMIES.

LONDON.

Zoological Society, December 12, 1905.—Mr. Howard Saunders, vice-president, in the chair.—*Exhibitions.*—Twelve enlarged photographs of whales taken at the fin-whaling factories in east Finmarken in 1883–89: A. H. **Cocks.** The species represented were *Megaptera longimana, Balaenoptera sibboldii, B. musculus,* and *B. borealis.*

The tail-vertebræ of a dormouse of the genus Eliomys, which showed the phenomenon, hitherto unrecorded among Mammalia, of the regeneration of a bony structure in case of accident: Oldfield **Thomas.** The caudal vertebra, in this case the twelfth, which had been originally broken across, had grown out into a slender styliform appendix 15 mm. in length and rather less than 1 mm. in diameter, the normal vertebræ of this part of the tail measuring about 6×2 mm. On further search two other specimens exhibiting the same structure had been found, and it appeared, therefore, that dormice, like lizards, were able partly to regenerate their tails, when these important balancing-organs got accidentally broken.—Microscopic sections of the skeletal tube found in the restored tail of one of the dormice (Graphiurus) exhibited by Mr. Thomas: Dr. W. G. **Ridewood.** The wall was made up of close-set lamellæ, producing in a transverse section a fine concentric striation. Lacunæ with numerous branching canaliculi were disposed regularly in relation with the concentric striations, and the general effect was that presented by a transverse section of the humerus or femur of a frog. Internally to the bony layers, and contiguous with the central jelly, was a moderately thick layer, which was clear, homogeneous, and highly refractive. Dr. Ridewood also exhibited, by way of contrast, slides of the skeleton of the restored tail of an iguana lizard, the skeletal tube in this case being composed of calcified fibro-cartilage and not of bone.—*Papers.*—Observations and experiments on the habits and reactions of crabs bearing sea-anemones in their claws: Prof. J. E. **Duerden.**—Notes on a large collection of snakes made by Mr. Alan Owston in Japan and the Loo Choo Islands: Captain F. **Wall.**—A collection of South Australian spiders of the family Lycosidæ contained in the museum at Adelaide: H. R. **Hogg.** Thirteen species were remarked upon, ten of which were described as new.—A collection of mammals obtained by Colonel A. C. Bailward during a shooting trip through Persia and Armenia during the past summer, and presented to the National Museum: Oldfield **Thomas.** Thirty-one species were enumerated, and special attention was directed to the discovery of Calomyscus, a primitive murine, the only ally of which, amongst recent forms, was the North American Peromyscus.—The colour-variation of the beetle *Gonioctena variabilis*: L. **Doncaster.** The material on which the paper was based was collected almost entirely at Granada, and the author found that, although the insect was extraordinarily variable, when a large collection was examined the beetles could be classified into two chief

groups with but few intermediate forms.—Two new species of worms, one a Pontodrilus from the shores of the Red Sea, and the other an Enchytraeid of the genus Henlea from India, which was destructive to the eggs of the locust: F. E. **Beddard.**—Two species of decapod Crustacea, a crab and a prawn, collected by Dr. R. Hanitsch, of Singapore, from a small artificial fresh-water pool on Christmas Island: Dr. J. G. **de Man.** The interest of their occurrence lies in the fact that previous to the construction of the reservoir, a few years ago, there seems to have been no possible habitat for these animals on the island, and they must have been introduced since that time, perhaps by migration from the sea. The crab was referred to *Ptychognathus pusillus*, a species described by Heller from the Nicobar Islands forty years ago, and not since found. The prawn was made the type of a new variety of *Palaemon lar*, both the variety and the typical form having a wide distribution in countries bordering the Indian Ocean.—Results of experiments made in connection with the heredity of webbed feet in pigeons: R. **Staples-Browne.**—New and rare British Oribatidæ: C. **Warburton** and N. D. F. **Pearce.** Eleven species were remarked upon, of which seven were described as new to science, and two were recorded for the first time as being British. The nymph of *Serrarius microcephalus* was described for the first time, and it was pointed out that *Gustavia sol* of Kramer was a nymph of an unknown species of Serrarius.

Royal Meteorological Society, December 20, 1905.—Mr. R. Bentley, president, in the chair.—Attempt to fly kites for meteorological purposes from the mission ship attached to a deep-sea fishing fleet in the North Sea: G. C. **Simpson.** These observations, which were made in July and August last, were carried out on behalf of the joint kite committee of the Royal Meteorological Society and of the British Association. By the kindness of the Royal National Mission to Deep-sea Fishermen, the kites were flown from the deck of the mission ship *Queen Alexandra* attached to the Red Cross Fleet. Owing to the vessel being almost continuously employed in trawling, the opportunities for flying kites were very limited; nevertheless, Mr. Simpson was able to secure eight ascents during the time he was on board the vessel, and he now gave the results obtained. The greatest height reached was 5800 feet.—Method of flying kites in Barbados in April and May last year: C. J. P. **Cave.** Mr. W. H. Dines, who had examined the records, said that the humidity traces show generally a value of about 60 per cent. at the surface, rising to 80–90 per cent. at heights from 1000 feet to 2000 feet, and then falling off again in some cases to 50 per cent. or less as the height increases. These values are lower than might have been expected over a tropical ocean. The increase is of the ordinary kind, but the maximum value occurs at a far lower elevation than is the case in Europe. It is probable that the relative humidity forms an extremely accurate index to the vertical circulation, a low humidity indicating a descending current of air, and so it may be inferred that there is some settling down of the atmosphere over the region of the smaller west Indian islands in April and May.—Temperature observations during the partial solar eclipse, August 30, 1905: W. H. **Dines.**—Comparison between Glaisher's factors and Ferrel's psychrometric formula: J. R. **Sutton.**—A rapid method of finding the elastic force of aqueous vapour, &c., from dry and wet bulb thermometer readings: J. **Ball.**

Chemical Society, December 21, 1905.—Prof. R. Meldola, F.R.S., president, in the chair.—Azo-derivatives from methyl-α-naphthocoumarin: J. T. **Hewitt** and H. V. **Mitchell.** Several of these derivatives are described; the most interesting is p-*nitrobenzeneazomethylnaphthocoumarin*, which gives an intense blue coloration in alkaline solution.—The preparation and reactions of benzoyl nitrate: F. E. **Francis.** Benzoyl nitrate is formed by the interaction of benzoyl chloride with silver nitrate at low temperatures. It is a light yellow oil which, if carefully warmed, decomposes into benzoic anhydride and oxides of nitrogen, but if heated quickly explodes.—The supposed identity of dihydrolaurolene and of dihydro*iso*laurolene with 1 : 1-dimethylhexahydrobenzene: A. W. **Crossley** and N. **Renouf.** Zelinsky and Lepeschkin supposed that these three substances were identical, but this is not the case.—The diazo-derivatives of 1 : 5- and 1 : 8-benzenesulphonylnaphthalenediamines: G. T. **Morgan** and F. M. G. **Micklethwait.**—Further experiments on a new method of determining molecular weights: P. **Blackman.**—Studies in fermentation. The chemical dynamics of alcoholic fermentation by yeast: A. **Slator.** The results indicate that the reaction, measured by observing the change in pressure due to evolution of carbon dioxide, is the slow decomposition of a compound produced by the interaction of the enzyme and the sugar.—Some new platinocyanides: L. A. **Levy** and H. A. **Sisson.** Hydrazine and hydroxylamine platinocyanides are described.—An intramolecular change leading to the formation of naphthalene derivatives: E. F. J. **Atkinson** and J. F. **Thorpe.** Ethyl sodiocyanoacetate condenses with benzyl cyanide to form ethyl α-cyano-β-imino-γ-phenyl-*n*-butyrate. This, when treated with an equal weight of sulphuric acid, forms an intense green solution, which yields ethyl 1 : 3-diaminonaphthalene-2-carboxylate.—The relation of position isomerism to optical activity, V., The rotation of the menthyl esters of the isomeric dibromobenzoic acids: J. B. **Cohen** and I. H. **Zortman.** An account of certain physical constants, including the molecular rotations of the six isomeric menthyl dibromobenzoates.—Some derivatives of naphthoylbenzoic acid and of naphthacenequinone: J. O. **Orchardson** and C. **Weizmann.**—Ethyl β-naphthoylacetate: C. **Weizmann** and E. B. **Falkner.**—Contributions to the chemistry of the amidines. 2-Aminothiazoles and 2-imino-2 : 3-dihydrothiazoles. 2-Iminotetrathiazoles and 2-amino-4 : 5-dihydrothiazoles: G. **Young** and S. I. **Crookes.**—The action of water on diazo-salts: J. C. **Cain** and G. M. **Norman.** An extension of a method of investigation, already described, to diazo-salts from 2 : 4-dibromoaniline and dibromo-*p*-toluidine (*cp. Proc. Chem. Soc.*, 1905, xxi., 206).—Note on the atomic weight of nitrogen: A. **Scott.** A reply to Richards (*Proc. Amer. Phil. Soc.*, 1904, xliii., 116) showing *inter alia* that the recent work of Richards and Wells on the atomic weights of chlorine and bromine has cleared up the discrepancy between the numbers obtained by the author for the atomic weight of nitrogen (*cp. Journ. Chem. Soc.*, 1901, lxxix., 154).—The solubility of zinc hydroxide in alkalis: J. **Moir.** When zinc hydroxide dissolves in excess of caustic alkali, the phenomenon is essentially the production of an equilibrium between the alkali and the zincic acid, and no definite chemical compounds such as $ZnO,8KOH$ are formed.—The slow combustion of carbon disulphide: N. **Smith.** The reddish-brown deposit formed when carbon disulphide and oxygen are passed through a heated tube consists chiefly of an acidic compound $C_{16}H_6O_4S_9$. The silver and ammonium salts have been prepared.

PARIS.

Academy of Sciences, December 26, 1905.—M. Troost in the chair.—Researches on the insoluble potassium compounds contained in humic materials: M. **Berthelot.** Powdered wood charcoal, after careful extraction with dilute hydrochloric acid and water, was treated with dilute solutions of potassium acetate and calcium acetate, the constituents of the charcoal ash being determined before and after the treatment. The results are compared with those obtained previously in which the charcoal was washed with water only, and conclusions drawn as to the nature of the potassium salts existing in wood charcoal.—On a standard of light: J. **Violle.** A description of some attempts to establish a standard of light by utilising the constant temperature obtained by boiling silver and copper.—On a new petrographic type of certain leucotephrites from Somma: A. **Lacroix.**—New observations on the formation and the quantitative variations of the hydrocyanic principle of the black elder: L. **Guignard.** The amount of the glucoside falls off very slightly with the increase of age of the leaf. At the end of the vegetative period it does not pass into the stem, but remains in the leaf when it falls off, and hence cannot be regarded as a reserve substance.—The influence of some factors on experimental parthenogenesis: Yves **Delage.** Numerous chemical reagents can bring about experimental parthenogenesis, and the conditions may also be varied, but the

fundamental action or condition still remains to be determined. The variable results obtained with the same reagent under, apparently, the same experimental conditions are pointed out, showing the necessity of averaging a large number of experiments before drawing conclusions. The reagent which has given the best results is made up of sea-water, 3 c.c., solution of NaCl of $2\frac{1}{2}$ molecules per litre, 45 c.c., distilled water, 72 c.c., sulphite of soda, 5 drops.—On the identity of surra and mbori: A. **Laveran.** It has already been shown that morphologically the trypanosomes of surra and mbori were nearly identical, and also that animals which had been rendered immune to surra were practically immune to mbori. In the present paper it is shown that an animal which has acquired immunity for mbori is also immune for surra, and hence the conclusion is drawn that the trypanosomes in these two diseases belong to the same species. The trypanosome of mbori is a less virulent variety of *Trypan. evansi.* —Observations on the sun made at the Observatory of Lyons with the 16 cm. Brunner equatorial during the first quarter of 1905: J. **Guillaume.** The results are summarised in three tables showing the number of spots, the distribution of the spots in latitude, and the distribution of the faculæ in latitude.—On isothermal surfaces and a class of envelopes of spheres: A. **Demoulin.**—On some generalisations of Picard's theorem: C. **Carathéodory.** —On the non-stationary movement of a fluid ellipsoid of revolution which does not change in figure during the movement: W. **Stekloff.**—On a transformation of certain linear partial differential equations of the second order: J. **Clairin.**—Reclamation of priority regarding an apparatus of M. Nodon for examining the solar protuberances at any time: Antoine **Sauve.**—On the propagation of light in a system in translation and on the aberration of the stars: G. **Sagnac.**—On the mechanism of the production and the nature of kathodic pulverisations: Ch. **Maurain.** The kathodic pulverisations appear to consist of moderately large particles, torn from the kathode by the shock of the α rays, and charged electrically, but with an e/m much smaller than for the projectiles constituting the kathode rays.—On the mobilities of the ions of saline vapours: G. **Moreau.**—On the respective spectra of the different phases of the electric spark: G. A. **Hemsalech.** Using the arrangement of apparatus described in an earlier note, the author finds that the electric discharge gives a line spectrum in non-ionised air and a band spectrum in ionised air. It is shown that a single oscillation is capable of producing and rendering luminous the metallic vapour.—The sulphates of samarium: Camille **Matignon.** The methods of obtaining the acid and basic sulphate from the neutral sulphate are given, together with the properties of these salts.—The action of acetylene on iodine pentoxide: Georges F. **Jaubert.** Acetylene is quantitatively oxidised to carbon dioxide by iodine pentoxide at 80° C. In the estimation of carbon monoxide in the air by the iodine pentoxide method, it is therefore necessary to ensure the absence of acetylene by appropriate reagents.—The action of glucose on selenious acid: MM. Œchsner **de Coninck** and **Chauvenet.** In the reduction of selenious acid by glucose, a red amorphous colloidal variety of selenium is produced, insoluble in carbon bisulphide. At 100° C. it is partially converted into black selenium.—The action of ammonia gas on the tribromide and triiodide of phosphorus: C. **Hugot.** A yellow amide of phosphorus is formed by this reaction at low temperatures; at higher temperatures it is decomposed, phosphorus imide being formed.—On the methods employed by the Arabs to get metallic lustre on enamels: L. **Franchet.**—On a new mode of preparation of barium: M. **Guntz.** The purest metal obtained in previous work contained 98·5 per cent. of barium. If this is converted into the hydride, and the latter heated *in vacuo* at 1200° C., the sublimed metal is crystallised and of 99·5 per cent. purity.—On some new derivatives of pentabasic phosphoric acid, $P(OH)_5$: P. **Lemoult.**—Syntheses of derivatives of 1:4:7 symmetrical heptanetriol: J. L. **Hamonet.**—Products of the hydrogenation of carvacrol: Léon **Brunel.** An account of the results obtained by the application of the Sabatier and Senderens method to carvacrol.—Some liquefying and hydrolysing actions of starch: P. **Petit.**—On the presence of trachytes and hypersthene andesites in the Carboniferous strata of Corsica: M. **Deprat.**—On *Raphia Ruffia*, a wax-producing palm: Henri **Jumelle.**—On an important variation of the tuber of *Solanum Maglia*: Édouard **Heckel.** Experimental work tending to confirm the view of de Candolle that this is the wild species from which the cultivated potato is derived.—On the use of manganese as a manure: Gabriel **Bertrand.** An account of some experiments, made on the agricultural scale, showing the beneficial effect of the addition of manganese sulphate as a manure.—The assimilation of carbon dioxide by the chrysalids of Lepidoptera: Mlle. Maria **von Linden.**—On the parallelism between phototropism and artificial parthenogenesis: Georges **Bohn.**—On the independence of metamorphosis and the nervous system in batrachians: P. **Wintrebert.**—On the inoculation of cancer: M. **Mayet.** The soluble products obtained from a cancerous tumour in man, free from solid matter by filtration through porcelain, and injected into a dog, gave rise to a cancerous growth. —The pathological nature of the Holmgren canals of nerve cells: R. **Legendre.** The author's views are in direct opposition to those of Holmgren concerning the function of the cavities in nerve cells, and he regards them as pathological in nature.—On the discovery of Amphibia in the Coal-measures of Commentry: Armand **Thevenin.** —Magnetic observations at the Observatory of Ebre on the occasion of the eclipse of the sun of August 30, 1905: P. **Cirera.**

January 2.—M. H. Poincaré in the chair.—On the estimation of carbon monoxide in air by iodic anhydride: Armand **Gautier.** With reference to the note by M. G. Jaubert in the last number of the *Comptes rendus*, the author points out that he published this fact in 1898, and has also shown how to correct for the error introduced into the determination by the presence of acetylene. Acetylene does not occur in the air of towns. —New observations on the Pycnogonides collected in the Antarctic regions in the course of the expedition directed by M. Jean Charcot: E. L. **Bouvier.**—On the deformation of quadrics: C. **Guichard.**—On the mutations of some fossil plants of the Coal-measures: M. **Grand'Eury.** A *résumé* of the results obtained by the author during the last ten years.—Observations of Giacobini's comet (1905*c*) made at the Observatory of Toulouse with the 38 cm. Brunner-Henry equatorial: F. **Rossard.** Observations made on December 18 and 22, 1905, showing the positions of the comparison stars and apparent positions of the comet.—Provisional elements of Giacobini's comet (1905, December 6): E. **Maubant.**—Observation of Giacobini's comet (1905*c*) made with the 16 cm. Brunner equatorial at the Observatory of Lyons: J. **Guillaume.** Observations made on December 12, 1905. The comet appeared as a diffuse luminosity of 30″ to 40″ diameter. —Photographic study of the annular nebula in Cygnus, N.G.C. 6894: Gabriel **Tikhoff.** The details shown by the photograph are in general agreement with those published by Keeler, from the Lick Observatory. Theorem on entire functions: M. **Auric.**—A contribution to the study of photographic screens: J. **Renaux.** Remarks on the use of colouring matters for photographic screens.—Researches on the terrestrial field, carried out during the total eclipse of August 30, 1905: Charles **Nordmann.**—On the determination of the rare gases in natural gaseous mixtures: Charles **Moureu.** A diagram of the scheme of apparatus used by the author is given, together with exact details of working. Oxygen and nitrogen are removed by hot lime and magnesium mixture, hydrogen and hydrocarbons by heated copper oxide, moisture and carbon dioxide by phosphoric anhydride and soda lime respectively. The last traces of nitrogen are removed by metallic calcium.—On the heat of fusion of ice: A. **Leduc** (see p. 254).—On the synthesis of the amido-acids derived from the albumens: L. **Hugounenq** and A. **Morel.**—The structure of plants developed in the light, without carbon dioxide, and in presence of organic materials: M. **Molliard.** The essential characters of plants cultivated under the above conditions are a structure resembling that of the subterranean organs and the formation of tissue with plurinucleated cells.—Symbiosis of orchids and several endophytic fungi: Noel **Bernard.**—On the copepods collected by the Charcot expedition and communicated by M. E. L. Bouvier: M. **Quidor.**—On a new micro-

sporidium, *Pleistophora macrospora*: Casimir **Cépède.**—On the intimate structure of the protoplasm in the Protozoa: Emmanuel **Fauré-Fremiet.**—A respiratory apparatus for the exploration of places filled with irrespirable gases: M. **Guglielminetti.** The apparatus consists of three parts, the bottle of compressed oxygen, the regenerator and cooler, and the respiratory mask. Illustrations are given showing a diagrammatic arrangement of the whole apparatus, and its position in actual use. Its weight is 13 kilograms.—Observations made on Mt. Blanc on the effect of altitude on the blood: H. **Guillemard** and R. **Moog.**

DIARY OF SOCIETIES.

THURSDAY, JANUARY 11.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Charing Cross Company's City of London Works: W. H. Patchell (*Conclusion of Discussion*).

LONDON MATHEMATICAL SOCIETY, at 5.30.—On the Diffraction of Sound by Large Cylinders: J. W. Nicholson.—On the Monogeneity of an Algebraic Function: Dr. H. F. Baker.—On the Expression of the so-called Biquaternions and Triquaternions with the aid of Quaternary Matrices: J. Brill.

FRIDAY, JANUARY 12.

THE HIGHER TELEOLOGY.

The Interpretation of Nature. By C. Lloyd Morgan, LL.D., F.R.S. Pp. 164. (Bristol: J. W. Arrowsmith; London: Macmillan and Co. Ltd., 1905.) Price 2s. net.

PROF. LLOYD MORGAN stands as a daysman between the naturalistic and the teleological interpretations of Nature, and the result of his arbitration is that both are valid, though neither by itself is satisfying. Naturalism aims at an analysis of occurrences in terms of the simplest possible formulæ—mechanical by preference—at a genetic description of the stages by which any particular configuration—the solar system, the scenery of Scotland, the simplest organism, Man and his mind—has come about. "It finds its principle of unification in the universality and inter-connection of world-events; it works inwards from external nature to the life and mind of man which it interprets as expressions of natural law." It is a stern way of looking at things, knowing nothing of beginnings or ends, never asking "why?" and never really answering even the question "how?" It flourishes William of Occam's razor, searching as he who shaved Shagpat for the periodically sprouting "identical," "principle" or "entity" to lop it off. It speaks not willingly of "causes," but deals with "antecedent conditions." "It regards the state of the whole universe at any given moment as a configuration of very great complexity, involving accelerations of many different orders co-existing in natural relationship, and it believes that the cause or condition of this configuration is that of the preceding moment, while the configuration of the succeeding moment is its effect. This involves a splendid act of faith, for it assuredly outruns what can, in the present state of knowledge, be definitely proved."

While many thinkers have sought to stay the progress of the triumphant chariot of Naturalism by exhibiting notices "No road this way," the chariot-drivers have paid no heed, but have gone nonchalantly on through the policies of Life and Mind, of Morals and Society, only pausing, as courtesy demanded, to say that they were giving no explanations, merely genetic descriptions. What is particularly interesting in Prof. Lloyd Morgan's attitude is that he wishes them God-speed, and is entirely disinclined to call a halt at any particular difficulty in the way of naturalistic formulation. It is true, he says, that the antecedent conditions of the genesis of protoplasm, for instance, are unknown, but they may not remain unknown, and "those who would concentrate the mystery of existence on the pin-point of the genesis of protoplasm do violence alike to philosophy and to religion." Or again, in reference to the naturalistic doctrine of the ego, that what we call mind is, from the restricted point of view of scientific psychology, the name we apply to a sequence of mental configurations, the author writes:—"But—it can't be proved. Never mind that. Some day it may be proved. And in any case to believe more than can be reduced to actual demonstration is not only a characteristic of human nature, but often one of the prime conditions of progress." It is evident, then, that this arbiter fully appreciates the naturalistic universe of discourse, and has no timidity in wishing that its ideal of formulation may be realised. For in proportion to the realisation of the naturalistic aim, which is to formulate our routine of experience in terms of the simplest possible ideal constructions, in proportion to its disclosure of determinate evolution all along the line, in proportion to its elimination of "purpose," "causal agency," and "end" from its universe of discourse, it will become clear that this mode of interpretation, however necessary and valuable for scientific workmanship, is too partial and abstract to satisfy those who feel that the purpose of their life is the most intimate and fundamental reality of which they have any knowledge. In other words, it is the aim of Lloyd Morgan's eirenicon "to show that a belief in purpose as the causal reality of which nature is the expression is not inconsistent with a full and whole-hearted acceptance of the explanations of naturalism within their appropriate sphere."

This little book deals with big questions, and many who have pondered over them will be grateful to the author for the lucidity of his argument, which is an expression of his own clear vision, and is also perhaps partly due to the fact that the book took shape as the Lowell lectures for 1904. Many will be grateful, we believe, for more than the pleasure of reading a vivid and stimulating course of lectures, namely, for a liberation from the obsession of a mechanistic outlook. The author expounds the naturalistic scheme with great sympathy, while disclosing its implications and limitations, but he maintains convincingly that "a complete and satisfactory interpretation of nature is, so far as it is attainable by man, partly scientific and partly metaphysical." We look, as it were, for a greatest common measure as well as a lowest common denominator of the fractions of reality which make up our experience. We cannot remain satisfied with a description of the observed moves among the pieces on the chequered chess-board of experience; we cannot but ask "how there comes to be a game to be played, and when this is settled how, or by what unseen agency, castles and knights and pawns are moved, each with a distinctive path, across the board." But this is beyond science; it is the other side of the shield; and the problem is:—By what ideal construction, valid in reason and valid in life, can we supplement the partiality of the naturalistic outlook? In a way of his own the poet feels that the whole universe "trembles with song"; the artist in his outlook, certainly not the least sane, has as little use for mechanistic categories as the mechanist has for wood-nymphs; the religious mood sees the iron chains of determinate evolution transmuted into golden chains which bind all things about the feet of God. But what more universal outlook is there for plain men dwelling in tents?

The answer given in this eirenicon is simple in expression but far-reaching in its outcome. It is that

"purpose is that of which all determinate sequence is the phenomenal expression." "Naturalism proclaims that I am just a little bit of nature, differentiated from the rest, a minute cluster of phenomena in relation with the total remainder of phenomena, a tiny, if somewhat complex configuration under the influence of the major configuration of the universe." But "I cannot do away with the conviction that there is something within me which unifies and relates and orders the configurations, something which is the source of my conception of causal agency. It is what I understand by *purpose*." . . . "But why should I suppose that the causal agency which, as purpose, underlies my own private and peculiar configuration, is of a different order of being from that of which nature at large is a manifestation. Just in so far as I *am* one with nature, and therefore in physical relationship with other manifestations in terms of matter and energy, is the purpose of my being one with the purpose which underlies the manifestations of nature, and am I in spiritual relationship with a wider and richer purpose which is thus manifested."

We agree so heartily with this higher teleology that we have no criticism to offer. We doubt, however, whether it is necessary to deal so generously with the naturalistic interpretation in its mechanistic expression as the author has seen fit to do. It may be well methodologically to deal with it as an ideal, but we cannot help feeling that its realisation is very far from being within the sphere of practical politics. Our other difficulty is that we cannot think of the concept purpose except as related to personality, except as an attribute or aspect of a larger reality still, which thinkers of all ages have spoken of as "Spirit."

J. A. T.

TWO BOOKS ON THE SOIL.

Bodenkunde. By E. Ramann. Second edition. Pp. xii+431. (Berlin: Springer, 1905.)

Soils and Fertilisers. By Prof. H. Snyder. Second edition. Pp. x+294. (Easton, Pa.: The Chemical Publishing Co., 1905.) Price 1.50 dollars.

DR. RAMANN'S treatise on soils, which has grown out of an earlier book on forest soils published in 1895, is of very different type and design from such books on the same subject as have appeared in English. In the first place, a considerable portion of the book is occupied with a somewhat generalised and academic consideration of the soil, its origin, its relation to climate and vegetation, its types, &c., in all of which the point of view of the geographer, the geologist, or the botanist is more to the fore than that of the farmer. Soils and their constituents and properties are classified and described as though they were a set of museum specimens, with little or no reference to their behaviour in the field. Indeed, the author has rather a passion for classification, and the work contains too many generalisations and definitions of the following kind, which are accorded the dignity of large type.

"*Bodenkraft* is the sum of all the chemical and physical properties of the soil. *Fruchbarkeit* is the relation between *Bodenkraft* and the development of plants. *Ertragsvermögen* is the relation between *Fruchbarkeit* and climatic factors in their action upon plant colonies or single kinds of plants."

Such definitions sound well in lecture, and serve to fill the industrious listener's notebook, but they do not help him much in the study of the real thing.

Similarly, in those sections of the book dealing with the examination of soils, we get directions for the carrying out of this or that determination—chemical analysis, water capacity, specific heat, &c.—but of the interpretation of the results we hear nothing at all. We are not, in fact, instructed how to add up that sum which is to indicate the fertility of the soil. But in its own special line Dr. Ramann's book cannot fail to be useful to our workers at the scientific study of soils. It is particularly good in dealing with the part of the subject most neglected in Britain, the physical properties of soils, and the portion in which Dr. Ramann is perhaps specially interested—the study of forest soils—contains an excellent summary of work that is almost unknown here. Such matters as the growth of forest soils, the effect of the leafy covering on the chemical composition, the temperature and the water content of soils, are dealt with at length; as again in later chapters are the questions of zones and types of soil and their delimitation upon soil maps. As a book of reference to modern German research on the soil (French and English investigations are practically ignored) Dr. Ramann's treatise will be of considerable service to the specialist; for the agricultural student or the farmer it will not serve.

Prof. Snyder's little book has been constructed out of a series of notes supplied to the students of his classes at the University of Minnesota, expanded somewhat and made more complete by the addition of descriptions of laboratory experiments upon soils and fertilisers. Essentially, however, the book still consists of notes which will serve to remind the student of the matter dealt with in the lectures; they lack both the filling in and the elucidation that comes from the lecturer himself. Too many things are mentioned and left without any adequate explanation, as though the author were afraid to pass them by wholly without notice, yet knew at once that he could not afford the time or space necessary to develop them properly. The result is a book which fulfils its original purpose of lecture notes, but when taken by itself is dull and difficult to read, and, as we would contend, a mistake educationally. A text-book should not be a miniature encyclopædia, and though the teacher is well advised in making occasional excursions into higher work beyond the average reach of his students, it should be done by working out principles, and not by scrappy enumerations of more advanced investigations.

But instead of criticising a book for what it is not, it is fairer to try and appreciate what it does accomplish. Prof. Snyder is a well known member of the band of American experiment station workers who have done so much to advance the application of science to the everyday practical side of farming, and have succeeded in making the United States

farmer regard the investigator as his necessary helper in the conduct of his business.

In matters connected with the physics of the soil and its bearing upon the operations of cultivation the American workers have accumulated much novel information, and to this some of the chapters of Prof. Snyder's book form a good introduction. The requirements of the crop are treated from a sound general standpoint which never forgets that water and air, soil texture, and cultivation are perhaps the prime factors in plant production. In this country students are a little too apt to fancy that farming begins and ends with the application of artificial manures; we can recommend this book to them for the truer point of view, even though the conditions which regulate our use of manures are not quite the same as in America.

RECENT ASPECTS OF ELEMENTARY GEOMETRY.

The First Book of Geometry. By Grace Chisholm Young, Ph.D., and W. H. Young, M.A., Sc.D. Pp. xvi+222. (London: J. M. Dent and Co., 1905.) Price 1s. 6d. net.

Of late years a very remarkable change has been made in the theory of elementary geometry, the general effect of which has been to make it more abstract, and to reduce a great deal of it to the application of logic without any appeal to intuition. It has been realised that geometry must be based on the assumption of certain undefinable entities, of elementary relations between them, and a complete system of independent axioms. For the purposes of ordinary Euclidean geometry, it is probably the simplest way to assume the straight line as the one undefinable entity, and intersection as the elementary relation from which the notions of point and plane may be derived. What system of axioms we adopt will partly depend upon the nature of the geometry we study; for instance, the axioms which are necessary and sufficient for the purposes of projective geometry require supplementing when we discuss the theory of measurement.

It is the theory of measurement which presents the greatest difficulty at the present time. If we assume all the results of projective geometry, we may proceed as follows:—Taking any three points O, I, X on a line, we may associate them with the numbers (or indices) 0, 1, ∞ (where ∞ is the vague infinity of ordinary arithmetical algebra). We can then give a purely projective rule for finding a point on the line to be associated with any given rational number p/q; we thus get on the line a set of points corresponding to the whole field of rational numbers, and, moreover, the arrangement of the points corresponds to the arrangement of the numbers according to their magnitude; that is, if $m>n>p$, the point N lies on that segment MP which does not contain X. If we like, we can define the distance AB as being measured by $b-a$, where a, b are the indices of A, B. This satisfies the relation $AB+BC=AC$, but equal segments as thus defined are not intuitionally equal, except when X is "the" point at infinity on the line; and even then we cannot prove, but must assume the intuitional equality. Moreover, there are points on the line which do not have rational indices, unless, in spite of common sense, we assume that the points on the line form a discrete aggregate. Now in arithmetic we have a perfect continuous aggregate, where each irrational element separates all the rational ones into two complementary parts, respectively greater or less than itself. If we *assume* that all the points in the line which have not rational indices behave in a similar way, we have a complete correspondence between the succession of points on a line and the elements of the arithmetical continuum. So far as appears at present, this is a pure assumption; but if it is not made, anything like the ordinary theory of measurement seems to be impossible, for two distinct points ought to have a measurable distance, and the measure must be a number; if the two distinct points cannot be associated with two distinct numbers, how is their distance to be defined as a measurable quantity? Other difficulties arise in connection with transfinite numbers and their representation by point aggregates; but these are comparatively unimportant, it it is remembered that the assumption of the correspondence of points on a line with the arithmetical continuum involves a similar correspondence between the arithmetical continuum and the points on any finite segment.

It is very interesting to see how this recent theory has reacted on the question of teaching elementary geometry. Instead of tending to make it more abstract and more logical, it has done exactly the reverse; and the reason for this is not difficult to find. The notions of geometry, so far as it is distinct from logic, are derived from concepts, and these, again, from experience. There must be an intuitional basis for geometry; and although, from a logical point of view, it is desirable, *for any given species of geometry*, to reduce its necessary assumptions to a minimum, progress in geometrical invention is to be expected from those who cultivate their powers of observation as well as their logical faculties. One result of recent research has been to explode, once for all, the pretence that the "Elements" of Euclid present geometry in its most logical form; on the other hand, to try to teach beginners the subject in what would now be considered the most rigorous way would be certain to end in failure.

The book which has been written by Dr. and Mrs. Young illustrates very well what has just been said. Its main object is to awaken the pupil's mind to the ideas by which we classify the properties of space; this is done by directions in paper-folding, in dissection of areas, in the construction of solid models, and the like. At the same time, various theorems are stated and proved, so that the beginner may learn the difference between experimental and deductive geometry. As in the case of other text-books with a similar aim, the teacher will have to be careful to see that his pupil distinguishes proofs from verifications; *e.g.*, on p. 173 we have a proof that the angles of a triangle make up two right angles, while on p. 121 we have a verification in a special case.

There is no doubt that the kind of first course laid out in this book is the right one from a psychological point of view. A quite young pupil, actually carrying out its directions with the help of a sympathetic teacher, will obtain clear conceptions of geometrical facts in a way that is really interesting and fruitful. The apparatus required is of the simplest possible kind—paper, pins, a pencil, and a pair of scissors are all that are absolutely necessary, though a compass and a scale might be provided with advantage, except at the beginning of the course. The attention given to solid figures is a feature which deserves commendation; and above all there does not seem to be anything said that is likely to lead to misapprehensions, which have to be painfully corrected afterwards.

There are a few points of detail which might be attended to in another edition. The letters in the diagrams are too small; the figure on p. 151 does not correspond to the text; on p. 35, "This gives us another axiom" is quite illogical; and there are some technical terms which might have been spared. It must be remembered, too, that this is not a book for a beginner to *learn* in the old-fashioned way; it is intended to make him experiment and think, and the guidance of the teacher is essential. Assuming this, the book ought to be very useful, and lead to good results, even in the case of pupils who have little faculty for demonstrative geometry.

G. B. M.

LEGIBILITY AND VISUAL ACUITY.

Physiologie de la Lecture et de l'Écriture. By Emile Javal. Pp. xv+296. (Paris: Félix Alcan, 1905.) Price 6 francs.

THE title of this book, which is written by a distinguished ophthalmologist, is somewhat misleading. One would naturally expect such a work to deal with the neuro-muscular mechanism, central and peripheral, of reading and writing. In reality, it treats almost exclusively of the legibility of printed and written matter, and the physiological processes are investigated only in so far as they throw light upon this aspect of the subject, and give indications for increased facility and rapidity in reading.

In the first part of the book a brief historical account of epigraphy, writing, typography, stenography, musical notation, and writing in relief for the blind is given. Typography is illustrated by examples from Garamond (1540), adopted by Plantin, of Antwerp, and the two Elzeviers, of Leyden and Amsterdam respectively, from very elegant designs by Jaugeon (1704), and from the Imprimerie Impériale (Didot, 1811) and the Imprimerie Nationale (Marcellin Legrand, 1847). Theoretical considerations of visual acuity, treated in the second part, show that the visibility of a letter increases indefinitely with the illumination, whereas its legibility depends upon the neuro-epithelial mosaic of the retina, and is therefore independent of illumination above a certain minimum. Investigation of the mechanism of reading a line of print has shown that the eyes move in a series of jerks, in each of which a group of about ten letters is appreciated, the grouping being independent of the distance of the book from the eyes so long as this is consistent with legibility. Bar reading gives some indication of the relative part played by the two eyes when binocular vision is present. The difference of accommodation in different parts of a line when the book is held close to the eyes, as in myopia, is very appreciable, and must be taken into account in treatment; thus in a myope of 15 dioptres a line of 10 centimetres involves a difference of accommodation of about 7 dioptres. The characteristic features of letters are for the most part in the upper portion, so that attention is specially directed here; consequently it is easy to read with the lower halves of the letters covered, whilst the reverse occasions considerable difficulty. These considerations indicate some improvements in typography. They have been carried out in some designs prepared for the author by M. Ch. Dreyfuss. It will be admitted that the result is successful as regards legibility and rapidity of reading, though at no small cost to the artistic sense. M. Javal points out that nearly all the improvements are to be seen in the well known enamelled-iron advertisement of Willing; indeed, English printing as a whole compares favourably in his estimation with that of other countries.

The terrible misfortune of blindness overtook the author a few years ago, so that it is not surprising that he has given much attention to Braille type. Even those born blind rarely attain to a rate of 100 words a minute in reading, or 10 in writing. It is surprising to find that the tactile acuity of the blind is actually less than that of normal people; the reading finger tires rapidly, and though the acuity of other fingers is greater, they are comparatively useless for reading. The author gives valuable suggestions for improving and simplifying Braille type, as well as general instructions as to the hygiene of vision and of writing.

J. HERBERT PARSONS.

OUR BOOK SHELF.

Exercises in Quantitative Chemistry. By Harmon Northrop Morse. Pp. xx+356. (Boston and London: Ginn and Co., 1905.) Price 8s. 6d.

THE time when the sole desideratum in the training of the chemical student was the acquirement of greater or less proficiency in the processes of analytical chemistry has, happily, gone by. Courses of experimental work arranged with the view of familiarising him with the most important general reactions, the preparation of typical organic compounds, and the methods peculiar to physical chemistry are now recognised as the essentials of chemical training. The work under review has been written from this standpoint, and makes no attempt to present a course of work for the training of expert analysts.

Although much diversity of opinion must necessarily attach to the problem of the choice of an ideal course of exercises, the unbiased critic can have but little fault to find with the author's selection. At first sight the heterogeneous character of the sixty-four exercises creates an impression of a lack of systematic arrangement, but this is more apparent than real. The first eight chapters deal with the balance, the

barometer and thermometer, the calibration of apparatus for the measurement of liquids and gases, the preparation of standard solutions, the determination of specific gravity and molecular weights, and with the purification of substances. Analytical exercises involving gravimetric and volumetric measurements and the manipulation of gases are contained in the succeeding twelve chapters, the selection being such that the student acquires familiarity with a large number of different kinds of operations. Chapters dealing with the electrolytic determination of metals, the analysis of butter, and electrical heating appliances for laboratory use complete the work.

Much care has evidently been devoted to the text. The remarks on p. 167 in reference to Victor Meyer's vapour-density method are, however, quite unintelligible, and in the methods of butter analysis described no mention is made of the standardised apparatus and method of working which has been adopted in this country for the determination of the volatile acids. These, however, are blemishes of small import, and the book represents an addition to laboratory literature to which attention may be directed with confidence. H. M. D.

Handbook of Physiology for Students and Practitioners of Medicine. By Dr. Austin Flint. Pp. xxvi+877 and xvi plates. (London: Macmillan and Co., Ltd., 1905.) Price 21s. net.

THERE are reasons for congratulating the author of this book upon its appearance, and not the least of them is the cheery optimism everywhere displayed. The growth that has taken place in the subject in the course of the last half-century is no more remarkable than the courage with which this writer, at the end of that time, turns round to attempt its description. To old friends of his handbook this gallant effort must afford great pleasure. It is doubtful, however, whether, outside this circle, much influence can be anticipated for this volume, since it has many competitors appealing more directly to the market of the present time.

"It is the outcome of a desire to connect pure physiology with the physiology specially useful to physicians." Let it be said that there is but one physiology. The physiology, which is of use to medicine, is not an applied science with a wealth of knowledge accumulated in its special interest; it is the essence of the pure science of physiology. There are also anatomy and histology. It is useless to claim credit from an attempt to provide a judicious blend of these separated subjects, since they are now more conveniently, and usually, studied separately. In this case, also, the standard of the extraneous matter is such as in no way to raise the standard of the general contents of the book.

As to the treatment of the more legitimately included contents, much can be said briefly.

The additions which have been made to knowledge in the last twenty years have made their bow to the author of this book, and have had the honour of an introduction. The names on their visiting cards have been forgotten; their inventions have been expressed at such hurried interviews as frequently to have escaped comprehension. The fact that they have called in such numbers has, however, made an impression, of which this new edition forms the record. The additions of recent years are, however, of such importance that nothing short of a complete—even if concise—consideration of their nature will suffice. The kindly sketched shadows, which here vaguely occupy the space that ascertained facts should definitely fill, render it impossible to recommend this book for general reading. J. S. MACDONALD.

Penrose's Pictorial Annual. Vol. xi. The Process Year Book for 1905–6. Edited by William Gamble. Pp. xvi+168. (London: A. W. Penrose and Co., Ltd., 1905.)

LAST year, in bringing to the notice of our readers this annual illustrated review of the graphic arts, we suggested that the standard of the volume in every respect was so high that it would be exceedingly difficult to eclipse it in the future. We were, however, wrong in our surmise, for the present volume surpasses those that have preceded it and illustrates the high state of efficiency of processes in use at the present time.

In the production of such a volume the task of the editor was no light one, but with his large acquaintance with all process methods he has given us an excellent survey of the latest achievements in process work. As in previous issues, we have a number of most interesting articles on various methods of procedure and allied subjects, and mingled with them is a host of first-class illustrations indicating the type and quality of work that can be accomplished by the various processes now available. To mention a few of the host of illustrations, attention may be directed to the frontispiece, a specimen of power-press printed copper etching by Bruckmann, of Munich, examples of work with the metzograph screen, the new four-colour process of Mr. C. G. Zander, and the spray-relief process of the aërograph which illuminates the front of the cover of the volume. The reader must, however, refer to the book itself if he wishes to revel in high-class illustrations, for no object would be gained in referring any more here to the numerous pictures.

In concluding, one cannot but congratulate all those concerned in the production of this really beautiful volume. The book should not only be in the hands of all process workers, but in the possession of photographers and others interested in book illustration.

Philips' Large Planisphere. Designed by H. Gewecke. (London: G. Philip and Son, Ltd.) Price 6s.

MOST students of the aspects of the heavens are familiar with the small circular planisphere having a revolving disc which can be adjusted to show the stars visible at any time of the year. The new planisphere now available is constructed upon the same plan as the earlier one, but its diameter is about twenty inches, and some changes have been made with the view of adding to its usefulness. The horizon can be taken off so that the whole of the chart can be seen if desired. A graduated strip is arranged across the chart, and by means of it the position of an object can be found when the right ascension and declination are known. The scale of right ascension on the outer edge of the circular chart is in degrees, but it would have been more conveniently expressed in hours and minutes in the usual way

The chart shows all the stars visible to the naked eye from the north celestial pole to 33° south of the celestial equator. The distortion is very great in some parts, and it is difficult to identify a few of the groups on this account and because the spots representing bright stars are so large. Fourth magnitude stars are represented by rings, and the effect is very unsatisfactory. A chart of this kind should aim at conveying a more or less faithful impression of the appearance of the stellar sky, but these white rings on a blue ground spoil the picture and ought not to have been introduced. Though the chart is said to have been "designed both for beginners and advanced students of astronomy," we are afraid that beginners would find it very confusing, and that working observers of the heavens would derive little real assistance from it.

Lehrbuch der Meteorologie. Second edition. By Prof. Julius Hann. Pp. 642. (Leipzig: Herm. Tauchnitz, 1905.) Price 24 marks.

In the year 1901 the author of this volume published the first edition, and on its appearance it was universally announced as the "classic" of meteorological literature. The work itself was a veritable mine of information, and the host of reference to original sources made it an absolute necessity for anyone dealing with this science to have it in his possession.

We have now before us a second edition. In this the author has made considerable alteration. In the first place, the size of the volume, as regards amount of matter it contains, has been very much reduced, a host of original references have been dispensed with, and the subject is dealt with in a more brief form. So rapid has been the progress of meteorological science, and so many have been the changes in ideas on numerous fundamental issues, that in many places this matter has had to be completely overhauled. Thus, to take one instance, namely, the investigation of the upper air by means of kites, balloons, and *ballons-sondes*, new light has been thrown on the movements of atmospheric currents, and innumerable data collected relating to temperature, pressure, and other elements in the higher strata.

The above is one of many cases where reconstruction has been rigorously carried out. Further, the insertion of all this, the latest, material has necessitated a great number of new references, so that the present volume with regard to these may be considered as a supplement to the first.

Several new and useful tables have been inserted in an appendix, one of these being a table of mean monthly and annual temperatures of 143 places in different parts of the world.

In the text are eighty-nine figures, nine autotype plates, and fourteen charts. The get-up of the book is of the same high standard of order as that of the first edition, the paper and printing being all that could be desired.

The volume should be in the hands of everyone who is in any way interested in meteorology, and is another very valuable addition to our meteorological literature by the master of the subject.

The Uses of British Plants. By Rev. Prof. G. Henslow. Pp. vi+184. (London: Lovell Reeve and Co., Ltd., 1905.) Price 4s. 6d. net.

About forty years ago a book was published on the "Useful Plants of Great Britain," written by C. P. Johnson and illustrated by J. E. Sowerby. Judging from the few copies one meets with, there has not been in the past much demand for information of this nature, but there is some indication of increased interest being taken in economic botany. The arrangement adopted by Prof. Henslow, in which he follows the nomenclature and order laid down in Bentham's "British Flora," accompanied, too, by the same set of illustrations, makes this practically a companion volume. Owing to the cost of production or the discovery of better substitutes, several plants once grown in the British Isles for their products have gone out of cultivation; the dyes produced by Rhamnus, Genista, and Rubia have been superseded by aniline dyes, and very few woad mills remain; one of those still existing was described in NATURE, November 12, 1896; nettle-cloth is not likely to be revived unless the term is applied to the material produced from rhea or the Nilgherry nettle, two exotic Urticaceæ. Such productions, and the cultivation of certain plants formerly reputed to be efficacious, are mainly interesting on account of their historical association, and with these the author deals sufficiently fully; also he has given a good deal of space to the derivations of the Latin names. On the other hand, he might have enlarged with advantage in the case of those plants which are still cultivated or which are closely allied to plants of economic value. The book is restricted to flowering plants.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Cheirality of Form of Crystals of Epsom Salt.

In studying the optical behaviour of the optically active biaxial crystals of zinc sulphate ($ZnSO_4 7H_2O$) and Epsom salt ($MgSO_4 7H_2O$), I found that the rotation (which, the crystal being trimetric, is the same for each optic axis) was to the left in all the thirteen crystals that I prepared. I then turned my attention to the crystalline form, which affords a more rapid means of determination of the cheirality, and is, moreover, applicable to small crystals. In the case of Epsom salt, twenty-two crystals were examined; sixteen of them were found to be positive, six doubtful, while not one was found to be negative. The crystal accepted as positive is that of which a diagram is given in Watt's "Dictionary of Chemistry" (vol. ii., p. 150, diag. 282, 1883). In examining the form, the smallest of the faces $+P/2$ and $-P/2$ was looked for, and then considered as belonging to the set of small faces, even if, as occasionally happened, others of the same set were large. The cheirality of form of zinc sulphate crystals is not marked enough to permit of any certainty of identification. The reason for this constant selection by the substance of a particular one of the two possible forms is perhaps that the crystallisation may have been occasioned by particles of organic dust that are themselves cheiral.

H. C. POCKLINGTON.

Deposits on Telephone Wires.

At East London, in the Cape Colony, one of the inhabitants recently complained that two telephone wires passing over his roof, an iron one, were seriously injuring it, and asked that they might be removed at once, and the building re-roofed at the cost of the Government. In support of his statements he referred to some lines of a whitish colour on the roof immediately under the wires. Many theories were advanced, one being that the moist sea air laden with salt had condensed on the wires, and that when the moisture had evaporated the salt had been shaken loose by the vibration and fallen on the roof, forming in time the lines referred to. The officials on the spot stated that they could taste the salt; but on some of the deposit being removed from the roof the iron was found to be quite intact. On the powder being analysed not a trace of salt or of any chloride, soluble or insoluble, could be found, and the result of the analysis showed the deposit to be nothing but silica, with very faint traces of iron and lime. The sand, a fine powder, must have been blown on to the wires when they were damp, and on evaporation of the moisture taking place have fallen on the roof owing to the vibration of the wires.

A SUBSCRIBER.

Sounding Stones.

Apropos of Mr. Tingle's letter of last week, it may be of interest to note that fairly good specimens of "sounding stones" occur at Corick, on the borders of the barony of Erris, co. Mayo. The bridge at this village is known as the "musical bridge," from the fact that stones which form the coping of the parapet give out a musical note when struck with a piece of stone or metal.

T. DILLON.

Ballina, co. Mayo, January 8.

MORE ABOUT JAPAN.

THE interest that has been awakened in Japan through her wonderful exploits in the war against Russia makes a book on her systems of fighting—both ancient and modern—particularly welcome when military experts are still marvelling at the perfection of her organisation in war time, bringing as it has done the success which follows as the natural result of attention to the smallest details.

In "The Fighting Man of Japan"[1] we have a very interesting little book by Mr. F. J. Norman, who is eminently fitted to discourse on the "Exercises and Training of the Samurai," having passed many years in Japan as instructor to some of the military and civilian colleges. As the author claims the indulgence of his readers in his preface, it is perhaps hardly fair to notice the grammatical errors that occur here and there, and after all they do not alter the interest of the book; but it would have been advisable to omit the blatant advertisements of a certain jujitsu school both at the beginning and end of the book, for the especial benefit of which the author confesses to have written his work.

The book is divided into four chapters, each of which deals with a separate subject. The first gives a rapid sketch of Japanese military history dating from 1543, which is as far back as our European knowledge of it extends, and incidentally giving a description of the spirit which animated the "Samurai" of old—and a very different one, it would appear from Mr. Norman's account, from that which guided our knights and crusaders; but East is East and West is West, and however much the Orientals assimilate our ideas of civilisation and education, the spirit will remain unaltered; their ideals and ours will for ever be as far distant as the poles. One example of this is enough:—"The bushi (or warrior) . . . held to the maxim that 'all is fair in love and war,' and scrupled not to resort to devices of the most dishonourable kind in order to gain a desired object"; and in the case of a hand-to-hand fight, were his opponent to fall or lose his sword this was regarded as the best possible occasion for hacking at him while he was down and unable to defend himself.

Mr. Norman considers the Dutch to have been the first to attempt to train a Japanese naval force, although he allows that the Portuguese and Spanish friars of the sixteenth century must be credited as the first instructors of the "Far Easterners" in the art of shipbuilding and the science of navigation. It is a remarkable fact not generally known that in the fifteenth and sixteenth centuries many modes of self-defence were practised by the Dutch that were almost identical with those used by the Japanese in the art of jujitsu. The question is, Did the Dutch take their ideas to Japan, or were they taught by the Japanese? A very interesting book illustrating many modes of self-defence that are the same as those used to-day by the Japanese was written early in the sixteenth century by one Nicolas Petter.

Speaking of the Portuguese and Spanish friars, the name of St. Francis Xavier stands out above all others on account of his wide personal influence among the Japanese, and this clever Jesuit made more converts to the Roman faith than have ever been made since by the missionaries of any other creed. That he loved the Japanese is proved by his writing to France early in the sixteenth century:—"These people (meaning the Japanese) are the delight of my soul." Unfortunately, his good influence was entirely destroyed by the arrival of European traders who exploited the unsuspecting Orientals in such an unprincipled way that they rose *en masse* and massacred almost every one of the foreigners, and after this regarded them with such distrust and detestation that it was many years before they could regain any foothold in the country.

An interesting chapter is that on the education of the naval and military officers, showing what a very fine sieve has to be passed through before the aspirants are thought capable and worthy of defending their country either as sailors or soldiers. The system of the fine sieve is of course applied to the officers only in each service; the rank and file receive a sound practical training, but "little or no attention is paid by the officers to the teaching of parade and show movements to their men. . . . Women not occupying the position in Japanese Society they do in the West, little or no pains are taken by the military authorities of the Mikado to cater for their amusement, and the result is one never sees any 'Agricultural Hall tomfoolery' in Japan."

FIG. 1.—Corps à Corps à la Japonaise. From "The Fighting Man of Japan."

The chapter on "Kenjutsu" deals with the affection the Japanese have always felt for the sword, and the great cleverness they exhibit when using it in a hand-to-hand fight. This cleverness would appear to be the result of much practice in "kenjutsu," for which a "shinai," or practice sword, is used, made from four strips of bamboo bound together at the

[1] "The Fighting Man of Japan." By F. J. Norman. (The Training and Exercises of the Samurai.) Pp. xii+79. (London: Archibald Constable and Co., Ltd., 1905.) Price 2s. 6d.

handle with a strong leather covering. One illustration here reproduced represents a *corps à corps à la Japonaise*, and, judging from the photograph, it is allowable to combine a trip with a hit, as one fencer is trying to knock his opponent over with a hit at the neck, at the same time taking his leg from under him with a sort of jujitsu trip.

The last chapter describes the sumō or wrestling of the Japanese—to many a most repulsive spectacle on account of the enormously fat bodies of the particular class of men who follow this profession; but a fight between two expert sumōtori is for the Japanese an event of almost national importance, and they flock in thousands to the huge amphitheatre in the centre of which the tussle takes place. The second illustration shows two combatants in a crouching position waiting for a chance to spring at each other.

The last few pages of the book are devoted to jujitsu, but as nothing new is said on this subject and the photographs are very poor there is no need to enter into detailed description. For the rest, a very pleasant hour may be spent over the perusal of this interesting little book.

FIG. 2.—Tachi-ai, or watching for an opening. From "The Fighting Man of Japan."

THE MOTION OF THE MOON.[1]

PER ARDUA AD ASTRA should be the motto for a cultivator of the lunar theory. There is no austerer road to prove oneself a man of mettle. *Incredibile studium atque indefessus labor* was Euler's summary upon it, and improvement of method since Euler's time has diminished neither *studium* nor *labor*. The work now brought to completion has occupied Prof. Brown (and a computer) since 1895, almost to the exclusion of other researches, and for some years before that he was busied with developing its methods. Moreover, the present stage is only a level whence he can take breath to proceed.

It is a fact to remember in mathematical astronomy that problems mathematically identical are often astronomically opposite as the poles. The theory of the moon from a geometer's point of view is simply the theory of one of the planets. It is the special values of the constants alone which distinguishes the case. The astronomer seeks a correct ephemeris, but a mathematical instinct seeks to solve the question as a case of the problem of three bodies, and Delaunay's two enormous volumes will show what labours may be undertaken to obtain full literal development of the moon's coordinates which shall be approximate enough to meet the needs of the observer. Unfortunately the expressions when obtained are in many cases so imperfectly convergent that they give neither a solution of the three-bodies-problem nor do they surpass the observations in precision, as calculation should. It seems that unless some wholly new device is found we must be content to separate the problem into two parts, leaving literal developments for special mathematical researches throwing light upon the problem of three bodies, such as G. W. Hill's investigations of periodic moons of different mean motions, and making the developments essentially numerical when they are designed to form the basis for tables, although by so doing the former part loses all observational interest and the latter nearly all that is mathematical. Prof. Brown's theory is neither wholly numerical like that of Hansen nor wholly literal like that of Delaunay. The mean motion alone is treated as numerical, the other constants as eccentricities and inclination appearing in literal form. This was a plan Adams always urged, and from time to time he made considerable studies to give effect to it. When there otherwise remain four parameters according to powers of which each coefficient must converge, it is clearly an immense gain to omit a fifth when that fifth is answerable for all the worst cases of slow convergence; and while the mean motion may be considered known, it is hardly the case with the other constants, the lunar eccentricity, for example, and the ratio of the mean distances of the sun and moon being uncertain within the limits over which debate ranges, so that it is essential that the calculator should not be tied to a single set of elements at the outset.

Besides this idea Prof. Brown's research rests upon two clear and solid supports. First is the use of rectangular moving axes of reference, which he points out—and otherwise it seems to have passed from memory—was developed by Euler. But perhaps as much as anything his success is due to the brilliant transformation of the equations of motion given by G. W. Hill. It detracts not the least from Prof. Brown's achievement that his main ideas and methods are derived from earlier masters. The tools were ready to hand for one who had the learning and judgment to use them. Anyone who has faced a similar task knows that there remain abundant calls for resource and invention, as well as for comprehensive patience, in fitting given plans together and working them out abreast in every remote ramification of a subject, without fidgeting about "originality."

The work is not yet at a stage to put to proof by calculation of an ephemeris, which indeed would need the calculation of lunar places for a great many years backwards and forwards to prove that it is superior to Hansen, or to Hansen *plus* Newcomb. But even now it is almost certain that it will be so. First its methods are more intelligible and above

[1] "Theory of the Motion of the Moon." By Ernest W. Brown, F.R.S. In the Memoirs of the Royal Astronomical Society, vols. liii., liv., lvii.

board than those of Hansen, and so there is a better chance of correcting the errors, which no mortal can altogether escape. Next the constants are not stereotyped, and if it is necessary to change them the effect can be made visible; and for a searching piece of evidence, Prof. Brown has shown already that his calculations remove the last shred of disagreement between the calculated and observed motions of the moon's apse. Finally, in a recent analysis of the Greenwich observations back to 1750, Mr. P. H. Cowell has given a most striking verification of all Prof. Brown's coefficients.

When Prof. Brown constructs his tables there is an error Hansen fell into which he may be trusted to avoid. In order to improve the agreement with observation, Hansen introduced a certain empirical element. An empirical correction is better than nothing, but it cannot be too clearly recognised that until it is furnished with a theoretical basis it is no more than a mathematical *memoria technica.* Certainly its place is not in a set of tables, the sole function of which is to expose correctly and fully the consequences of a clear theory and definite elements, with the view of testing the one and amending the others.

R. A. S.

THE CONTROL OF THE GAS SUPPLY OF THE METROPOLIS.

THE notification of the metropolitan gas referees just issued differs in several respects from that for the preceding year, a change necessitated by the provisions of the London Gas Act, 1905. For some years past the London gas companies have been asking for the revision of their Acts, with reference more especially to the system of testing to which their gas is subjected. In the early days of gas supply, when there was free competition and the consumer had the choice of more than one company, no testing was regarded as necessary, but when, owing to the amalgamation and consolidation of the gas companies, the supply became a monopoly, a system of testing the purity and illuminating power of the gas was instituted. The whole of the arrangements for testing London gas, with the exception of one or two points specially laid down in some of the Acts, are left to the discretion of the gas referees, originally appointed under the City of London Gas Act, 1868. It was alleged by the companies that the requirements of the referees were too stringent and out of touch with the modern developments of gas manufacture. In January, 1904, a departmental committee of the Board of Trade was appointed to inquire and report as to the whole system of gas-testing in the metropolis. At the inquiry the committee heard evidence from the gas referees, and from representatives of the London County Council, the Corporation of London, and each of the three gas companies concerned. It is noteworthy that no actual consumer was heard, although on one of the most important points dealt with by the committee, the question of sulphur impurity, the committee in its report says, "It does not appear that any complaints are made by the inhabitants of other districts on the ground that the gas thus unpurified causes injury to health or is more destructive to articles such as leather, &c., than it is supposed to be in London."

The report of the committee was almost wholly favourable to the companies. The mode of testing for sulphuretted hydrogen is to be relaxed, a test lasting three minutes being substituted for one spread over 15 hours, and all sulphur compounds other than sulphuretted hydrogen may be, and henceforth will be, left in the gas. The evidence of the companies as to the amount of sulphur impurity under the new conditions was to the effect that an average of 35 grains per 100 c.ft. or under might be expected, with the possibility of an occasional rise to 40, the maximum under the Acts just repealed being 17 grains in summer and 22 grains in winter. The figures for the amount of sulphur present in the gas supplied by the South Metropolitan Company during December last throw an instructive light on the value of this evidence, the weekly average increasing from 40·8 to 44·6 grains per 100 c.ft. with a single maximum of 61·3. On one occasion the Commercial Gas Company surpassed even this figure with a maximum of 70·2. It is clear, therefore, that the gas now to be supplied to London may contain about double the amount of sulphur contemplated by the departmental committee, and this is of interest in view of the fact that a Bill is now before Parliament promulgated by various provincial gas companies asking to be placed in the same position as the London companies as regards the removal of sulphur restrictions.

In one point the report of the departmental committee was favourable to the consumer. It recommended that the standard burner for testing the illuminating power of all qualities of gas should be the burner at present in use, the Sugg's London Argand No. 1, the gas to be burnt at the rate of five feet per hour. The gas referees in their present notification disregard this recommendation, and prescribe a burner devised by the engineer to the South Metropolitan Gas Company. The practical effect of this will be to increase the nominal illuminating power of the gas supplied by those companies having a 14-candle standard. It will be seen, therefore, that the new conditions are wholly favourable to the companies.

There remains one new point in the gas referees' notification, the prescription of a method of determining the calorific power of gas. The calorimeter, which has been devised by Mr. C. V. Boys, appears to be a distinct advance over its predecessors of the same type, and when it is installed in the testing stations systematic measurements of the calorific power of London gas will, for the first time, be on record, and will be available for the next battle on the gas question, calorific power *v.* illuminating power.

PROF. C. J. JOLY, F.R.S.

THE lamentable death of Prof. C. J. Joly at the early age of forty-one closes a career which was likely to influence favourably the mathematical side of astronomy. But his tenancy of the post of Royal Astronomer of Ireland and Andrews Professor in the University of Dublin was, alas! too short for him to make his individuality felt in the science with which he was connected by his occupancy of the chair, that has of late been held by Sir Robert Ball and Dr. Arthur Rambaut. The traditions of the office, and it may be the interrupted work of these astronomers, would naturally compel him for a time to follow certain definite lines which the previous occupants of the chair had approved. But his work in the department of pure and applied mathematics was of a high order and affords abundant evidence of originality and capacity.

From the time that Prof. Joly entered Trinity College, Dublin, his academic career was marked by his devotion to natural science, and mathematical scholarships and studentships were the natural preliminaries that led to a later fellowship. In this position he distinguished himself as a successful teacher of advanced science, but in 1897, when Dr. Arthur Rambaut was appointed to the office of Radcliffe observer, Dr. Joly

succeeded to the chair of astronomy, and his lectures and teaching were necessarily more limited.

Prof Joly will be best remembered by his loyalty to the memory of Sir William Hamilton, of whose "Manual of Quaternions" he prepared a new edition. He endeavoured to promote the study of this branch of mathematics in various ways, by his original writings, in which he sought to bring projective geometry within this special method of treatment, and by the support he gave to the International Association for Promoting the Study of Quaternions and Allied Systems of Mathematics. We are also indebted to him for the third edition of Preston's "Theory of Light," while many papers in the *Transactions of the Royal Irish Academy* testify to his industry and power.

Prof. Joly was elected a Fellow of the Royal Society in 1904; he acted as secretary to the Royal Irish Academy from 1902, and was a member of many learned societies. He was a delightful companion, with a memory well stored with anecdotes of Hamilton, of Airy, of Robinson, and many another worthy; as a teacher he had the power of interesting his class and awakening their energies, and all too soon he is removed from a circle which he loved, and a society that his abilities adorned. W. E. P.

NOTES.

SIR MOUNTSTUART E. GRANT-DUFF, G.C.S.I., F.R.S., who died in London on Thursday, January 11, at seventy-six years of age, will long be remembered by his "Notes from a Diary"—a series of fourteen volumes full of chatty reminiscences extending from January, 1851, to January, 1901. Many distinguished men of science, both at home and abroad, were met by the author during this period of fifty years, and in each of the volumes of his diary are preserved interesting anecdotes and pithy remarks made by his acquaintances in the scientific world. Sir Mountstuart was fond of natural history, and particularly of botany, to which he devoted much attention. The 117th volume of the *Botanical Magazine* was dedicated to him by Sir Joseph Hooker "as a slight acknowledgment of the valuable services which you rendered to botany and horticulture when Under-Secretary of State, first for India and then for the Colonies, and lately when Governor of the Madras Presidency." He was president of the Royal Geographical Society from 1889 to 1893, and a member of the Senate of the University of London in 1891. By his spirit of investigation and sympathetic interest in scientific work—attributes not possessed by many statesmen—Sir Mountstuart secured the kindly feelings of all who are concerned with the study of nature.

WE regret to see the announcement that Dr. H. J. P. Sprengel, F.R.S., the inventor of the mercury air-pump which bears his name, died on Sunday, at seventy-two years of age.

A MEMORIAL to the late Dr. George Salmon, F.R.S., Provost of Trinity College, Dublin, was unveiled on Friday, January 5, in the national cathedral of St. Patrick's, with which Dr. Salmon was officially associated during the best years of his life. An account of the ceremony appeared in the *Kensington Express* of January 5, from which we learn that the memorial consists of two windows in St. Peter's Chapel, the work of Mr. C. E. Kempe, depicting scenes in the career of St. Peter, and a medallion of Dr. Salmon, by Mr. A. Bruce-Joy, with a Latin inscription of which the following is a translation:—"That the name of George Salmon may abide in the memory of mankind this monument has been erected by his faithful friends and grateful pupils. Fellow of Trinity College, Dublin—afterwards Regius Professor of Divinity, and finally Provost, he was for thirty-three years Chancellor of this Cathedral Church. A mathematician both adroit and powerful, he probed with keen insight the beginnings of Christian history, and specially the origin of the New Testament Books; as teacher and councillor he was unwearied in the service of the Irish Church. Shrewd, courteous, serious, kindly. He was born in 1819, and died in 1904. The fear of the Lord is the distinction of wisdom, and before honour is humility."

A GIFT of 1000*l.* has been received by the Royal Botanic Society from a fellow of the society, Dr. Robert Barnes.

THE widow and children of the late Dr. von Siegle, of Stuttgart, have presented 50,000 marks in memory of the deceased to the chemical institute of the University of Tübingen.

PROF. EMIL FISCHER has been elected president of the German Chemical Society for this year. Prof. S. Gabriel, Berlin, and Prof. W. Städel, Darmstadt, have been appointed vice-presidents in succession to Profs. O. N. Witt and H. Caro, who are retiring, whilst Drs. F. Mylius and A. Bannon have undertaken the duties of the secretaryship in succession to Drs. C. Schotten and W. Will. The post of librarian to the society, which hitherto has been held by Prof. Gabriel, has yet to be filled by the president. The society's funds are estimated at 762,635 marks, whilst the A. W. von Hofmann fund has nearly reached 45,000 marks.

AT Christiania on December 29, 1905, there gathered together under the presidency of Mr. John Sebelien a number of men interested in questions of agriculture and scientific subjects to celebrate the acquisition of a national independence in the past year. A fund was opened for the purpose of fostering research in the subject of Norwegian agriculture, to which fund all Norwegians, both at home and abroad, are invited to subscribe. When the sum of 15,000 kr. (833*l.*) has been subscribed, it is proposed to invite prize essays on particular questions, and to reward Norwegian scientific work in certain branches of learning; and later still it is intended financially to aid research work in agricultural science directly.

A REUTER message from Naples states that on January 10 three streams of lava were pouring down Vesuvius on the side upon which is situated Cook's funicular railway. The railway was seriously damaged, and the lava had reached the lower station. At the same date Etna was also active, a large amount of volcanic ash being ejected from the principal crater.

THE Geological Society of London will this year make the following awards of medals and funds:—Wollaston medal to Dr. Henry Woodward, F.R.S.; Murchison medal to Mr. C. T. Clough; Lyell medal to Prof. F. D. Adams, of Montreal; Prestwich medal to Mr. W. Whitaker, F.R.S.; Wollaston fund to Dr. F. L. Kitchin; Murchison fund to Mr. H. Lapworth; Lyell fund to Mr. W. G. Fearnsides and Mr. R. H. Solly; Barlow-Jameson fund to Mr. H. C. Beasley.

DURING this month and next an exhibition of studies and effects obtained by current methods of colour photography will be open at the office of the *British Journal of Photography*, 24 Wellington Street, Strand, W.C. The

aim of the exhibition is to show results produced without the intervention of half-tone blocks, or the aid of printing machines. Flower and fruit studies, portraits, and landscapes are represented by three-colour prints produced by various processes, and among the subjects of transparencies are stained glass windows, diffraction grating spectrum, micro-organisms and crystals, butterflies, and a Lippmann spectrum.

WE learn from the *British Medical Journal* that an international exhibition will be held under the patronage of the King of Italy at Milan on the occasion of the opening of the Simplon Tunnel. It will include a section of hygiene embracing general hygiene, public health, sanitary services, rural and industrial hygiene. The exhibition will be open from April to November. The third International Congress of Medical Electrology and Radiology will be held at Milan on September 5–9. Information as to membership may be obtained from Dr. Herschell, 36 Harley Street, London, W.

THE *Weekly Weather Report* of the Meteorological Office for the current year, which commenced with the issue of the report for the week ending Saturday, January 6, on Thursday last, has some novel features. The verbal description of the week's weather is placed in a more prominent position on the front page, and a table of the accumulated temperature, rainfall, and sunshine in the various districts for the aggregate of weeks from the commencement of the current season, winter, is given, in addition to the usual tables for the week and the aggregates from the commencement of the calendar year. In the table of detailed statistics for stations the groups of names included in the meteorological districts are subdivided to facilitate the compilation of values for the divisions of the country adopted for agricultural purposes by the Board of Agriculture. There is no change in the part of the report devoted to the daily summary of weather over Europe, but at the end, in place of the tables of addenda and errata, there appears an entirely new table of observations in the upper air. The first issue includes the observations by Mr. W. H. Dines at Oxshott on the 3rd, 4th, and 5th of the month, the days of international cooperation, and those of a kite ascent by Mr. C. J. P. Cave at Ditcham Park on the first day of the year. The last disclosed a remarkable temperature inversion, obviously in the region of junction between an eastern and western supply of south-easterly wind over the British Islands as shown on the maps. The juxtaposition of these observations and the maps showing the distribution of pressure over Europe make the inclusion of the week's results for the upper air in the report a very interesting feature, and it is to be hoped that in succeeding weeks the new development may be as fortunate as in its first number.

THE *Times* of January 6 contained an interesting account of despatches which have been received from the American travellers Mr. R. L. Barrett and Mr. Ellsworth Huntington, who are conducting an expedition in the Tarim basin. The explorers have fully studied some of the river systems between Khotan and Keriya, and made additions to our knowledge of the Tarim basin which bring out the striking resemblance of the basin to an inland sea. The examination of the ruins of abandoned villages appears to have thrown a good deal of fresh light on the gradual desiccation of Central Asia within historic times.

IN the issue of NATURE for August 13, 1903 (vol. lxviii. p 347), an illustrated account was given of the tetrahedral cell kites designed by Dr. A. Graham Bell. We learn from a Canadian contemporary, the *Halifax Herald*, that Dr. Bell thinks he is a step nearer the attainment of his ambition to perfect a flying machine based on the tetrahedral kite principle. A new kite, constructed of 1300 tetrahedral cells, having a total area of 752 square feet of silk, making a supporting surface of 440 square feet, carried to a height of 30 feet, in a recent trial, not only its own weight of 61 lb., but also a load comprising flying lines, dangling ropes, and a rope ladder, making 62 lb. more, together with a man weighing 168 lb., a total altogether of 291 lb.

IN the *Engineering and Mining Journal* of New York of December 23, 1905, there is a reproduction of the selected design for the United Engineering Building, the building presented by Mr. Andrew Carnegie to the American Institute of Electrical Engineers, the American Society of Mechanical Engineers, the American Institute of Mining Engineers, and the Engineers' Club. The site has a frontage of 125 feet and a depth of 100 feet. The contract for construction was signed in July, 1905, and the contract limit is fifteen months to the date of expected completion. The building will serve the convenience of the four societies mentioned, and is also to furnish accommodation for other societies that have engineering or some other department of science as their principal object.

THE disaster at Charing Cross Station at 3.30 p.m. on December 5, 1905, caused by the sudden snapping of the tie-bar in the truss next to the wind-screen at the southern end of the station has caused much perturbation in engineering circles, and is dealt with at considerable length in the engineering journals. An excellent illustrated description of the roof is given in the January issue of the *Engineering Review*, and photographs of the fracture of the tie-bar are given in the *Engineer* and in *Engineering* of January 12. The tie-bar was nominally $4\frac{1}{2}$ inches in diameter, and it was found that at the point of fracture there was an imperfect weld, the iron having been united properly over only about one-third of the section, so that the stress at that point was three times as great as it was designed to be. In fact, it was more than this, for the sound metal, being at one side of the line of tension, was subject to a bending force, and the state of affairs was somewhat similar to a notched bar under bending stress. The verdict given at the coroner's inquest on January 8 was to the effect that the accident was due to the breaking of the tie-rod through an unforeseen flaw, and that no blame was attached to any of the railway company's officials.

WE have received a copy of part v. of the "Marine Fauna of Ireland," published by the fisheries branch of the Irish Department of Agriculture, in which Mr. W. M. Tattersall discusses the isopod crustaceans. Some difficulty has been experienced in getting a good series of these creatures owing to the fact that the majority are not pelagic, and are, therefore, not taken in tow-nets. Nevertheless, the author describes no less than ten species as new, half of which are made the types of new genera, while one is regarded as representing a new family.

AMONG the numerous and varied contents of the *Proceedings of the Indiana Academy* for 1904, attention may be directed to a remarkably fine series of photographs of the nests and eggs—in some instances also the young—of a number of the birds of the district in their natural surroundings. Two of these are of special interest as showing the nest of the little green heron, first with eggs and then with the downy young. In many cases great difficulty

must have been experienced in getting the camera into position, and in some instances the whole side of a tree-stem has been cut away in order to show the eggs. Indian ceremonies form the subject of several articles at the close of the volume.

IN the course of an account of the Hastings Museum, Worcester, published in the December (1905) issue of the *Museums Journal*, the curator, Mr. W. H. Edwards, takes occasion to emphasise the extreme importance of the development of local collections. "If there are among my hearers," he observes, "any who are in the happy position of having charge of a newly started museum may I strongly urge them to make their local, or county collections, in all branches, as complete as possible, as no opportunity should be lost in acquiring specimens which have any bearing on the past history of a district." These views accord with those that have on more than one occasion been advanced in our columns. In a second article in the same issue it is somewhat amusing to find an author urging that a proposed new institution should be, as regards the exhibited series, "unlike ordinary museums, where, as far as possible, every species, and even varieties, are represented." In how many museums, "ordinary" or otherwise, is such a series displayed, and where is there one which would hold it?

THE whole of parts iii. and iv. of vol. xxxiv. of Gegenbaur's *Morphol. Jahrbuch* are occupied by a long essay on the tympanic region of the mammalian skull, by Dr. P. N. van Kampen, of Amsterdam. The article is an expansion of an address delivered by the author in Amsterdam in 1904. Within the space of a brief paragraph it is quite impossible to do justice to its contents, and it must in the main suffice to direct the attention of those interested in the subject to the mine of information it contains. It is interesting, however, to note that the author regards the primitive condition of the mammalian tympanum as consisting of a small and often incomplete ring, with, at most, an imperfect ventral wall to the tympanic cavity, and that a close approximation to this condition is presented by Ornithorhynchus. The tympano-hyal is the characteristic mammalian element in this region, but the ento-tympanic is also regarded as peculiar to the group, and unrepresented among the lower classes. As regards the tympanum itself, the author considers it to be a special development from one of the elements—probably the supra-angular—of the reptilian compound lower jaw. The features presented by the region are held to be of considerable value in classification.

THE Carnegie Institution of Washington has published a volume of 193 pages, by Profs. W. O. Atwater and F. G. Benedict, giving a description of a respiration calorimeter with appliances for the direct determination of oxygen. The apparatus has been in process of development for twelve years, and has been designed with a view to a proper understanding of the metabolism or transformations of matter and energy in the body, by obtaining a knowledge of both total income and total outgo. After describing the calorimeter and the methods adopted for the calculation of results, the experiments with man are considered. Since the completion of the new apparatus, twenty-two experiments with five different subjects, covering a total of sixty days, have been conducted. These experiments lasted from one to thirteen days, during which time the subject remained enclosed in the calorimeter chamber. In general, each experiment was preceded by a preliminary period outside the chamber, during which the subject was given the special diet to be tested, and his habits of life were so modified as to conform with those to be followed in the chamber. The following determinations of intake and output of material were made in the experiments:—The intake consists of food, drink, and oxygen from respired air. The amounts are determined by weighing. The output of material consists of products of respiration and perspiration, urine, and fæces. In the measurement of intake and output of energy the intake is derived from the potential energy, *i.e.* heats of combustion of the food. The output consists of sensible heat given off from the body, the latent heat of the water vapourised, and the potential energy, *i.e.* heat of combustion of the unoxidised portions of the dry matter of urine and fæces. In certain cases, *e.g.* work experiments, a portion of the output is in the heat equivalent of external muscular work.

IN the *Bulletin du Jardin impérial botanique* of St. Petersburg, vol. v., part iv., Mr. N. Busch describes a new Aconite, section Napellus, and a new Delphinium. Both plants were grown in the garden from seed collected in Tibet by Mr. W. T. Ladygin. A list of the known species of Iris from Turkestan is contributed by Mr. and Mrs. B. Fedtchenko, including several new species all belonging to the section Juno.

DR. B. M. DUGGAR, formerly a member of the scientific staff of the United States Department of Agriculture, has for some years been experimenting on better methods of propagation of mushrooms than the present chance method depending upon natural virgin spawn. His latest results are published in Bulletin No. 85 of the Bureau of Plant Industry. No more certain method for germinating the spores has been devised than that discovered by Dr. Margaret Ferguson of adding a portion of mycelium to the culture; but the latest experiments proceed on a new line of producing virgin spawn from pure cultures. A portion of the inner tissue of a young selected mushroom is transferred to a sterilised compost in tubes, and the mycelium produced in this way under pure culture conditions is sown on bricks of manure.

TWO recent numbers of the *Transactions of the Academy of Science of St. Louis* deal with botanical subjects. In vol. xiv., No. 7, Mr. B. F. Bush presents a summary of the species of Tradescantia from Texas, in which he adopts the view that certain forms referred to *Tradescantia virginiana*, notably *Tradescantia reflexa*, should rank as independent species. In vol. xv., No. 1, Dr. L. Wittmack writes on our present knowledge of ancient plants. He mentions that some of the wheat found in Egyptian sarcophagi and in Asia Minor shows the characters of the wild grain, and that the barley is of the variety *hexastrichum*, having six rows in the ear. From Peruvian sepulchres two kinds of bean have been identified as the Lima bean, *Phaseolus lunatus*, and the French or haricot bean, *Phaseolus vulgaris*. The author pronounces in favour of American origin for the latter.

IT will be known to readers of NATURE that one of the principal objects before the botanical congress held in Vienna last June was to formulate satisfactory laws for regulating systematic botanical nomenclature. A concise account of the main questions under dispute, and of the alternative suggestions put forward, is given by Dr. H. Harms in *Naturwissenschaftliche Wochenschrift*, December 10, 1905. There were three principal points of contention,

these being the earliest date for reference of priority, the extent to which priority of genus name should be observed, and how priority of specific name is to be decided. The year 1753, in which Linnæus first established his system of binomial nomenclature, was accepted as the critical date; the difficulty with regard to genera was settled by the confirmation of a list of names that are too well established to be superseded, while the decision in the matter of specific names was a compromise between the German practice of adopting the earliest name and the Kew rule that favours the first correct binomial.

The growing of Egyptian and other varieties of cotton is, says a writer in the *Pioneer Mail*, being carried on steadily in Upper Sind. It is indicative of the difficulty of forecasting the future of a transplanted variety that "Yannovitch," the finest of the Egyptian varieties, but regarded as the most delicate of those experimented with, has suffered the smallest amount of deterioration in staple from the quality of the Egyptian grown product, and that Mitaffifi, which is considered the most robust, has shown the greatest amount of deterioration. The general results must, however, be considered as satisfactory in yield as compared even with the Egyptian crop, and by the figures the best Egyptian variety should prove 250 per cent. more profitable to the cultivator than the indigenous Sindhi variety.

According to a writer in the *Journal of the Society of Arts*, the rubber industry continues to expand rapidly. The imports of rubber last year were exceptionally large, and throughout 1905 the price was better than in the preceding year. It may be expected that before very long the supply will be ample for all demands. Not only are there immense tracts of rubber which remain untouched in Liberia and elsewhere, but the cultivation of the rubber tree is being rapidly extended. Java, for example, is planting extensively, and within the next six or eight years the exports from that island are likely to be very large. In Ceylon, too, and the Malay Peninsula, considerable tracts of country are being planted with rubber. The way in which the tree adapts itself to the various climatic conditions obtaining in different countries is almost unique in tropical cultivation.

Of the life of a born naturalist no better example could be given than the account of the late Prof. Federico Delpino contributed by his pupil Borzì to the *Atti dei Lincei*, xiv. (2), 9. Born at Chiavari (Liguria) on December 27, 1833, Delpino's delicate state of health resulted in his spending much of his early life in a garden, where he soon became absorbed in observing ants, wasps, and flowers. In 1850 he commenced, by his own choice, a course of mathematics at the University of Genoa, but his love of botany prevailed, and he determined to make that subject his life work. After a sea voyage to the east, which gave him an opportunity of making a collection of the flora of the Dardanelles, he was employed in office work under the Minister of Finance at Turin, and later (1865) at Florence, where he soon resigned his post to take a subordinate assistant's position in the botanical museum. Four years later he was appointed professor at the school of forestry at Vallombrosa, and in 1875 he became associate professor of botany at Genoa. Later he held appointments at Bologna and Naples. He died on May 14 of last year. Delpino, who was entirely self-taught, became one of the pioneers in the study of vegetable biology. He was an ardent opponent of Darwinism, although a study of Darwin's work on orchids led to his first paper on fertilisation of the Asclepiadaceæ, published in 1865. Other important contributions dealt with the relations between plants and insects, particularly ants, and several of his results were confirmed by the observations of Belt in Nicaragua. In botanical geography he published writings on the distribution of the Ranunculaceæ, and on the relations between Arctic and Antarctic flora. Several of his writings have been mentioned in the "Notes" columns of Nature up to quite recently. Another account of his life is given in the *Rendiconto* of the Naples Academy for May and June, 1905, and differs in one or two points of biographical detail from the preceding one.

We have received a copy of the twelfth annual report of meteorology in Mysore, for the year 1904, compiled by Mr. J. Cook, director of the service. It includes the results obtained at the observatories of Bangalore, Mysore, Hassan, and Chitaldrug, with diagrams showing the range of the principal elements; also mean values for the twelve years 1893–1904. The data for this important Indian area are very carefully worked up, and the volume contains a large amount of valuable statistics.

The tides of the North Sea have within recent years been the subject of investigation by Mr. J. P. van der Stok, and the results have been published in three papers by the Netherlands Meteorological Institute, "Études des Phénoménes de Marée sur les Côtes Neerlandaises" (Utrecht: Kemink & Zoon, 1905). The first of these papers consists of an analysis of the variation in the level of the sea. The second deals with the results of observations, made on board the Netherlands lightships, of the tidal currents; and the third contains a table of these currents, the corresponding velocity and direction of the wind at five different stations, and the date of the new and full moon for every month up to 1952. Mr. Stok more particularly directed his investigation to the horizontal movement of the water and the rotatory currents in the North Sea. There are two subjects in connection with the tides of the North Sea that more particularly require consideration—the effect of the tidal wave of great length moving along the coast inclined to the direction of its propagation; and why the wave that comes from the north-east of Shetland is propagated principally along the coast of Scotland. This, he suggests, is due to the rotation of the earth. Mr. Stok considers that the tides of the North Sea are well worth the attention of physico-mathematicians interested in hydrodynamics, as they afford a model for the study of the mechanics of the tides.

In a paper on fluorescence (*Journal de Physique*, December, 1905), M. G. Camichel deduces from experiments and theoretical reasoning connected with them that the coefficient of fluorescence of a fluorescent substance remains constant during the period of fluorescence, at any rate under the conditions of the experiments.

In the *Journal de Physique* for December, 1905, MM. Bouasse and Berthier discuss the elongation of wires by flexion, in particular in connection with the property that a wire which is incapable of being elongated more than 0·1 per cent by simple traction can be lengthened by as much as 10 per cent. or 20 per cent. by bending. Observations of the changes of microscopic structure, as well as of the torsional rigidity of the wire at various stages of the processes, seem to indicate that this discrepancy is attributable to want of homogeneity in the wire, the effects of which disappear when the deformation is made to take place point by point along the wire.

In the *Bulletin des Séances* of the French Physical Society, M. E. Haudié gives a brief illustrated account of

the method of determining the magnification of an astronomical or Galilean telescope by photography. The telescope is placed in front of a camera pointed at a distant object (a church spire), and measurements of the telephotograph thus obtained, as compared with the picture obtained with the camera alone, give the magnification.

Of the many important topics discussed in the *Economic Journal* for December, 1905, we find a note of eight pages on political economy in Germany, by Prof. G. Cohn, of Göttingen. In it we learn that thirty or forty years ago there were two schools of political economy, namely, on the one hand, the Free Traders, whose science was confined to a few very elementary principles and who appealed to the people, and, on the other hand, the economic teaching of the universities. At the present time the universities, strengthened by the high degree of freedom which their professors enjoy, play an important and ever-increasing part in determining public opinion on economic questions throughout the Empire. Indeed, the author concludes:—"We do not claim too much for our German Political Economy and our German Universities when we say that the spirit which rules them is as wide and many sided as it is active and far seeing."

From the point of view of the disintegration hypothesis of the nature of radio-activity, a brief note by P. G. Costanzo in the *Bolletino Mensuale* of the Italian Meteorological Society (vol. xxiv., p. 25) is of interest; it is stated that several lavas and solid deposits from Vesuvius and the solfatara of Pozzuoli which, on examination, were found not to exhibit any sign of radio-activity were equally destitute of any trace of helium.

For his inaugural address, delivered on November 22 of last year, Prof. R. Threlfall, as chairman of the Birmingham section of the Institution of Electrical Engineers, chose the subject "Some Problems of Electro- and Electrothermal Chemistry." The principal question dealt with was the conversion of carbon into the "non-conducting" variety, and Ludwig's recent attempts to produce diamonds on the large scale were discussed, principally by considering theoretically the probable conditions governing the inter-conversion of the various forms of carbon. Other subjects touched upon included the fixation of atmospheric nitrogen, the ionic theory, and the use of osmium and tantalum in incandescent lamps.

The final number (No. 7) of the second volume of the *Central*, the magazine of the Old Students' Association of the Central Technical College, well maintains the high level of its predecessors. It contains a photogravure of Prof. Ayrton, president of the association, whilst a special feature is the large number of photographs illustrating the articles contained in it. Of these articles we may mention an interesting account by Mr. A. A. Barnes of the work recently carried out in excluding the Nile from two of its three channels at Ashmant for purposes of land reclamation; a summary by Prof. Armstrong of the various researches made on camphor at the college during the past twenty years, indicating the widely ramified growth of the problem; and a description of several types of electromagnetic ore crushers by Mr. C. J. Guttmann. Two photographs of a new camphor-model illustrate Prof. Armstrong's article.

A brief note by F. Giolitti in the *Gazzetta* (vol. xxxv. p. 181) contains some interesting particulars with regard to the coagulation of colloidal solutions of ferric hydroxide, the observations forming an extension of the earlier ones of Péan de St. Gilles. Whereas a trace of any polybasic acid, for example sulphuric acid, added to the colloidal solution obtained by boiling ferric acetate with water instantly precipitates a flocculent "hydrogel" which is insoluble in water, a considerable quantity of a monobasic acid such as nitric acid has to be added to the colloidal solution before a precipitate is produced. The product in this case is a reddish powder which re-dissolves in pure water, and is hence a "solid hydrosol." The quantity of monobasic acid necessary for complete precipitation of the solid hydrosol appears to be fairly definite for a definite set of conditions. The character of the colloidal solutions of a substance, however, seems to depend very largely on the way in which they are prepared. Thus a solution of ferric hydroxide prepared by dialysis according to Graham's method gives on coagulation very different results from those obtained with the solution prepared from ferric acetate. Moreover, other colloidal solutions, such as those prepared from ammonium uranate, plumbic acid, and silicic acid, have certain features which characterise their coagulation. It seems necessary, indeed, in considering the general question of colloidal solution, to recognise that several distinct types of coagulation exist.

The adhesion of electrical contacts in delicate seismoscopes continues to exercise the minds of Italian seismologists. No other form of seismoscope can be made so sensitive as one which records electrically, but the force tending to separate the contacts is so small that the circuit sometimes remains closed. In the concluding number of vol. x. of the *Bolletino della Società Sismologica Italiana* Dr. Agamennone reviews all the devices which have been proposed to overcome the adhesion, and concludes that the only efficient one is that suggested by Dr. T. Alippi, of attaching a vibrator to the seismoscope, which shall act like the decoherer in wireless telegraphy, but adds that his experience in the observatory at Rocca di Papa shows the necessity of carefully adjusting the energy of this vibrator. If too energetic it may produce the very evil it is designed to cure.

The annual report of the Iowa Geological Survey has just been published at Des Moines under the able editorship of Dr. F. A. Wilder, the State geologist. It deals with the year 1904, and forms a handsome quarto volume of 560 pages with 10 folding coloured geological maps of counties, 7 plates, and 51 illustrations in the text. In addition to the State mineral statistics for 1904, and reports on the geology of Benton, Emmet, Palo Alto, Pocahontas, Jasper, Clinton, and Fayette counties, the volume contains an important report on the Portland cement industry and Iowa's natural resources with reference to that material by Mr. E. C. Eckel and Mr. H. F. Bain. The report shows plainly that the limestones and clays of Iowa are well suited for the careful study of the cement manufactures. Despite the large amount of material available and the convenient fuel and transportation facilities, no Portland cement plants have yet been established in Iowa, although a number are in operation in adjacent States.

We have received from the Home Office an advance proof, subject to correction, of the statement of fatal accidents and deaths in and about the mines and quarries of the United Kingdom during 1905. The total separate fatal accidents were 955 in collieries, 41 in metalliferous mines, and 94 in quarries.

Mr. William Heinemann has in hand, under the title of "A Handbook of Metabolism," an English translation of the second German edition of von Noorden's "Lehrbuch des Stoffwechsels," edited by Dr. Walker Hall, of Manchester.

WITH the title the *Australian Journal of Science*, a new periodical edited by Prof. Liversidge, F.R.S., is to appear during the present month. At first the journal will be issued monthly, but afterwards, if it meets with sufficient support, at more frequent intervals. Literary correspondence, and publications for review, should be addressed to the Editor, *Australian Journal of Science*, The University, Sydney.

THE thirty-third annual dinner of old students of the Royal School of Mines will be held on Friday, February 16, at the Hotel Cecil. The chair will be taken by Prof. S. Herbert Cox; and the opportunity afforded by the dinner will be taken to make a presentation to Prof. J. W. Judd on his retirement from the chair of geology. Subscriptions for this testimonial should be forwarded before the end of January to Mr. D. A. Louis, 77 Shirland Gardens, W., to whom applications for tickets for the dinner should also be sent.

THE publication by Mr. George A. Morton, of Edinburgh, at 3*s*. 6*d*., of an attractive edition of Hugh Miller's "My Schools and Schoolmasters" should serve to re-direct attention to the work of a geologist whose writings were in the middle of last century the means of attracting many persons to the study of natural phenomena. A biographical introduction to the volume by Mr. W. M. MacKenzie provides an interesting study of Hugh Miller's career as stonemason, bank clerk, editor, geologist, and author, and reminds the reader that this work of his was published in 1854. The stonemason who by his own unaided efforts could attain to such an acquaintance with the rocks of his native land as to become the author of "The Old Red Sandstone" should prove an encouragement to all students of science who are working in the face of great difficulties. This new re-issue deserves a wide popularity.

A BOOKLET by Mr. J. El. David entitled "Le Tunnel du Simplon" has been published by Messrs. Payot and Co., of Lausanne. Parts of the account have already appeared as articles in the *Gazette de Lausanne*. In view of an article which appeared in NATURE of November 9, 1905, p. 30, describing survey work of the Simplon Tunnel, it is unnecessary to do more than refer to the contents of the brochure. Before publication the text was submitted to the chief engineers in charge of the work, so that the book may be read with confidence as containing a correct account of the order of events. The biographical notices and portraits of the engineers in charge of the gigantic undertaking, and other numerous illustrations, add greatly to the value of this essay.

OUR ASTRONOMICAL COLUMN.

COMET 1905*c* (GIACOBINI).—A new set of elements and an ephemeris for comet 1905*c* appear in No. 88 of the Lick Observatory Bulletins; they have been computed by Mr. R. T. Crawford, of the Berkeley astronomical department, and the elements are as follows:—

$$T = 1906 \text{ Jan. } 22{\cdot}41845 \text{ G.M.T.}$$

$$\left.\begin{aligned} \omega &= 199^\circ\ 1'\ 28''{\cdot}8 \\ \Omega &= 92\ \ 2\ 00{\cdot}5 \\ i &= 43\ 38\ 36{\cdot}7 \end{aligned}\right\} 1906{\cdot}0$$

$$\log q = 0{\cdot}217605$$

The ephemeris shows that after perihelion (January 22) the comet's brightness will decrease rapidly, falling from 58·6 on that date to 22·7 on January 30. The positions (true) are given for alternate days during January, but only the three given below have been computed for dates subsequent to January 28:—

Ephemeris 0h. G.M.T.

1906	α (true) h. m. s.	δ (true) ° ′ ″	Brightness
Jan. 30·5 ...	21 53 28 ...	−25 44 25 ...	22·7
Mar. 1·5 ...	1 48 11 ...	−6 2 44 ...	1·5
April 2·5 ...	3 29 3 ...	+7 9 50 ...	0·3

Numerous observations of this comet are recorded in No. 4065 of the *Astronomische Nachrichten*. Dr. Jost, observing at Strassburg on December 30, 1905, found that the magnitude was about 5·0, and that the comet had a sharp definite nucleus and a tail about $\frac{3}{4}^\circ$ in length. On January 1 the magnitude was 4·0–5·0, the diameter of the nucleus 4″, and the length of the tail about $1\frac{1}{2}^\circ$.

A daily ephemeris, extending from January 13 to January 31, is given by Herr E. Strömgren in the same journal.

NEBULOSITY AROUND NOVA AQUILÆ.—Prof. Frost reports that a careful examination of the photographs of Nova Aquilæ No. 2, taken with the Bruce telescope at Arequipa on October 16 and 21, 1905, shows the Nova to be surrounded with a faint nebulosity nearly circular in form and extending to about 0′·4 on each side of the star. The exposure in each case was 120 minutes, and the nebulosity was independently confirmed by Mr. Manson.

As no such nebulosity appeared on the engraving given in vol. xxii. (p. 269) of the *Astrophysical Journal*, representing the Nova on September 21, 1905, Prof. E. C. Pickering suggests that it radiated from the Nova early in October, as was the case in Nova Persei No. 2. He points out, however, that, if it can be shown that the spectrum is peculiar, the apparent nebulosity on the Bruce photographs may be explained as being due to chromatic aberration which does not exist in the reflector, and would therefore not affect the earlier photograph (*Astronomische Nachrichten*, No. 4065).

THE FIGURE OF THE SUN.—Continuing his research on the variable figure of the sun, Dr. C. L. Poor has reduced the values of the solar diameter obtained by Schur and Ambronn, with the 6-inch Repsold heliometer of the Göttingen Observatory, during the thirteen years 1890 to 1902.

A detailed description of the methods of reduction is given in No. 5, vol. xxii., of the *Astrophysical Journal*, and the results tend to confirm those obtained in Dr. Poor's previous research, viz. that the ratio between the polar and equatorial radii of the sun varies periodically, the period being nearly the same as that of sun-spots. The amplitude of the variation is about 0″·2, the greatest difference between the extreme values of the quantity (polar−equatorial diameter) being 0″·5.

STELLAR MAGNITUDE OF THE SUN.—The results of an interesting research made by Prof. Ceraski at Moscow on the relative magnitudes of the sun and Polaris, Procyon, and Sirius, are given in No. 4065 of the *Astronomische Nachrichten*. During the day Prof. Ceraski photometrically compared the light received from Venus with that obtained from a reflected image of the sun, and then at night compared Venus with the stars named.

As a result he found that the sun sends us 290550×10^6 times more light than Polaris, 77630×10^6 times more light than Procyon, and 17045×10^6 more than Sirius. Taking the magnitudes of these stars as 2·15, 0·56, and −1·00 respectively, this gives −26·51, −26·66, and −26·67 as the stellar magnitude of the sun, and the weighted mean value becomes −26·59. As Prof. Ceraski objects to the obvious paradox in assigning a *negative* value to the sun's magnitude, he omits the *minus* sign and gives his result as "26·59 *super magnitude*."
